Contents

1. [Introduction to Apache Doris](#)
2. [Quick Start | GettingStarted](#)
3. [Alternative to ClickHouse](#)
4. [Alternative to Elasticsearch](#)
5. [Apache Doris vs Trino / Presto](#)
6. [Environment Checking](#)
7. [Cluster Planning](#)
8. [OS Checking](#)
9. [Deploy Integrated Storage Compute Cluster Manually](#)
10. [Deploy Doris Operator](#)
11. [Config Doris to Deploy](#)
12. [Deploy Doris Cluster](#)
13. [Access Cluster](#)
14. [Cluster Operation](#)
15. [Deploying on AWS](#)
16. [Connecting by MySQL Protocol](#)
17. [Connecting by Arrow Flight SQL Protocol](#)
18. [Overview | Table Design](#)
19. [Table Model Overview](#)
20. [Duplicate Key Model](#)
21. [Unique Key Model](#)
22. [Aggregate Model](#)
23. [Usage Notes](#)
24. [Data Distribution Concept](#)
25. [Manual partitioning](#)
26. [Dynamic Partitioning](#)
27. [Auto Partition](#)
28. [Data Bucketing](#)
29. [Common Issues](#)
30. [Basic concepts](#)
31. [Data Types](#)
32. [Column Compression](#)
33. [Index Overview](#)
34. [Sort Key and Prefix Index](#)
35. [Inverted Index](#)
36. [BloomFilter Index](#)
37. [N-Gram BloomFilter Index](#)
38. [Schema Change](#)

39. [Auto-Increment Column](#)
40. [Tiered Storage Overview](#)
41. [Tiered Storage of SSD and HDD](#)
42. [Remote Storage](#)
43. [Hybrid Row-Columnar Storage](#)
44. [Best Practices | Table Design](#)
45. [Loading Overview](#)
46. [local file](#)
47. [Kafka](#)
48. [Flink](#)
49. [HDFS | Data Source](#)
50. [Amazon S3](#)
51. [Google Cloud Storage | Data Source](#)
52. [Azure Storage](#)
53. [Alibaba Cloud OSS](#)
54. [Huawei Cloud OBS](#)
55. [Tencent Cloud COS](#)
56. [MinIO | Data Source](#)
57. [S3 Compatible Storage](#)
58. [Snowflake](#)
59. [BigQuery](#)
60. [Redshift](#)
61. [Migrating Data from Other OLAP](#)
62. [Migrating Data from Other OLTP](#)
63. [Stream Load](#)
64. [Broker Load](#)
65. [Routine Load](#)
66. [Insert Into Select](#)
67. [Insert Into Values](#)
68. [MySQL Load](#)
69. [Log Storage and Analysis | Doris Docs](#)
70. [CSV](#)
71. [JSON | File Format](#)
72. [Parquet | File Format](#)
73. [ORC | File Format](#)
74. [ARRAY | Complex Types](#)
75. [MAP | Complex Types](#)
76. [STRUCT | Complex Types](#)
77. [JSON | Complex Types](#)
78. [Bitmap](#)
79. [HLL](#)
80. [Variant](#)

81. [Handling Data Issues](#)
82. [Transforming Data During Load](#)
83. [Load High Availability](#)
84. [High Concurrency LOAD Optimization\(Group Commit\)](#)
85. [Load Best Practices](#)
86. [Data Update Overview](#)
87. [Updating Data with UPDATE Command](#)
88. [Updating Data on Unique Key Model](#)
89. [Updating Data on Aggregate Key Model](#)
90. [Concurrency Control for Updates in the Primary Key Model](#)
91. [Delete Overview](#)
92. [Deleting Data with DELETE Command](#)
93. [Batch Deletion Based on Load](#)
94. [Deleting Data with TRUNCATE Command](#)
95. [Replacing Atomic Table](#)
96. [Temporary Partition](#)
97. [Transaction](#)
98. [Export Overview](#)
99. [Export Manual | Export](#)
100. [SELECT INTO OUTFILE](#)
101. [Using MySQL Dump](#)
102. [Best Practices | Export](#)
103. [MySQL Compatibility](#)
104. [Join](#)
105. [Subquery](#)
106. [Multi-Dimensional Analytics](#)
107. [Window Function](#)
108. [Common Table Expression](#)
109. [Alias Function](#)
110. [Java UDF, UDAF, UDWF, UDTE](#)
111. [Complex Type](#)
112. [Column to Row \(Lateral View\)](#)
113. [Tuning Overview](#)
114. [Diagnostic Tools](#)
115. [Analysis Tools](#)
116. [Tuning Process](#)
117. [Materialized View Overview](#)
118. [Sync-Materialized View](#)
119. [Overview of Asynchronous Materialized Views](#)
120. [Creating, Querying, and Maintaining Asynchronous Materialized Views](#)
121. [Best Practices | Async Materialized View](#)
122. [Use Advice](#)

- 123. [FAQ](#)
- 124. [SQL Cache](#)
- 125. [High-Concurrency Point Query Optimization](#)
- 126. [BITMAP Precise Deduplication](#)
- 127. [HLL Approximate Deduplication](#)
- 128. [Colocation Join](#)
- 129. [Overview of Hints](#)
- 130. [Leading Hint](#)
- 131. [Distribute Hint](#)
- 132. [Optimizing Table Schema Design](#)
- 133. [Optimizing Table Index Design](#)
- 134. [Optimizing Table Scanning](#)
- 135. [Transparent Rewriting with Sync-Materialized View](#)
- 136. [Transparent Rewriting by Async-Materialized View](#)
- 137. [Optimizing Join with Colocate Group](#)
- 138. [Adjusting Join Shuffle Mode with Hint](#)
- 139. [Control CBO Rules With Hint](#)
- 140. [Reordering Join With Leading Hint](#)
- 141. [Accelerating Queries with SQL Cache](#)
- 142. [DML Tuning Plan](#)
- 143. [Adjustment of RuntimeFilter Wait Time](#)
- 144. [Data Skew Handling](#)
- 145. [Parallelism Tuning](#)
- 146. [Common Tuning Parameters](#)
- 147. [Query Optimizers](#)
- 148. [Parallel Execution](#)
- 149. [Runtime Filter](#)
- 150. [TOPN Query Optimization](#)
- 151. [Statistics | Optimization Technology Principle](#)
- 152. [Lakehouse Overview](#)
- 153. [Data Catalog Overview](#)
- 154. [Hive Catalog](#)
- 155. [Iceberg Catalog](#)
- 156. [Hudi Catalog](#)
- 157. [Paimon Catalog](#)
- 158. [MaxCompute Catalog](#)
- 159. [Delta Lake Catalog](#)
- 160. [BigQuery Catalog](#)
- 161. [Kudu Catalog](#)
- 162. [Elasticsearch Catalog](#)
- 163. [LakeSoul Catalog](#)
- 164. [JDBC Catalog](#)

165. [MySQL JDBC Catalog](#)
166. [PostgreSQL JDBC Catalog](#)
167. [Oracle JDBC Catalog](#)
168. [SQL Server JDBC Catalog](#)
169. [IBM Db2 JDBC Catalog](#)
170. [Clickhouse JDBC Catalog](#)
171. [SAP HANA JDBC Catalog](#)
172. [Oceanbase JDBC Catalog](#)
173. [Analyze Files on S3/HDFS](#)
174. [Hive Metastore](#)

Introduction to Apache Doris

What's Apache Doris

Apache Doris is an MPP-based real-time data warehouse known for its high query speed. For queries on large datasets, it returns results in sub-seconds. It supports both high-concurrency point queries and high-throughput complex analysis. It can be used for report analysis, ad-hoc queries, unified data warehouse, and data lake query acceleration. Based on Apache Doris, users can build applications for user behavior analysis, A/B testing platform, log analysis, user profile analysis, and e-commerce order analysis.

Apache Doris, formerly known as Palo, was initially created to support Baidu's ad reporting business. It was officially open-sourced in 2017 and donated by Baidu to the Apache Software Foundation in July 2018, where it was operated by members of the incubator project management committee under the guidance of Apache mentors. In June 2022, Apache Doris graduated from the Apache incubator as a Top-Level Project. By 2024, the Apache Doris community has gathered more than 600 contributors from hundreds of companies in different industries, with over 120 monthly active contributors.

Apache Doris has a wide user base. It has been used in production environments of over 5000 companies worldwide, including giants such as TikTok, Baidu, Tencent, and NetEase. It is also widely used across industries from finance, retailing, and telecommunications to energy, manufacturing, medical care, etc.

Usage Scenarios

As shown in the figure below, after various data integrations and processing, data sources are typically ingested into the real-time data warehouse Doris and offline lakehouses (such as Hive, Iceberg, and Hudi). These are widely used in OLAP analysis scenarios.

Apache Doris Usage Scenarios

Apache Doris is widely used in the following scenarios:

- **Real-time Data Analysis:**

- **Real-time Reporting and Decision-making:** Doris provides real-time updated reports and dashboards for both internal and external enterprise use, supporting real-time decision-making in automated processes.
- **Ad Hoc Analysis:** Doris offers multidimensional data analysis capabilities, enabling rapid business intelligence analysis and ad hoc queries to help users quickly uncover insights from complex data.
- **User Profiling and Behavior Analysis:** Doris can analyze user behaviors such as participation, retention, and conversion, while also supporting scenarios like population insights and crowd selection for behavior analysis.

- **Lakehouse Analytics:**

- **Lakehouse Query Acceleration:** Doris accelerates lakehouse data queries with its efficient query engine.
- **Federated Analytics:** Doris supports federated queries across multiple data sources, simplifying architecture and eliminating data silos.
- **Real-time Data Processing:** Doris combines real-time data streams and batch data processing capabilities to meet the needs of high concurrency and low-latency complex business requirements.

- **SQL-based Observability:**

- **Log and Event Analysis:** Doris enables real-time or batch analysis of logs and events in distributed systems, helping to identify issues and optimize performance.

Overall Architecture

Apache Doris uses the MySQL protocol, is highly compatible with MySQL syntax, and supports standard SQL. Users can access Apache Doris through various client tools, and it seamlessly integrates with BI tools.

Storage-Compute Integrated Architecture

The storage-compute integrated architecture of Apache Doris is streamlined and easy to maintain. As shown in the figure below, it consists of only two types of processes:

- **Frontend (FE):** Primarily responsible for handling user requests, query parsing and planning, metadata management, and node management tasks.
- **Backend (BE):** Primarily responsible for data storage and query execution. Data is partitioned into shards and stored with multiple replicas across BE nodes.

MPP architecture

In a production environment, multiple FE nodes can be deployed for disaster recovery. Each FE node maintains a full copy of the metadata. The FE nodes are divided into three roles:

Role	Function
Master	The FE Master node is responsible for metadata read and write operations. When metadata changes occur in the Master, they are synchronized to Follower or Observer nodes via the BDB JE protocol.
Follower	The Follower node is responsible for reading metadata. If the Master node fails, a Follower node can be selected as the new Master.
Observer	The Observer node is responsible for reading metadata and is mainly used to increase query concurrency. It does not participate in cluster leadership elections.

Both FE and BE processes are horizontally scalable, enabling a single cluster to support hundreds of machines and tens of petabytes of storage capacity. The FE and BE processes use a consistency protocol to ensure high availability of services and high reliability of data. The storage-compute integrated architecture is highly integrated, significantly reducing the operational complexity of distributed systems.

Core Features of Apache Doris

- **High Availability:** In Apache Doris, both metadata and data are stored with multiple replicas, synchronizing data logs via the quorum protocol. Data write is considered successful once a majority of replicas have completed the write, ensuring that the cluster remains available even if a few nodes fail. Apache Doris supports both same-city and cross-region disaster recovery, enabling dual-cluster master-slave modes. When some nodes experience failures, the cluster can automatically isolate the faulty nodes, preventing the overall cluster availability from being affected.
- **High Compatibility:** Apache Doris is highly compatible with the MySQL protocol and supports standard SQL syntax, covering most MySQL and Hive functions. This high compatibility allows users to seamlessly migrate and integrate existing applications and tools. Apache Doris supports the MySQL ecosystem, enabling users to connect Doris using MySQL Client tools for more convenient operations and maintenance. It also supports MySQL protocol compatibility for BI reporting tools and data transmission tools, ensuring efficiency and stability in data analysis and data transmission processes.
- **Real-Time Data Warehouse:** Based on Apache Doris, a real-time data warehouse service can be built. Apache Doris offers second-level data ingestion capabilities, capturing incremental changes from upstream online transactional databases into Doris within seconds. Leveraging vectorized engines, MPP architecture, and Pipeline execution engines, Doris provides sub-second data query capabilities, thereby constructing a high-performance, low-latency real-time data warehouse platform.
- **Unified Lakehouse:** Apache Doris can build a unified lakehouse architecture based on external data sources such as data lakes or relational databases. The Doris unified lakehouse solution enables seamless integration and free data flow between data lakes and data warehouses, helping users directly utilize data warehouse capabilities to solve data analysis problems in data lakes while fully leveraging data lake data management capabilities to enhance data value.
- **Flexible Modeling:** Apache Doris offers various modeling approaches, such as wide table models, pre-aggregation models, star/snowflake schemas, etc. During data import, data can be flattened into wide tables and written into Doris through compute engines like Flink or Spark, or data can be directly imported into Doris, performing data modeling operations through views, materialized views, or real-time multi-table joins.

Technical overview

Doris provides an efficient SQL interface and is fully compatible with the MySQL protocol. Its query engine is based on an MPP (Massively Parallel Processing) architecture, capable of efficiently executing complex analytical queries and achieving low-latency real-time queries. Through columnar storage technology for data encoding and compression, it significantly optimizes query performance and storage compression ratio.

Interface

Apache Doris adopts the MySQL protocol, supports standard SQL, and is highly compatible with MySQL syntax. Users can access Apache Doris through various client tools and seamlessly integrate it with BI tools, including but not limited to Smartbi, DataEase, FineBI, Tableau, Power BI, and Apache Superset. Apache Doris can work as the data source for any BI tools that support the MySQL protocol.

Storage engine

Apache Doris has a columnar storage engine, which encodes, compresses, and reads data by column. This enables a very high data compression ratio and largely reduces unnecessary data scanning, thus making more efficient use of IO and CPU resources.

Apache Doris supports various index structures to minimize data scans:

- **Sorted Compound Key Index:** Users can specify three columns at most to form a compound sort key. This can effectively prune data to better support highly concurrent reporting scenarios.
- **Min/Max Index:** This enables effective data filtering in equivalence and range queries of numeric types.
- **BloomFilter Index:** This is very effective in equivalence filtering and pruning of high-cardinality columns.
- **Inverted Index:** This enables fast searching for any field.

Apache Doris supports a variety of data models and has optimized them for different scenarios:

- **Detail Model (Duplicate Key Model):** A detail data model designed to meet the detailed storage requirements of fact tables.
- **Primary Key Model (Unique Key Model):** Ensures unique keys; data with the same key is overwritten, enabling row-level data updates.
- **Aggregate Model (Aggregate Key Model):** Merges value columns with the same key, significantly improving performance through pre-aggregation.

Apache Doris also supports strongly consistent single-table materialized views and asynchronously refreshed multi-table materialized views. Single-table materialized views are automatically refreshed and maintained by the system, requiring no manual intervention from users. Multi-table materialized views can be refreshed periodically using in-cluster scheduling or external scheduling tools, reducing the complexity of data modeling.

Query engine

Apache Doris has an MPP-based query engine for parallel execution between and within nodes. It supports distributed shuffle join for large tables to better handle complicated queries.

MPP-based Query engine 1

The query engine of Apache Doris is fully vectorized, with all memory structures laid out in a columnar format. This can largely reduce virtual function calls, increase cache hit rates, and make efficient use of SIMD instructions. Apache Doris delivers a 5~10 times higher performance in wide table aggregation scenarios than non-vectorized engines.

MPP-based Query engine 2

Apache Doris uses adaptive query execution technology to dynamically adjust the execution plan based on runtime statistics. For example, it can generate a runtime filter and push it to the probe side. Specifically, it pushes the filters to the lowest-level scan node on the probe side, which largely reduces the data amount to be processed and increases join performance. The runtime filter of Apache Doris supports In/Min/Max/Bloom Filter.

MPP-based pip_exec_3

Apache Doris uses a Pipeline execution engine that breaks down queries into multiple sub-tasks for parallel execution, fully leveraging multi-core CPU capabilities. It simultaneously addresses the thread explosion problem by limiting the number of query threads. The Pipeline execution engine reduces data copying and sharing, optimizes sorting and aggregation operations, thereby significantly improving query efficiency and throughput.

In terms of the optimizer, Apache Doris employs a combined optimization strategy of CBO (Cost-Based Optimizer), RBO (Rule-Based Optimizer), and HBO (History-Based Optimizer). RBO supports constant folding, subquery rewriting, predicate pushdown, and more. CBO supports join reordering and other optimizations. HBO recommends the optimal execution plan based on historical query information. These multiple optimization measures ensure that Doris can enumerate high-performance query plans across various types of queries.

Quick Start | GettingStarted

Quick Start

Warning:

The following rapid deployment methods are intended solely for local development and testing, and should not be used in production environments. The reasons are as follows:

1. **Data Vulnerability:** Data can be easily lost when using Docker deployment, as data is lost upon container destruction. Manual deployment of single-replica instances lacks data redundancy and backup capabilities, meaning machine failures could result in data loss.
2. **Single-Replica Configuration:** The table creation statements in the examples are all single-replica. In a production environment, multi-replica storage should be used to ensure data reliability.

Use Docker for Quick Deployment

Starting from Doris version 2.1.8, Docker can be used for rapid deployment.

Step 1: Download the Quick-Start script

[Download the script](#), run the following command to grant it the corresponding execution permissions.

```
chmod 755 start-doris.sh
```

Step 2: Start the cluster

Run the script to start the cluster, using the 2.1.9 version by default

```
bash start-doris.sh
```

You can specify the startup version through the -v parameter, such as:

```
bash start-doris.sh -v 2.1.8
```

Step 3: Connect to the cluster using MySQL client and check the cluster status

```
## Check the FE status to ensure that both the Join and Alive columns are true.
mysql -uroot -P9030 -h127.0.0.1 -e 'SELECT `host`, `join`, `alive` FROM frontends()'
+-----+-----+-----+
| host      | join | alive |
+-----+-----+-----+
```

```
| 127.0.0.1 | true | true |
+-----+-----+
## Check the BE status to ensure that the Alive column is true.
mysql -uroot -P9030 -h127.0.0.1 -e 'SELECT `host`, `alive` FROM backends()'
+-----+-----+
| host      | alive |
+-----+-----+
| 127.0.0.1 | 1     |
+-----+-----+
```

Local Quick Deployment

Environment Recommendations:

- **Operating System:** It is recommended to use AMD/ARM mainstream Linux environments such as CentOS 7.1 or Ubuntu 16.04 and above.
- **Java Environment:** It is advised to use the Java 8 runtime environment. For non-Oracle JDK commercial license users, please use the free Oracle JDK 8u300 or later versions.
- **User Permissions:** It is recommended to create a new Doris user on Linux and avoid using the root user for operations.

Step 1: Download the Binary Package

Download the corresponding binary installation package from the Apache Doris website [here](#), and extract it.

Step 2: Modify the Environment Variables

1. Modify the system's maximum open file descriptor limit

Use the following command to adjust the maximum file descriptor limit. After making this change, you need to restart the session to apply the configuration:

```
vi /etc/security/limits.conf
* soft nofile 1000000
* hard nofile 1000000
```

2. Modify Virtual Memory Area

Use the following command to permanently modify the virtual memory area to at least 2000000, and apply the change immediately:

```
cat >> /etc/sysctl.conf << EOF
vm.max_map_count = 2000000
EOF

## Take effect immediately
sysctl -p
```

Step 3: Install FE

1. Configure FE

Modify the following contents in the FE configuration file `apache-doris/fe/conf/fe.conf`:

```
## Specify Java environment
JAVA_HOME=/home/doris/jdk

## Specify the CIDR block for FE listening IP
priority_networks=127.0.0.1/32
```

2. Start FE

Run the FE process by executing the `start_fe.sh` script:

```
apache-doris/fe/bin/start_fe.sh --daemon
```

3. Check FE Status

Connect to the cluster using MySQL client and check the cluster status:

```
## Check FE Status to ensure that both the Join and Alive columns are true
mysql -uroot -P9030 -h127.0.0.1 -e "show frontends;"
```

Name	Host	EditLogPort	HttpPort	QueryPort	RpcPort	Role	IsMaster	ClusterId	Join	Alive	ReplayedJournalId	LastHeartbeat	IsHelper	ErrMsg	Version	CurrentConnected
fe_9d0169c5_b01f_478c_96ab_7c4e8602ec57	127.0.0.1	9010	8030	9030	9020	FOLLOWER	true	656872880	true	true	276	2024-07-28 18:07:39	true		doris-2.0.12-2971efd194	Yes

Step 4: Install BE

1. Configure BE

Modify the following contents in the BE configuration file `apache-doris/be/conf/be.conf`:

```
## Specify Java environment
JAVA_HOME=/home/doris/jdk

## Specify the CIDR block for BE's listening IP
priority_networks=127.0.0.1/32
```

2. Start BE

Start the BE process with the following command:

```
apache-doris/be/bin/start_be.sh --daemon
```

3. Register BE Node in the Cluster

Connect to the cluster using MySQL client:

```
mysql -uroot -P9030 -h127.0.0.1
```

Use the ADD BACKEND command to register the BE node:

```
ALTER SYSTEM ADD BACKEND "127.0.0.1:9050";
```

4. Check BE Status

Connect to the cluster using MySQL client and check the cluster status:

```
## Check BE Status to ensure that the Alive column is true
mysql -uroot -P9030 -h127.0.0.1 -e "show backends;"
```

BackendId	Host	HeartbeatPort	BePort	HttpPort	BrpcPort	LastStartTime	LastHeartbeat	Alive	SystemDecommissioned	TabletNum	DataUsedCapacity	TrashUsedCapacity	AvailCapacity	TotalCapacity	UsedPct	MaxDiskUsedPct	RemoteUsedCapacity	Tag	ErrMsg	Version	Status	HeartbeatFailureCounter	NodeRole
10156	127.0.0.1	9050	9060	8040	8060	2024-07-28 17:59:14	2024-07-28 18:08:24	true	false	14	0.000	0.000	8.342 GB	19.560 GB	57.35 %	57.35 %	0.000	{ "location" : "default" }		doris-2.0.12-2971efd194	{ "lastSuccessReportTabletsTime": "2024-07-28 18:08:14", "lastStreamLoadTime": -1, "isQueryDisabled": false, "isLoadDisabled": false }	0	mix

Run Queries

1. Connect to the cluster using MySQL client:

```
mysql -uroot -P9030 -h127.0.0.1
```

2. Create database and test table:

```

create database demo;

use demo;
create table mytable
(
    k1 TINYINT,
    k2 DECIMAL(10, 2) DEFAULT "10.05",
    k3 CHAR(10) COMMENT "string column",
    k4 INT NOT NULL DEFAULT "1" COMMENT "int column"
)
COMMENT "my first table"
DISTRIBUTED BY HASH(k1) BUCKETS 1
PROPERTIES (
    "replication_num" = "1"
);

```

3. Import test data:

Insert test data using the Insert Into statement

```

insert into mytable values
(1,0.14,'a1',20),
(2,1.04,'b2',21),
(3,3.14,'c3',22),
(4,4.35,'d4',23);

```

4. Execute the following SQL query in the MySQL client to view the imported data:

```

MySQL [demo]> select * from demo.mytable;
+-----+-----+-----+-----+
| k1   | k2   | k3   | k4   |
+-----+-----+-----+-----+
| 1    | 0.14 | a1   | 20   |
| 2    | 1.04 | b2   | 21   |
| 3    | 3.14 | c3   | 22   |
| 4    | 4.35 | d4   | 23   |
+-----+-----+-----+-----+
4 rows in set (0.10 sec)

```

Alternative to ClickHouse

Apache Doris and ClickHouse are both leading global real-time data warehouses, supporting columnar storage and fast queries. Doris has advantages like higher concurrency, more efficient joins, easier maintenance, and MySQL-like SQL syntax, making it simpler to use and deploy.

Featured Migration Cases

"Tencent Music's data platform has migrated from ClickHouse to Apache Doris, improving data timeliness and reducing maintenance costs. Doris' flexible ingestion methods and robust consistency protocol ensure high availability and reliability."

Highlight:

- Massive boost in multi-table join performance.
- Easy scaling and maintenance.
- Efficient data processing and real-time updates.

"Apache Doris has faster query response times than ClickHouse in the vast majority of scenarios, especially in complex join scenarios, where its performance is significantly superior to that of ClickHouse."

Highlight:

- Core business queries 2-3x.
- Complex join queries 2-10x.
- Can run all ClickHouse OOM queries.

"By replacing ClickHouse with Doris, Kwai successfully upgraded to a lakehouse architecture, simplifying the data pipeline and eliminating the need for data import, as Doris can directly access data lake data."

Highlight:

- Directly query of data lake data.
- Improved query performance.
- Flexible data governance with materialized views.

Apache Doris vs. ClickHouse

	Apache Doris	ClickHouse
Architecture & SQL	<ul style="list-style-type: none"> • Based on MPP architecture • Standard SQL support, MySQL-compatible 	<ul style="list-style-type: none"> • Uses Scatter-Gather architecture • SQL-like capabilities but with non-standard SQL
Queries	<ul style="list-style-type: none"> • Distributed joins • Cost-Based Optimization (CBO) • Query rewrites and multi-table materialized views • Higher concurrent performance 	<ul style="list-style-type: none"> • Poor join implementation • Lacks a Cost-Based Optimizer (CBO) • Only supports single-table materialized views • Lower concurrency performance
Real-time Updates	<ul style="list-style-type: none"> • Features a strongly consistent primary key storage model, supporting synchronous data updates and deletions 	<ul style="list-style-type: none"> • Only supports asynchronous updates, allowing old values to be read after an update.
Data API	<ul style="list-style-type: none"> • Offers high-throughput read APIs based on Arrow-flight, facilitating integration with other engines such as data science/AI tools 	<ul style="list-style-type: none"> • Only inefficient data reading via JDBC API
Building Open Lakehouse	<ul style="list-style-type: none"> • Serves as a Lakehouse SQL engine, supporting queries on Hive, Hudi, Iceberg, and Parquet data lake formats 	<ul style="list-style-type: none"> • Limited Lakehouse integration capabilities
Operations & Maintenance	<ul style="list-style-type: none"> • Supports automatic scaling in, scaling out, and replica balancing 	<ul style="list-style-type: none"> • Requires manual rebalancing during scaling operations
Performance	<ul style="list-style-type: none"> • In wide table benchmarks (ClickBench), Doris ranked top 1 or top 2 in October 2022 and October 2024, outperforming ClickHouse • In large TPC-H and TPC-DS tests, Doris achieved leading performance 	<ul style="list-style-type: none"> • In terms of ClickBench performance, ClickHouse and Doris have been taking turns leading • Experiences many OOM (Out of Memory) queries in large TPC-H and TPC-DS tests

Performance Comparison

ClickBench Benchmark

ClickBench is a benchmarking tool created and maintained by the ClickHouse team to evaluate the performance of analytical databases.

It focuses on testing the performance of **large, flat tables rather than complex multi-table joins**. It uses real-world data from a major web analytics platform, covering typical scenarios such as clickstream analysis and structured logs.

The benchmark consists of a set of queries that test aggregation operations and single-table performance, without involving complex joins. This makes it especially useful for evaluating databases optimized for real-time analytics and large-scale data processing.

SSB-Flat SF100 Benchmark

SSB-Flat SF100 is a benchmark designed to test the performance of analytical databases in handling large, wide tables.

It is derived from the Star Schema Benchmark (SSB) but flattens the star schema into a single wide table to **focus on the performance of single-table queries**.

The SF100 indicates that the data scale is 100 times the base size, making it a significant test for evaluating query performance and system scalability.

TPC-H SF100 Benchmark

The TPC-H benchmark with a scale factor of 100 (SF100) is a widely used standard for evaluating database performance. It includes a set of complex SQL queries designed to simulate real-world business intelligence workloads.

The SF100 indicates that the data size is 100 times the base size, making it a large-scale test to measure query performance and system scalability.

Note: Since ClickHouse failed to execute 7 queries, the total execution time refers to the time taken by Doris to run all 22 queries, and by ClickHouse to run only 15 queries.

TPC-DS 1TB Benchmark

TPC-DS 1TB is a widely recognized benchmark for evaluating the performance of data warehouses and analytical databases. It involves a dataset of approximately 1TB in size, containing around 6.35 billion records spread across 24 tables.

The benchmark includes 99 complex queries designed to test various aspects of database performance, such as joins, aggregations, and subqueries.

The TPC-DS schema is based on a snowflake schema, representing real-world scenarios like web, catalog, and store sales. The 1TB scale is considered a moderate size for data warehouses but is still challenging due to the complexity of the queries and the large number of records.

Note: TPC-DS makes heavy use of correlated subqueries which are at the time of testing (September 2024) not supported by ClickHouse. As a result, about 50% of benchmark queries will fail with errors.

More Migration Stories

- [Less components, higher performance: Apache Doris instead of ClickHouse, MySQL, Presto, and HBase](#)
- [Migrating from ClickHouse to Apache Doris: What happened?](#)
- [ClickHouse & Kudu to Doris: 10X concurrency increased, 70% latency down](#)

Alternative to Elasticsearch

Elasticsearch and Apache Doris are both popular in observability, cybersecurity, and real-time analytics. However, Elasticsearch can be costly in terms of storage and write resources. Apache Doris reduces these costs through efficient storage and high compression, and offers comprehensive analytical capabilities, such as JOIN and superior query performance.

Featured Migration Cases

"By replacing Elasticsearch with VeloDB(Powered by Apache Doris), GuanceDB showcases a big stride in improving data processing speed and reducing costs."

Highlight:

- 70% Cost Reduction
- 2-3x Faster full-text search performance
- Variant Data type is flexible to handle semi-structured data in log tracing

"Previously, we used multiple components for complex security analysis... Adopting Doris as a unified solution has significantly improved data writes, query performance and storage efficiency."

Highlight:

- 4x Faster write speeds
- 3x Better query performance
- 50% Storage space savings

"Compared to the original OLAP database, query performance has improved 5-10 times, concurrency has doubled, and analysis time has dropped from 10 minutes to under 1 minute for 90% of cases, all while using just one-third of the original resources."

Highlight:

- 2x Increasing report analysis concurrency
- 65% Storage space reduction
- Simplified query with standard SQL

Apache Doris vs. Elasticsearch

	Apache Doris	Elasticsearch
Open Source License	<ul style="list-style-type: none"> Licensed under Apache License 2.0 Stable License since governed by the Apache Software Foundation 	<ul style="list-style-type: none"> License changed from Apache License 2.0 to Elastic License, then to AGPL License Changing license since governed by Elastic NV
Architecture	<p>Higher flexibility and elasticity:</p> <ul style="list-style-type: none"> Strict workload isolation by workload group, powered by Linux CGroups, ideal for multi-tenancy Compute-Storage decoupled and coupled modes 	<p>Traditional deployment with limited elasticity:</p> <ul style="list-style-type: none"> Soft Workload Isolation by Thread Group Does not support decoupling compute and storage
Real-Time Data Writes	<ul style="list-style-type: none"> High throughput: Indexing only on one replica Pull-based ingestion via Kafka CDC, easier and simpler Support Logstash and Beats output plugin 	<ul style="list-style-type: none"> Low throughput: Indexing for multiple data replicas Requires additional tools like Logstash and Beats for pull-based ingestion, less convenient
Real-Time Data Storage	<ul style="list-style-type: none"> Low storage consumption with compression rates up to 1:5 - 1:10 Unique model supports both write and read optimization (MoW & MoR), retaining 90% of write speed when data is duplicated by key Aggregation model supports strong consistency, allows aggregated data updates, and coexists with original data Flexible Schema Change to meet dynamic business needs 	<ul style="list-style-type: none"> High storage consumption with a compression ratio of 1:1.5 Unique model only supports write optimization, with write performance loss up to 3 times The aggregation model does not allow aggregated data to be updated and does not coexist with the original data Limited support for Schema Change
Real-Time Data Queries	<ul style="list-style-type: none"> Lightning-Fast in various query workloads Supports multi-table JOINS and optimization for complex analysis Easy to use with standard SQL Open MySQL ecosystem 	<ul style="list-style-type: none"> Good at point queries, but not suited for data analysis No support for multi-table JOINS or complex analysis Difficult for users due to custom DSL Proprietary Elasticsearch ecosystem

Performance Comparison

Observability & Cyber Security

The [HTTP Logs](#) benchmark is an official Elasticsearch performance test designed for log storage and analysis. It uses a real-world HTTP log dataset to **evaluate indexing performance, storage efficiency, and query performance**.

This benchmark comprises 11 queries commonly used in log analysis scenarios, including keyword search, time range queries, aggregations, and sorting. As a result, it is highly suitable for assessing performance in observability and network security analysis contexts.

Real-Time Analytics

ClickBench is a benchmarking tool to evaluate the performance of analytical databases. It focuses on testing the performance of large, flat tables rather than complex multi-table joins. It uses real-world data from a major web analytics platform, covering typical scenarios such as clickstream analysis and structured logs.

The benchmark consists of a set of queries that test aggregation operations and single-table performance, without involving complex joins. This makes it especially useful for evaluating databases optimized for real-time analytics and large-scale data processing.

Note: These test results are archived benchmarks captured in December 2024. Current real-time comparisons are maintained at [ClickBench](#).

Apache Doris vs Trino / Presto

Apache Doris and Trino/Presto are both popular data lakehouse query engines, but Doris outperforms Trino/Presto in terms of performance. While Trino/Presto are primarily query engines, Doris can also function as a standalone data warehouse. This enables enterprises to unify their data warehouse and Lakehouse query engine into one with Doris, simplifying their data architecture

- **Unified:** Doris unifies data warehouse and Lakehouse query engine, simplifying the tech stack
- **10x Query Performance:** Doris native table boosts query performance by up to 10x compared to Presto/Trino
- **2-3x Faster:** Doris as a Lakehouse engine is 2-3x faster than Presto/Trino

Featured Migration Cases

World-Renowned
Internet Giant

“As the world-renowned internet giant, our early data platform used Trino, Pinot, Iceberg, and Kyuubi, but faced complexity, redundancy, and poor performance. By replacing them with Apache Doris, we unified its data lakehouse and query engine, **boosting performance and reducing costs by 30%.**”

“After switching from Presto to Doris, query performance significantly improved, **reducing query time from 20-40 seconds to 1-2 seconds.** By designing 2-3 materialized views based on common data dimensions, Doris can automatically match the optimal view for queries, further enhancing performance.”

“Using Trino and SparkSQL, query latency was at the minute level, and performance was low. **After switching to Doris, performance improved 2 times.** Doris also unified the tech stack, simplifying the management of real-time and interactive analytics tools.”

Apache Doris vs. Trino / Presto

	Apache Doris	Trino / Presto
Architecture	<ul style="list-style-type: none">• Unified Architecture: Combines the capabilities of a data warehouse and a Lakehouse query engine	<ul style="list-style-type: none">• Federated Querying: Excels in querying across multiple heterogeneous data sources without data movement, but lacks built-in storage
Execution Engine	<ul style="list-style-type: none">• Fully vectorized execution engine implemented in C++, for high-performance data processing	<ul style="list-style-type: none">• Implemented primarily in Java, with vectorization currently in development as part of the Hummingbird project
Query Optimizer	<ul style="list-style-type: none">• Advanced query optimizer with cost-based optimization for complex SQL operations like joins, aggregations, and sorting	<ul style="list-style-type: none">• Supports cost-based optimization but with less advanced statistics collection and manual full collection
Caching Mechanisms	<ul style="list-style-type: none">• Metadata Caching: In-memory metadata caching with TTL, auto-refresh, and incremental synchronization• Data Caching: Hot data caching on local SSDs for reduced network I/O• Query Caching: SQL Cache and Partition Cache for query result caching	<ul style="list-style-type: none">• Data Caching: Relies on external caching solutions like Alluxio
Materialized Views	<ul style="list-style-type: none">• Incremental Refresh: Supports incremental refresh and multiple update strategies• Transparent Acceleration: Query optimizer automatically routes queries to the most suitable materialized views	<ul style="list-style-type: none">• Manual Refresh: Limited to manual, full refresh with less advanced features
Use Cases	<ul style="list-style-type: none">• High-concurrency real-time analytics• Interactive analytics	<ul style="list-style-type: none">• Only Interactive analytics

Performance Comparison

TPC-DS 1TB Benchmark

The TPC-DS 1TB Benchmark evaluates data warehouse performance using a 1TB dataset with 6.35 billion records across 24 tables. It includes 99 complex queries to test joins, aggregations, and subqueries. Based on

a snowflake schema, it simulates real-world sales scenarios. The 1TB scale is challenging due to query complexity.

The test environment consists of:

- 1 FE/Coordinator node and 5 BE/Worker nodes.
- Each node has 64 cores, 1.5TB of memory, and SSD storage.
- HDFS is co-located on these nodes, and Hive tables are created.

In this test, using the same dataset and equal computing service, the results shows that:

- **When data is imported into Doris' internal tables and queried using Doris, it achieves the shortest execution time.**
- **When Doris and Trino are used separately to query data directly from Hive tables, Doris demonstrates superior query acceleration performance in the data lake.**

Environment Checking

When deploying Doris, the following checks need to be performed for the hardware and software environment:

- Hardware Environment Check
- Recommended Server Configuration
- Disk Space Calculation
- Java Environment Check

Hardware Environment Check

During the hardware environment check, the following hardware conditions should be examined:

Check Item	Expected Result
CPU	Should support AVX2 instruction set.
Memory	Recommended at least 4 times the CPU size.
Storage	SSD recommended.
File System	ext4 or xfs file system.
Network Card	10 Gigabit network card.

CPU Check

When installing Doris, it is recommended to choose a machine that supports the AVX2 instruction set to leverage the vectorization capabilities of AVX2 for query acceleration.

Run the following command to check if the machine supports the AVX2 instruction set:

```
cat /proc/cpuinfo | grep avx2
```

If the machine does not support the AVX2 instruction set, you can use the no AVX2 Doris installation package for deployment.

Memory Check

Doris does not have strict memory limits. Generally, for production environments, you can choose the memory size based on the following recommendations:

Component	Recommended Memory Configuration
FE	At least 16GB recommended.

Component	Recommended Memory Configuration
BE	Memory should be at least 4 times the number of CPU cores (for example, for a 16-core machine, at least 64GB memory is recommended). Better performance can be achieved with memory 8 times the number of CPU cores.

Storage Check

Doris allows data to be stored on SSD, HDD, or object storage during deployment.

SSD is recommended for data storage in the following scenarios:

- High-concurrency point query scenarios with large-scale data
- High-frequency data update scenarios with large-scale data

File System Check

Doris recommends using EXT4 or XFS file systems:

- **EXT4:** The EXT4 file system offers good stability, performance, and lower fragmentation issues.
- **XFS:** The XFS file system performs excellently in handling large-scale data and high-concurrency write operations, making it suitable for high-throughput applications.

Network Card Check

Doris involves distributing data partitions across different instances for parallel processing, which results in some network resource overhead. To optimize Doris performance and reduce network resource overhead, it is strongly recommended to use a 10 Gigabit Ethernet (10GbE) or faster network during deployment. If multiple network cards are available, it is recommended to use link aggregation to combine multiple network cards into one virtual interface, which improves network bandwidth, redundancy, and complex balancing capabilities.

Server Configuration Recommendations

Doris can be deployed on x86-64 or ARM64 architecture server platforms.

• Development and Testing Environments

In development and testing environments, FE and BE instances can be deployed in a mixed manner, following these guidelines:

- In a validation testing environment, one FE and one BE can be deployed on a single server, but it is not recommended to deploy multiple FE and BE instances on the same machine.
- If 3 replicas of data are required, at least 3 servers are needed, with each server deploying one BE instance.

Module	CPU	Memory	Disk	Network	Minimum Instance Count
Frontend	8 cores +	8 GB+	SSD or SATA, 10 GB+	Gigabit/Ten-Gigabit	1

Module	CPU	Memory	Disk	Network	Minimum Instance Count
Backend	8 cores +	16 GB+	SSD or SATA, 50 GB+	Gigabit/Ten-Gigabit	1

• Production Environments

In a production environment, it is recommended to deploy FE and BE instances independently, following these guidelines:

- If resources are limited and FE and BE need to be co-located on the same server, it is advised to store FE and BE data on separate hard drives.
- BE nodes can be configured with multiple hard drives, allowing a single BE instance to utilize multiple HDD or SSD disks.

Recommended server specifications are as follows:

Module	CPU	Memory	Disk	Network	Minimum Instance Count
Frontend	16 cores +	64 GB+	SSD or RAID card, 100 GB+	10-Gigabit	1
Backend	16 cores +	64 GB+	SSD or SATA, 100 GB+	10-Gigabit	3

Disk Space Calculation

In the Doris cluster, FE (Frontend) is mainly used for metadata storage, including metadata edit logs and images. BE (Backend) disk space is primarily used for storing data, and it needs to be calculated based on business requirements. | Component | Disk Space Description | | ——— |

————— | FE | It is recommended to reserve more than 100 GB of storage space, using SSD disks. | BE | Doris uses LZ4 compression by default. The compression ratio is around 0.3 - 0.5. Disk space should be calculated as total data volume * 3 (for 3 replicas), and 40% of the space should be reserved for backend compaction and temporary data storage. |

Java Environment Check

All Doris processes depend on Java:

- **For versions before 2.1 (inclusive):** please use Java 8, recommended version: jdk-8u352 or later.
- **For versions from 3.0 (inclusive) onwards:** please use Java 17, recommended version: jdk-17.0.10 or later.

Cluster Planning

Port Planning

Doris instances communicate over the network, and their proper functioning requires the following ports to be available. Administrators can adjust Doris' port configuration based on the actual environment:

Instance Name	Port Name	Default Port	Communication Direction	Description
BE	be_port	9060	FE -> BE	Thrift Server port on BE, used to receive requests from FE
BE	webserver_port	8040	BE <-> BE	HTTP Server port on BE
BE	heartbeat_service_port	9050	FE -> BE	Heartbeat service port (Thrift) on BE, used to receive heartbeats from FE
BE	brpc_port	8060	FE <-> BE, BE <-> BE	BRPC port on BE, used for communication between BEs
FE	http_port	8030	FE <-> FE, Client <-> FE	HTTP Server port on FE
FE	rpc_port	9020	BE -> FE, FE <-> FE	Thrift Server port on FE, each FE should have the same configuration
FE	query_port	9030	Client <-> FE	MySQL Server port on FE
FE	edit_log_port	9010	FE <-> FE	bdbje communication port on FE

Node Count Planning

FE Node Count

FE nodes are primarily responsible for user request handling, query parsing and planning, metadata management, and node management.

For production clusters, it is generally recommended to deploy at least 3 FE nodes to achieve a high-availability environment. FE nodes are divided into the following two roles:

- **Follower nodes:** Participate in election operations. When the Master node fails, a Follower node will be selected as the new Master.
- **Observer nodes:** Only sync metadata from the Leader node and do not participate in the election. These nodes can be used for horizontal scaling to improve the read service capacity of metadata.

In general, it is recommended to deploy at least 3 Follower nodes. In high-concurrency scenarios, increasing the number of Observer nodes can help improve the cluster's connection capacity.

BE Node Count

BE nodes are responsible for data storage and computation. In production environments, to ensure data reliability and fault tolerance, 3 copies of data are usually stored. Therefore, it is recommended to deploy at least 3 BE nodes.

BE nodes support horizontal scaling, and by increasing the number of BE nodes, the query performance and concurrent processing capabilities of the cluster can be effectively improved.

OS Checking

When deploying Doris, ensure the following operating system configurations:

- Disable the swap partition
- Disable transparent huge pages
- Ensure the system has enough virtual memory space
- Disable CPU power-saving mode
- Ensure new network connections are reset on overflow
- Ensure Doris-related ports are open or the firewall is disabled
- Ensure the system allows a sufficient number of open file descriptors
- Install and configure NTP service for clock synchronization

Disable Swap Partition

It is recommended to disable the swap partition when deploying Doris. The kernel may move memory data to the swap area when it detects memory pressure, but this can negatively impact Doris performance due to the kernel's limited understanding of application behavior.

To disable swap temporarily (swap will be re-enabled after a restart):

```
swapoff -a
```

To permanently disable swap, edit `/etc/fstab` and comment out the swap partition entry, then restart the machine:

```
# /etc/fstab
# <file system>      <dir>      <type>      <options>      <dump> <pass>
tmpfs                /tmp        tmpfs        nodev,nosuid    0        0
/dev/sda1            /           ext4         defaults,noatime 0        1
# /dev/sda2           none        swap         defaults         0        0
/dev/sda3            /home       ext4         defaults,noatime 0        2
```

Disable Transparent Huge Pages

In high-load, low-latency scenarios, disabling Transparent Huge Pages (THP) is recommended to avoid performance degradation and memory fragmentation, ensuring stable memory usage for Doris.

Use the following commands to disable THP temporarily:

```
echo madvise > /sys/kernel/mm/transparent_hugepage/enabled
echo madvise > /sys/kernel/mm/transparent_hugepage/defrag
```

To permanently disable THP, add the following commands to `/etc/rc.d/rc.local` to ensure it takes effect after a restart:

```
cat >> /etc/rc.d/rc.local << EOF
echo madvise > /sys/kernel/mm/transparent_hugepage/enabled
echo madvise > /sys/kernel/mm/transparent_hugepage/defrag
EOF
chmod +x /etc/rc.d/rc.local
```

Ensure Sufficient Virtual Memory Area

To allow Doris to handle large datasets, the system must have enough virtual memory space. Without adequate memory mapping, Doris may encounter errors like Too many open files during startup or runtime.

You can permanently modify the virtual memory area to at least 2000000 with the following command, and it will take effect immediately:

```
cat >> /etc/sysctl.conf << EOF
vm.max_map_count = 2000000
EOF

# Take effect immediately
sysctl -p
```

Disable CPU Power-Saving Mode

Disabling CPU power-saving mode ensures stable high performance during high load, preventing fluctuations and delays caused by reduced CPU frequency.

Use the following command to set the CPU governor to “performance,” disabling power-saving modes:

```
echo 'performance' | sudo tee /sys/devices/system/cpu/cpu*/cpufreq/scaling_governor
```

Reset New Connections on Network Overflow

Ensure that when TCP connection buffers overflow, new connections are reset immediately. This prevents buffer blocking during high load and improves responsiveness and stability.

You can permanently configure the system to automatically reset new connections with the following commands, and it will take effect immediately:

```
cat >> /etc/sysctl.conf << EOF
net.ipv4.tcp_abort_on_overflow=1
EOF

# Take effect immediately
sysctl -p
```

Open Doris-related Ports

If Doris-related ports are blocked, you can try disabling the firewall to verify whether it is the cause. If the firewall is the issue, open the relevant ports for Doris components.

```
sudo systemctl stop firewalld.service
sudo systemctl disable firewalld.service
```

Increase System's Open File Descriptors Limit

Since Doris manages a large number of files, you need to increase the system's file descriptor limit.

To change the maximum number of open files, add the following to `/etc/security/limits.conf`:

```
vi /etc/security/limits.conf
* soft nfile 1000000
* hard nfile 1000000
```

Ensure NTP Service is Installed on Cluster Deployment Machines

Doris requires the metadata's timestamp accuracy to be within 5000ms. To ensure consistent time across all nodes in the cluster and avoid metadata inconsistencies, you need to synchronize clocks across all machines using the NTP service.

Use the following commands to start and enable the NTP service:

```
sudo systemctl start ntpd.service
sudo systemctl enable ntpd.service
```

Deploy Integrated Storage Compute Cluster Manually

After completing the preliminary checks and planning, such as environment checks, cluster planning, and operating system inspections, you can begin deploying the cluster.

The integrated storage-compute architecture is shown below, and the deployment of the integrated storage-compute cluster involves four steps:

[integrated-storage-compute-architecture](#)

1. **Deploy FE Master Node:** Deploy the first FE node as the Master node;
2. **Deploy FE Cluster:** Deploy the FE cluster by adding Follower or Observer FE nodes;
3. **Deploy BE Nodes:** Register BE nodes to the FE cluster;
4. **Verify Cluster Correctness:** After deployment, connect to and verify the cluster's correctness.

Step 1: Deploy FE Master Node

1. Create Metadata Path

When deploying FE, it is recommended to store metadata on a different hard drive from the BE node data storage.

When extracting the installation package, a `doris-meta` directory is included by default. It is recommended to create a separate metadata directory and link it to the `doris-meta` directory. In production, it's highly advised to use a separate directory outside the Doris installation folder, preferably on an SSD. For testing and development environments, you can use the default configuration.

```
## Use a separate disk for FE metadata
mkdir -p <doris_meta_created>

## Create FE metadata directory symlink
ln -s <doris_meta_created> <doris_meta_original>
```

2. Modify FE Configuration File

The FE configuration file is located in the `conf` directory under the FE deployment path. Before starting the FE node, modify the `conf/fe.conf` file..

Before deploying the FE node, it is recommended to modify the following configurations:

```
## modify Java Heap
JAVA_OPTS="-Xmx16384m -XX:+UseMembar -XX:SurvivorRatio=8 -XX:MaxTenuringThreshold=7 -
XX:+PrintGCDateStamps -XX:+PrintGCDetails -XX:+UseConcMarkSweepGC -XX:+UseParNewGC -
XX:+CMSClassUnloadingEnabled -XX:-CMSParallelRemarkEnabled -XX:CMSInitiatingOccupancyFraction=80 -
XX:SoftRefLRUPolicyMSPerMB=0 -Xloggc:$DORIS_HOME/log/fe.gc.log.$DATE"
```

```
## modify case sensitivity
lower_case_table_names = 1

## modify network CIDR
priority_networks = 10.1.3.0/24

## modify Java Home
JAVA_HOME = <your-java-home-path>
```

Parameter Descriptions: For more details, refer to the [FE Configuration](#):

Parameter	Suggestion
JAVA_OPTS	Specify the <code>-Xmx</code> parameter to adjust the Java Heap. It is recommended to set it to above 16G in production environments.
lower_case_table_names	Set case sensitivity. It is recommended to adjust it to 1, meaning case-insensitive.
priority_networks	Network CIDR is specified based on the network IP address. It can be ignored in an FQDN environment.
JAVA_HOME	It is recommended to use a JDK environment independent of the operating system for Doris.

3. Start FE Process

You can start the FE process using the following command:

```
bin/start_fe.sh --daemon
```

The FE process will start and run in the background. By default, logs are stored in the `log/` directory. If the startup fails, you can check the `log/fe.log` or `log/fe.out` files for error details.

4. Check FE Startup Status

You can connect to the Doris cluster using MySQL Client. The default user is `root`, and the password is empty.

```
mysql -uroot -P<fe_query_port> -h<fe_ip_address>
```

After connecting to the Doris cluster, you can use the `show frontends` command to check the status of FE nodes. Typically, you should verify the following:

- **Alive:** If true, it indicates the node is alive.
- **Join:** If true, it indicates the node has joined the cluster, but it doesn't necessarily mean the node is still active in the cluster (it may have lost connection).
- **IsMaster:** If true, it indicates the current node is the Master node.

Step 2: Deploy FE Cluster (Optional)

In production, it is recommended to deploy at least 3 nodes. After deploying the FE Master node, you should deploy two additional FE Follower nodes.

1. Create Metadata Directory

Follow the same steps as for deploying the FE Master node to create the `doris-meta` directory.

2. Modify FE Follower Node Configuration

Modify the FE configuration file for the Follower node, following the same steps as for the FE Master node. Typically, you can simply copy the configuration file from the FE Master node.

3. Register New FE Follower Node in the Doris Cluster

Before starting a new FE node, you need to register the new FE node in the FE cluster.

```
## connect a alive FE node
mysql -uroot -P<fe_query_port> -h<fe_ip_address>

## register a new FE follower node
ALTER SYSTEM ADD FOLLOWER "<fe_ip_address>:<fe_edit_log_port>"
```

To add an observer node, use the `ADD OBSERVER` command:

```
## register a new FE observer node
ALTER SYSTEM ADD OBSERVER "<fe_ip_address>:<fe_edit_log_port>"
```

:::caution Note

- The number of FE Follower nodes (including Master) should be odd. It is recommended to deploy 3 nodes for high availability.
- When FE is deployed in high availability mode (1 Master, 2 Followers), we recommend adding Observer FE nodes to extend the FE read service capacity. :::

4. Start FE Follower Node

The FE Follower node can be started with the following command, which will automatically synchronize metadata.

```
bin/start_fe.sh --helper <helper_fe_ip>:<fe_edit_log_port> --daemon
```

Here, `helper_fe_ip` refers to any live node in the FE cluster. The `--helper` parameter is used only during the initial startup of FE to synchronize metadata; subsequent restarts do not require this parameter.

5. Check Follower Node Status

The method for checking the FE Follower node status is the same as for the FE Master node status. After adding the Follower node, use the `show frontends` command to check the FE node status. Unlike the Master, `thlsMaster` state should be false.

Step 3: Deploy BE Node

1. Create Data Directory

The BE process is responsible for data computation and storage. The data directory is by default located under `be/storage`. In a production environment, it is common to store BE data on a separate disk, placing the BE data and deployment files on different disks. BE supports distributing data across multiple disks to better utilize the I/O capabilities of multiple hard drives.

```
## Create a BE data storage directory on each data disk
mkdir -p <be_storage_root_path>
```

2. Modify BE Configuration File

The BE configuration file is located in the `conf` directory under the BE deployment path. Before starting the BE node, you need to modify the `conf/be.conf` file.

```
## modify storage path for BE node
storage_root_path=/home/disk1/doris,medium:HDD;/home/disk2/doris,medium:SSD

## modify network CIDR
priority_networks = 10.1.3.0/24

## modify Java Home in be/conf/be.conf
JAVA_HOME = <your-java-home-path>
```

Parameter explanations are as follows:

Parameters	Suggestions
priority_networks	Network CIDR, specified by network IP address. Can be ignored in FQDN environments.
JAVA_OPTS	Set the <code>-Xmx</code> parameter to adjust the Java heap size. It is recommended to set it to 2GB or more for production environments.
JAVA_HOME	It is recommended to use a JDK environment that is independent of the operating system for Doris.

3. Register BE Node in Doris

Before starting the BE node, register it in the FE cluster:

```
## connect a alive FE node
mysql -uroot -P<fe_query_port> -h<fe_ip_address>

## Register BE node
ALTER SYSTEM ADD BACKEND "<be_ip_address>:<be_heartbeat_service_port>"
```

4. Start BE Process

The BE process can be started with the following command:

```
bin/start_be.sh --daemon
```

The BE process starts and runs in the background. Logs are stored by default in the `log/` directory. If the startup fails, check the `log/be.log` or `log/be.out` files for error information.

5. Check BE Startup Status

After connecting to the Doris cluster, use the `show backends` command to check the BE node status.

```
## connect a alive FE node
mysql -uroot -P<fe_query_port> -h<fe_ip_address>

## check BE node status
show backends;
```

Typically, pay attention to the following states:

- `Alive` being `true` indicates that the node is alive.
- `TabletNum` represents the number of shards on the node. Newly added nodes will undergo data balancing, and the `TabletNum` will gradually become more evenly distributed.

Step 4: Verify Cluster Integrity

1. Log in to the Database

Log in to the Doris cluster using the MySQL Client.

```
## connect a alive fe node
mysql -uroot -P<fe_query_port> -h<fe_ip_address>
```

2. Check Doris Installation Information

Use `show frontends` and `show backends` to view the status of each database instance.

```
-- check fe status
show frontends \G

-- check be status
show backends \G
```

3. Change Doris Cluster Password

When the Doris cluster is created, a user named `root` is automatically created, and its password is set to empty by default. For security reasons, it is recommended to set a new password for the `root` user immediately after the cluster is created.

```
-- check the current user
select user();
+-----+
| user() |
+-----+
```

```
| 'root'@'192.168.88.30' |
+-----+

-- modify the password for current user
SET PASSWORD = PASSWORD('doris_new_passwd');
```

4. Create a Test Table and Insert Data

To verify the integrity of the cluster, you can create a test table in the newly created cluster and insert some data.

```
-- create a test database
create database testdb;

-- create a test table
CREATE TABLE testdb.table_hash
(
    k1 TINYINT,
    k2 DECIMAL(10, 2) DEFAULT "10.5",
    k3 VARCHAR(10) COMMENT "string column",
    k4 INT NOT NULL DEFAULT "1" COMMENT "int column"
)
COMMENT "my first table"
DISTRIBUTED BY HASH(k1) BUCKETS 32;
```

Doris is compatible with the MySQL protocol, and you can use the INSERT statement to insert data.

```
-- insert data
INSERT INTO testdb.table_hash VALUES
(1, 10.1, 'AAA', 10),
(2, 10.2, 'BBB', 20),
(3, 10.3, 'CCC', 30),
(4, 10.4, 'DDD', 40),
(5, 10.5, 'EEE', 50);

-- check the data
SELECT * from testdb.table_hash;
```

k1	k2	k3	k4
3	10.30	CCC	30
4	10.40	DDD	40
5	10.50	EEE	50
1	10.10	AAA	10
2	10.20	BBB	20

Deploy Doris Operator

Deploying the Doris Operator involves three steps: install the CustomResourceDefinitions, deploy the Operator service, verify the deployment status.

Step 1: Install CustomResourceDefinitions

Add the custom resource (CRD) of Doris Operator using the following command:

```
kubectl create -f https://raw.githubusercontent.com/apache/doris-operator/master/config/crd/bases/crds.yaml
```

Step 2: Install Doris Operator and RBAC rules

Install Doris Operator using the following command:

```
kubectl apply -f https://raw.githubusercontent.com/apache/doris-operator/master/config/operator/operator.yaml
```

Expected output:

```
namespace/doris created
role.rbac.authorization.k8s.io/leader-election-role created
rolebinding.rbac.authorization.k8s.io/leader-election-rolebinding created
clusterrole.rbac.authorization.k8s.io/doris-operator created
clusterrolebinding.rbac.authorization.k8s.io/doris-operator-rolebinding created
serviceaccount/doris-operator created
deployment.apps/doris-operator created
```

Step 3: Verify Doris Operator status

Check the deployment status of Doris Operator using the following command:

```
kubectl get pods -n doris
```

Expected output:

NAME	READY	STATUS	RESTARTS	AGE
doris-operator-7f578c86cb-nz6jn	1/1	Running	0	19m

Config Doris to Deploy

Cluster planning

In the default DorisCluster resource deployment, the FE and BE images may not be the latest versions, and the default replica count for both FE and BE is set to 3. Additionally, the default resource configuration for FE is 6 CPUs and 12Gi of memory, while for BE, it is 8 CPUs and 16Gi of memory. This section describes how to modify these default configurations according to your requirements.

Image configuration

Doris Operator is decoupled from the Doris version and supports deploying Doris versions 2.0 and above.

FE image configuration

To specify the FE image version, use the following configuration:

```
spec:
  feSpec:
    image: ${image}
```

Replace `${image}` with the desired image name, then update the configuration in the target [DorisCluster resource](#). Official FE images are available at [FE Image](#).

BE image configuration

To specify the BE image version, use the following configuration:

```
spec:
  beSpec:
    image: ${image}
```

Replace `${image}` with the desired image name, then update the configuration in the target [DorisCluster resource](#). Official BE images are available at [BE Image](#).

Replicas configuration

FE Replicas configuration

To modify the default FE replica count of 3 to 5, use the following configuration:

```
spec:
  feSpec:
    replicas: 5
```

Update the configuration in the target [DorisCluster resource](#).

BE replicas configuration

To modify the default FE replica count of 3 to 5, use the following configuration:

```
spec:
  beSpec:
    replicas: 5
```

Update the configuration to the [DorisCluster resource](#) that needs to be deployed.

Computing resource configuration

FE computing resource configuration

The default compute resource configuration for FE is 6 CPUs and 12Gi of memory. To modify it to 8 CPUs and 16Gi, use the following configuration:

```
spec:
  feSpec:
    requests:
      cpu: 8
      memory: 16Gi
    limits:
      cpu: 8
      memory: 16Gi
```

Update the configuration in the target [DorisCluster resource](#).

BE computing resource configuration

The default compute resource configuration for BE is 8 CPUs and 16Gi of memory. To modify it to 16 CPUs and 32Gi of memory, use the following configuration:

```
spec:
  beSpec:
    requests:
      cpu: 16
      memory: 32Gi
    limits:
      cpu: 16
      memory: 32Gi
```

Update the configuration in the target [DorisCluster resource](#).

Tip

The minimum required resources for FE and BE to start are 4 CPUs and 8Gi of memory. For normal performance testing, it is recommended to configure 8 CPUs and 8Gi of memory.

Custom startup configuration

Doris uses ConfigMap to decouple configuration files from services, in Kubernetes. By default, services use the default configurations in the image as startup parameter configurations. To customize the startup parameters, create a specific ConfigMap following the instructions in the [FE Configuration Document](#) and the [BE Configuration Document](#). Then deploy the customized ConfigMap to the namespace where the [DorisCluster resource](#) is to be deployed.

Custom FE startup configuration

Step 1: Create and deploy the FE ConfigMap

The following example defines a ConfigMap named fe-conf for use with Doris FE:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: fe-conf
  labels:
    app.kubernetes.io/component: fe
data:
  fe.conf: |
    CUR_DATE=`date +%Y%m%d-%H%M%S`
    # the output dir of stderr and stdout
    LOG_DIR = ${DORIS_HOME}/log
    JAVA_OPTS="-Djavax.security.auth.useSubjectCredsOnly=false -Xss4m -Xmx8192m -XX:+UseMembar -
    XX:SurvivorRatio=8 -XX:MaxTenuringThreshold=7 -XX:+PrintGCDateStamps -XX:+PrintGCDetails -
    XX:+UseConcMarkSweepGC -XX:+UseParNewGC -XX:+CMSClassUnloadingEnabled -XX:-CMSParallelRemarkEnabled -
    XX:CMSInitiatingOccupancyFraction=80 -XX:SoftRefLRUPolicyMSPerMB=0 -
    Xloggc:${DORIS_HOME}/log/fe.gc.log.${CUR_DATE}"
    # For jdk 9+, this JAVA_OPTS will be used as default JVM options
    JAVA_OPTS_FOR_JDK_9="-Djavax.security.auth.useSubjectCredsOnly=false -Xss4m -Xmx8192m -XX:SurvivorRatio=8
    -XX:MaxTenuringThreshold=7 -XX:+CMSClassUnloadingEnabled -XX:-CMSParallelRemarkEnabled -
    XX:CMSInitiatingOccupancyFraction=80 -XX:SoftRefLRUPolicyMSPerMB=0 -
    Xloggc*:${DORIS_HOME}/log/fe.gc.log.${CUR_DATE}:time"
    # INFO, WARN, ERROR, FATAL
    sys_log_level = INFO
    # NORMAL, BRIEF, ASYNC
    sys_log_mode = NORMAL
    # Default dirs to put jdbc drivers,default value is ${DORIS_HOME}/jdbc_drivers
    # jdbc_drivers_dir = ${DORIS_HOME}/jdbc_drivers
    http_port = 8030
    rpc_port = 9020
    query_port = 9030
    edit_log_port = 9010
    enable_fqdn_mode = true
```

When using the ConfigMap to mount FE startup configuration, the key corresponding to the configuration must be fe.conf. Write the ConfigMap to a file and deploy it to the namespace where the DorisCluster resource is deployed, using the following command:

```
kubectl -n ${namespace} apply -f ${feConfigMapFile}.yaml
```

Here, \${namespace} refers to the namespace where the DorisCluster is to be deployed, and \${feConfigMapFile} is the name of the ConfigMap file for FE.

step 2: Update the DorisCluster resource

To use the ConfigMap named fe-conf for mounting the startup configuration, add the following config to the FE spec of the [DorisCluster resource](#):

```
spec:
  feSpec:
    configMapInfo:
```

```
configMapName: fe-conf
resolveKey: fe.conf
```

Tip

Please ensure that `enable_fqdn_mode=true` is included in the startup configuration.. If you want to use IP mode and K8s have the ability that the pod IP keep the same after restarted, please refer to the issue [#138](#) to config.

Custom BE startup configuration

Step 1: Create and deploy the BE ConfigMap

The following example defines a ConfigMap named `be-conf` for use with Doris BE:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: be-conf
  labels:
    app.kubernetes.io/component: be
data:
  be.conf: |
    CUR_DATE=`date +%Y%m%d-%H%M%S`

    PPROF_TMPDIR="$DORIS_HOME/log/"

    JAVA_OPTS="-Xmx1024m -DlogPath=$DORIS_HOME/log/jni.log -Xloggc:$DORIS_HOME/log/be.gc.log.$CUR_DATE -
Djavax.security.auth.useSubjectCredsOnly=false -Dsun.java.command=DorisBE -XX:-CriticalJNINatives -
DJDBC_MIN_POOL=1 -DJDBC_MAX_POOL=100 -DJDBC_MAX_IDLE_TIME=300000 -DJDBC_MAX_WAIT_TIME=5000"

    # For jdk 9+, this JAVA_OPTS will be used as default JVM options
    JAVA_OPTS_FOR_JDK_9="-Xmx1024m -DlogPath=$DORIS_HOME/log/jni.log -
Xloggc:$DORIS_HOME/log/be.gc.log.$CUR_DATE -Djavax.security.auth.useSubjectCredsOnly=false -
Dsun.java.command=DorisBE -XX:-CriticalJNINatives -DJDBC_MIN_POOL=1 -DJDBC_MAX_POOL=100 -
DJDBC_MAX_IDLE_TIME=300000 -DJDBC_MAX_WAIT_TIME=5000"

    # since 1.2, the JAVA_HOME need to be set to run BE process.
    # JAVA_HOME=/path/to/jdk/

    # https://doris.apache.org/community/developer-guide/debug-tool#jemalloc-heap-profile
    # https://jemalloc.net/jemalloc.3.html

    JEMALLOC_CONF="percpu_arena:percpu,background_thread:true,metadata_thp:auto,muzzy_decay_ms:15000,dirty_decay_
ms:15000,oversize_threshold:0,lg_tcache_max:20,prof:false,lg_prof_interval:32,lg_prof_sample:19,prof_gdump:fa
lse,prof_accum:false,prof_leak:false,prof_final:false"
    JEMALLOC_PROF_PREFIX=""

    # INFO, WARNING, ERROR, FATAL
    sys_log_level = INFO

    # ports for admin, web, heartbeat service
    be_port = 9060
    webserver_port = 8040
    heartbeat_service_port = 9050
    brpc_port = 8060
```

When using the ConfigMap to mount BE startup configuration, the key corresponding to the configuration must be `be.conf`. Write the ConfigMap to a file and deploy it to the namespace where the [DorisCluster resource](#) is deployed using the following command:

```
kubectl -n ${namespace} apply -f ${beConfigMapFile}.yaml
```

Here, `${namespace}` refers to the namespace where the DorisCluster resource needs to be deployed, and `${beConfigMapFile}` is the name of the ConfigMap file for BE.

step 2: Update the DorisCluster resource

To use the ConfigMap named `be-conf` for mounting the startup configuration, add the following config to the BE spec of the [DorisCluster resource](#):

```
spec:
  feSpec:
    configMapInfo:
      configMapName: be-conf
      resolveKey: be.conf
```

Tip

Please use the startup configMap to mount files, when you want mount the file into the config directory in container, the config directory is `/${DORIS_HOME}/conf`.

Mounting multiple ConfigMaps

The Doris Operator supports mounting multiple ConfigMaps into different directories within the container, allowing flexible configuration management.

Mounting multiple ConfigMaps for FE

The following example demonstrates how to mount two ConfigMaps `test-fe1` and `test-fe2` to the directories `"/etc/fe/config1/"` and `"/etc/fe/config2"`, respectively, within the FE container:

```
spec:
  feSpec:
    configMaps:
      - configMapName: test-fe1
        mountPath: /etc/fe/config1
      - configMapName: test-fe2
        mountPath: /etc/fe/config2
```

Mounting multiple ConfigMaps for BE

Similarly, the following example shows how to mount two ConfigMaps `test-be1` and `test-be2` into the directories `"/etc/be/config1"` and `"/etc/be/config2"`, respectively, within the BE container:

```
spec:
  beSpec:
```

```
configMaps:
- configMapName: test-be1
  mountPath: /etc/be/config1
- configMapName: test-be2
  mountPath: /etc/be/config2
```

Persistent storage

Kubernetes provides the [Persistent Volumes](#) to persist data to physical storage. In Kubernetes, the Doris Operator automatically creates PersistentVolumeClaims associated with appropriate PersistentVolumes, based on the template that defined in the need deployed [DorisCluster Resource](#).

Persistent storage for FE

In a Kubernetes-based Doris deployment, it is recommended to persist the following paths for FE:

1. Metadata: /opt/apache-doris/fe/doris-meta (default storage configuration for FE metadata).
2. Logs: /opt/apache-doris/fe/log (if log persistence is required).

Persistent metadata for FE

To persist FE metadata using the default storage configuration, add the following configuration to the [DorisCluster resource](#):

```
spec:
  feSpec:
    persistentVolumes:
    - mountPath: /opt/apache-doris/fe/doris-meta
      name: meta
    persistentVolumeClaimSpec:
      # when use specific storageclass, the storageClassName should reConfig, example as annotation.
      storageClassName: ${your_storageclass}
      accessModes:
      - ReadWriteOnce
      resources:
        # notice: if the storage size less 5G, fe will not start normal.
        requests:
          storage: ${storageSize}
```

In the above configuration, `${your_storageclass}` represents the name of the StorageClass you want to use, and `${storageSize}` represents the storage size you want to allocation. The format is [quantity expression](#), such as: 100Gi.

Persistent FE log

If your cluster lacks a centralized log collection system, persist the FE log directory by adding the following configuration to the [DorisCluster resource](#):

```
spec:
  feSpec:
    persistentVolumes:
    - mountPath: /opt/apache-doris/fe/log
      name: log
```

```

persistentVolumeClaimSpec:
  # when use specific storageclass, the storageClassName should reConfig, example as annotation.
  storageClassName: ${your_storageclass}
  accessModes:
    - ReadWriteOnce
  resources:
    # notice: if the storage size less 5G, fe will not start normal.
    requests:
      storage: ${storageSize}

```

In the above configuration, `${your_storageclass}` represents the name of the StorageClass you want to use, and `${storageSize}` represents the storage size you want to allocation. The format of `${storageSize}` follows the [quantity expression](#) method of K8s, such as: 100Gi. Please replace them as needed when using.

Tip

If you have reconfigured `meta_dir` or `LOG_DIR` in the [customized configuration file](#), please reconfigure the `mountPath`.

Persistent storage for BE

For BE nodes in a Doris deployment, it is recommended to persist the following paths:

1. Data Storage: `/opt/apache-doris/be/storage` (default storage for BE data). 2. Logs: `/opt/apache-doris/be/log` (if log persistence is required).

Persistent data

- **Using default storage configuration**

To persist data uses the default storage configuration, update the [DorisCluster resource](#) with the following configuration:

```

beSpec:
  persistentVolumes:
    - mountPath: /opt/apache-doris/be/storage
      name: be-storage
  persistentVolumeClaimSpec:
    storageClassName: ${your_storageclass}
    accessModes:
      - ReadWriteOnce
    resources:
      requests:
        storage: ${storageSize}

```

In the above configuration, `${your_storageclass}` represents the name of the StorageClass you want to use, and `${storageSize}` represents the storage size you want to use. The format of `${storageSize}` follows the [quantity expression method](#) of K8s, such as: 100Gi. Please replace them as needed when using.

- **Customizing BE storage paths**

To leverage multiple disks, you can configure multiple storage directories using `storage_root_path`. For

example, if `storage_root_path=/home/disk1/doris.HDD;/home/disk2/doris.SSD`, the configuration should include:

```
beSpec:
  persistentVolumes:
  - mountPath: /home/disk1/doris
    name: be-storage1
    persistentVolumeClaimSpec:
      storageClassName: ${your_storageclass}
      accessModes:
      - ReadWriteOnce
      resources:
        requests:
          storage: ${storageSize}
  - mountPath: /home/disk2/doris
    name: be-storage2
    persistentVolumeClaimSpec:
      storageClassName: ${your_storageclass}
      accessModes:
      - ReadWriteOnce
      resources:
        requests:
          storage: ${storageSize}
```

In the above configuration, `${your_storageclass}` represents the name of the StorageClass you want to use, and `${storageSize}` represents the storage size you want to use. The format of `${storageSize}` follows the [quantity expression method](#) of K8s, such as: 100Gi. Please replace them as needed when using.

Persistent BE log

To persist BE logs when using the default configuration, update the DorisCluster resource [DorisCluster resource](#) as follows:

```
beSpec:
  persistentVolumes:
  - mountPath: /opt/apache-doris/be/log
    name: belong
    persistentVolumeClaimSpec:
      storageClassName: ${your_storageclass}
      accessModes:
      - ReadWriteOnce
      resources:
        requests:
          storage: ${storageSize}
```

In the above configuration, `${your_storageclass}` represents the name of the StorageClass you want to use, and `${storageSize}` represents the storage size you want to use. The format of `${storageSize}` follows the [quantity expression method](#) of K8s, such as: 100Gi. Please replace them as needed when using.

Access configuration

Kubernetes provides the use of Service as VIP (Virtual IP) and load balancer. There are three external exposure modes for Service: ClusterIP, NodePort, and LoadBalancer.

ClusterIP

Doris provides the ClusterIP access mode by default on Kubernetes. The ClusterIP access mode provides an internal IP address within the Kubernetes cluster to expose services through this internal IP. With the ClusterIP mode, services can only be accessed within the cluster.

Step 1: Configure ClusterIP

Doris provides the ClusterIP access mode by default on Kubernetes. You can use the ClusterIP access mode without any modification.

Step 2: Obtain the Service

After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectl -n doris get svc
```

The returned result is as follows:

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)
doriscluster-sample-be-internal 9m	ClusterIP	None	<none>	9050/TCP
doriscluster-sample-be-service 9m	ClusterIP	10.1.68.128	<none>	9060/TCP,8040/TCP,9050/TCP,8060/TCP
doriscluster-sample-fe-internal 14m	ClusterIP	None	<none>	9030/TCP
doriscluster-sample-fe-service 14m	ClusterIP	10.1.118.16	<none>	8030/TCP,9020/TCP,9030/TCP,9010/TCP

In the above results, there are two types of services for FE and BE, with suffixes of “internal” and “service” respectively: - The services with the “internal” suffix can only be used for internal communication within Doris, such as heartbeat, data exchange, and other operations, and are not for external use. - The services with the “service” suffix can be used by users.

Step 3: Access doris from inside the container

You can create a pod containing the mysql client in the current Kubernetes cluster using the following command:

```
kubectl run mysql-client --image=mysql:5.7 -it --rm --restart=Never --namespace=doris -- /bin/bash
```

From within the container in the cluster, you can access the Doris cluster using the service name with the “service” suffix that is exposed externally:

```
mysql -uroot -P9030 -hdoriscluster-sample-fe-service
```

NodePort

To access Doris from outside the Kubernetes cluster, you can use the NodePort service type. There are two ways to allocate a port for the NodePort: dynamic allocation and static allocation.

- Dynamic Allocation: If the port is not explicitly set, Kubernetes will automatically allocate an unused port from the default range (30000-32767) when the pod is created. - Static Allocation: If a port is explicitly specified, Kubernetes will allocate that port if it is available, ensuring it remains fixed.

Doris exposes the following ports for external access:

Port Name	default value	Port Description
Query Port	9030	Used to access the Doris cluster via the MySQL protocol
HTTP Port	8030	The http server port on FE, used to view FE information
Web Server Port	8040	The http server port on BE, used to view BE information

Step 1: Configure NodePort

FE NodePort

- Dynamic Allocation: `yaml spec: feSpec: service: type: NodePort` - Static Allocation: `yaml spec: feSpec: service: type: NodePort servicePorts: - nodePort: 31001 targetPort: 8030 - nodePort: 31002 targetPort: 9030`

BE NodePort - Dynamic Allocation: `yaml spec: beSpec: service: type: NodePort` - Static Allocation: `yaml beSpec: service: type: NodePort servicePorts: - nodePort: 31006 targetPort: 8040 #####`
Step 2: Obtain the service After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectll get service
```

The returned result is as follows:

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)
AGE				
kubernetes	ClusterIP	10.152.183.1	<none>	443/TCP
169d				
doriscluster-sample-fe-internal	ClusterIP	None	<none>	9030/TCP
2d				
doriscluster-sample-fe-service	NodePort	10.152.183.58	<none>	8030:31041/TCP,9020:30783/TCP,9030:31545/TCP,9010:31610/TCP
2d				
doriscluster-sample-be-internal	ClusterIP	None	<none>	9050/TCP
2d				
doriscluster-sample-be-service	NodePort	10.152.183.244	<none>	9060:30940/TCP,8040:32713/TCP,9050:30621/TCP,8060:30926/TCP
2d				

Step 3: Access service using NodePort

To access Doris via NodePort, you need to know the Node IP and the mapped port. You can retrieve the node IPs using:

```
kubectl get nodes -owide
```

Example output::

NAME	STATUS	ROLES	AGE	VERSION	INTERNAL-IP	EXTERNAL-IP	OS-IMAGE	KERNEL- VERSION
r60	Ready	control-plane	14d	v1.28.2	192.168.88.60	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r61	Ready	<none>	14d	v1.28.2	192.168.88.61	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r62	Ready	<none>	14d	v1.28.2	192.168.88.62	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r63	Ready	<none>	14d	v1.28.2	192.168.88.63	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						

You can then use the IP address of any node (e.g., 192.168.88.61, 192.168.88.62, or 192.168.88.63) along with the mapped port to access Doris. For example, using node 192.168.88.62 and port 31545:

```
mysql -h 192.168.88.62 -P 31545 -uroot
```

LoadBalancer

[LoadBalancer](#) service type provides an additional load balancer, typically offered by cloud service providers.

This mode is only available when deploying the Doris cluster on Kubernetes clusters managed by a cloud

platform. ##### Step 1: Configure the LoadBalancer mode

FE LoadBalancer

```
spec:
  feSpec:
    service:
      type: LoadBalancer
```

BE LoadBalancer

```
spec:
  beSpec:
    service:
      type: LoadBalancer
```

Step 2: Obtain the service

After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectl get service
```

The returned result is as follows:

NAME PORT(S)	TYPE	CLUSTER-IP	EXTERNAL-IP AGE
kubernetes 443/TCP	ClusterIP	10.152.183.1	<none> 169d
doriscluster-sample-fe-internal 9030/TCP	ClusterIP	None	<none> 2d
doriscluster-sample-fe-service 1137856348.us-east-1.elb.amazonaws.com	LoadBalancer	10.152.183.58 8030:31041/TCP,9020:30783/TCP,9030:31545/TCP,9010:31610/TCP	ac4828493dgrftb884g67wg4tb68gyut- 2d
doriscluster-sample-be-internal 9050/TCP	ClusterIP	None	<none> 2d
doriscluster-sample-be-service 1137823345.us-east-1.elb.amazonaws.com	LoadBalancer	10.152.183.244 9060:30940/TCP,8040:32713/TCP,9050:30621/TCP,8060:30926/TCP	ac4828493dgrftb884g67wg4tb68gyut- 2d

Step 3: Access service using LoadBalancer

To access Doris through the LoadBalancer, use the external IP (provided in the EXTERNAL-IP field) and the corresponding port. For example, using the `mysql` command:

```
mysql -h ac4828493dgrftb884g67wg4tb68gyut-1137856348.us-east-1.elb.amazonaws.com -P 31545 -uroot
```

Configuring the username and password for the management cluster

Managing Doris nodes requires connecting to the live FE nodes via the MySQL protocol using a username and password for administrative operations. Doris implements [a permission management mechanism similar to RBAC](#), where the user must have the `Node_priv` permission to perform node management. By default, the Doris Operator deploys the cluster with the root user in passwordless mode.

The process of configuring the username and password can be divided into three scenarios:

- initializing the root user password during cluster deployment;
- automatically setting a non-root user with management permissions in the root passwordless deployment;
- setting the root user password after deploying the cluster in root passwordless mode.

To secure access, you must configure a username and password with `Node_Priv` permission in the DorisCluster resource after adding a password to the root user. There are two ways to set up the username and password for managing the cluster nodes: - Using environment variables - Using a Kubernetes Secret

Configuring the root user password during cluster deployment

To set the root user's password securely, Doris supports encrypting it in `fe.conf` using a two-stage SHA-1 encryption process. Here's how to set up the password.

Step 1: Generate the root encrypted password

Use the following methods to encrypt the root password using two-stage SHA-1 encryption:

- Java Code:

```
import org.apache.commons.codec.digest.DigestUtils;

public static void main( String[] args ) {
    //the original password
    String a = "123456";
    String b = DigestUtils.sha1Hex(DigestUtils.sha1(a.getBytes())).toUpperCase();
    //output the 2 stage encrypted password.
    System.out.println("*"+b);
}
```

- Golang Code:

```
import (
    "crypto/sha1"
    "encoding/hex"
    "fmt"
    "strings"
)

func main() {
    //original password
    plan := "123456"
    //the first stage encryption.
    h := sha1.New()
    h.Write([]byte(plan))
    eb := h.Sum(nil)

    //the two stage encryption.
    h.Reset()
    h.Write(eb)
    teb := h.Sum(nil)
    dst := hex.EncodeToString(teb)
    tes := strings.ToUpper(fmt.Sprintf("%s", dst))
    //output the 2 stage encrypted password.
    fmt.Println("*"+tes)
}
```

Configure the encrypted password into `fe.conf` according to the requirements of the configuration file format. Then, Then, distribute the configuration to the Kubernetes cluster using a ConfigMap, describes in [the Cluster Parameter Configuration Section](#).

Step 2: Configure the DorisCluster resource

After setting the root password in `fe.conf`, Doris will automatically apply the password to the first FE node when it starts. For other nodes to join the cluster, specify the username and password in the DorisCluster resource so that Doris Operator can perform automatic node management. - Using environment variables

Configure the username root and password into the `".spec.adminUser.name"` and `".spec.adminUser.password"` fields in the DorisCluster resource. Doris Operator will automatically convert the following configuration into environment variables for the container to use. The auxiliary services inside the container will use the username and password configured by the environment variables to add themselves to the specified cluster. The configuration format is as follows:

```
spec:
  adminUser:
```

```
name: root
password: ${password}
```

Here, `${password}` is the unencrypted password of root.

- Using secret

To securely manage the username and password, you can use a Kubernetes [Basic Authentication Secret](#). Configure the Secret to store the root username and password and reference it in the DorisCluster resource.

a. Configure the Required Secret

Configure the required Basic authentication Secret according to the following format:

```
stringData:
  username: root
  password: ${password}
```

Here, `${password}` is the unencrypted password set for root.

b. Configure the DorisCluster Resource to be Deployed

Configure the DorisCluster to specify the required Secret in the following format:

```
spec:
  authSecret: ${secretName}
```

Here, `${secretName}` is the name of the Secret containing the root username and password.

Automatically creating non-root management users and passwords during deployment (Recommended)

For enhanced security, it is recommended to create a non-root user for management during the first deployment, rather than using the root user. In this method, the username and password for the non-root user are configured through environment variables or Secrets. The Doris container's auxiliary services will automatically create the user in the database, set the password, and grant the necessary `Node_priv` permission. After deployment, Doris Operator will use the newly created non-root username and password to manage the cluster nodes.

- Using environment variables:

To configure a non-root user, you can set the username and password using environment variables in the DorisCluster resource: `yaml spec: adminUser: name: ${DB_ADMIN_USER} password: ${DB_ADMIN_PASSWD}`

Here, `${DB_ADMIN_USER}` is the newly created username, and `${DB_ADMIN_PASSWD}` is the password set for the newly created username.

- Using Secret: To securely manage the username and password, you can use a Kubernetes Secret for basic authentication.

a. Configure the required secret

```
stringData:
  username: ${DB_ADMIN_USER}
  password: ${DB_ADMIN_PASSWD}
```

Here, `${DB_ADMIN_USER}` is the newly created username, and `${DB_ADMIN_PASSWD}` is the password set for the newly created username.

Deploy the Secret to the Kubernetes cluster by running:

```
kubectl -n ${namespace} apply -f ${secretFileName}.yaml
```

Here, `${namespace}` is the namespace where the DorisCluster resource needs to be deployed, and `${secretFileName}` is the file name of the Secret to be deployed.

b. Configure the DorisCluster resource

Update the DorisCluster resource according to the following format:

```
spec:
  authSecret: ${secretName}
```

Here, `${secretName}` is the name of the deployed Basic authentication Secret.

Tip

After deployment, please set the root password. Doris Operator will switch to using the automatically newly created username and password to manage the nodes. Please avoid deleting the automatically created user.

Setting the root user password after cluster deployment

After deploying the Doris cluster and setting the root user's password, it's essential to create a management user with the necessary [Node_priv](#) permission to allow Doris Operator to automatically manage the cluster nodes. Using the root user for this purpose is not recommended. Instead, please refer to [the User Creation and Permission Assignment Section](#) to create a new user and grant Node_priv permission.

Step 1: Create a user with Node_priv permission

First, connect to the Doris database using the MySQL protocol, then create a new user with the required permissions: `shell CREATE USER '${DB_ADMIN_USER}' IDENTIFIED BY '${DB_ADMIN_PASSWD}';`

- `${DB_ADMIN_USER}`: The name of the user you wish to create.
- `${DB_ADMIN_PASSWD}`: The password for the newly created user.

step 2: Grant Node_priv permission to the new user

Grant the Node_priv permission to the newly created user:

```
GRANT NODE_PRIV ON *.* TO ${DB_ADMIN_USER};
```

`${DB_ADMIN_USER}`: The username you created in the previous step.

For more details on creating users, setting passwords, and granting permissions, refer to the [CREATE-USER](#) section.

step 3: Configure DorisCluster

- Using environment variables

Directly configure the new user's name and password in the DorisCluster resource:

```
spec:
  adminUser:
    name: ${DB_ADMIN_USER}
    password: ${DB_ADMIN_PASSWD}
```

Here, `${DB_ADMIN_USER}` is the newly created username, and `${DB_ADMIN_PASSWD}` is the password set for the newly created user.

- Using Secret To securely manage the username and password, you can use Kubernetes Secrets.
 - a. Create the required secret
Create a Basic Authentication Secret for the new user:

```
stringData:
  username: ${DB_ADMIN_USER}
  password: ${DB_ADMIN_PASSWD}
```

Here, `${DB_ADMIN_USER}` is the newly created username, and `${DB_ADMIN_PASSWD}` is the password set for the newly created username.

Deploy the Secret to the Kubernetes cluster with:

```
kubectl -n ${namespace} apply -f ${secretFileName}.yaml
```

Here, `${namespace}` is the namespace where the DorisCluster resource needs to be deployed, and `${secretFileName}` is the file name of the Secret to be deployed.

- b. Update the DorisCluster resource

Once the Secret is deployed, update the DorisCluster resource to specify the Secret:

```
spec:
  authSecret: ${secretName}
```

Here, `${secretName}` is the name of the deployed Basic authentication Secret.

Tip

After setting the root password and configuring the new username and password for managing nodes after deployment, the existing services will be restarted once in a rolling manner.

Automatic Service Restart on Configuration Changes

Doris specifies startup parameters through configuration files. While most parameters can be modified through web interfaces and take effect immediately, certain parameters requiring service restart can now be automatically handled through Doris Operator's restart capability introduced in version 25.1.0.

To enable this functionality in a `DorisCluster` resource, configure:

```
spec:
  enableRestartWhenConfigChange: true
```

When this configuration is present, Doris Operator will:

1. Monitor changes to cluster startup configurations (mounted via ConfigMap, see [Customizing Startup Configurations](#)).
2. Automatically restart affected services when configurations change.

Example Usage

Support configmap monitoring and restart for FE and BE, Use FE usage as example. 1. Sample `DorisCluster` deployment specification: `yaml spec: enableRestartWhenConfigChange: true feSpec: image: apache/doris:fe-2.1.8 replicas: 1 configMapInfo: configMapName: fe-configmap` 2. Update FE service configurations.

When modifying values under the `fe.conf` key in the `fe-configmap` ConfigMap (containing FE service configurations), Doris Operator will automatically perform a rolling restart of FE services to apply changes.

Using Kerberos Authentication

The Doris Operator has supported Kerberos authentication for Doris (versions 2.1.9, 3.0.4, and later) in Kubernetes since version 25.2.0. To enable Kerberos authentication in Doris, both the [krb5.conf file](#) and [keytab files](#) are required. The Doris Operator mounts the `krb5.conf` file using a ConfigMap resource and mounts the keytab files using a Secret resource. The workflow for enabling Kerberos authentication is as follows:

1. Create a ConfigMap containing the `krb5.conf` file: `shell kubectl create -n ${namespace} configmap ${name} --from-file=krb5.conf` Replace `${namespace}` with the namespace where the `DorisCluster` is deployed, and `${name}` with the desired name for the ConfigMap.
2. Create a Secret containing the keytab files: `shell kubectl create -n ${namespace} secret generic ${name} --from-file=${xxx.keytab}` Replace `${namespace}` with the namespace where the `DorisCluster` is deployed, and `${name}` with the desired name for the Secret. If multiple keytab files need to be mounted, refer to the [kubectl create Secret documentation](#) to include them in a single Secret.
3. Configure the `DorisCluster` resource to specify the ConfigMap containing `krb5.conf` and the Secret containing keytab files: `yaml spec: kerberosInfo: krb5ConfigMap: ${krb5ConfigMapName} keytabSecretName: ${keytabSecretName} keytabPath: ${keytabPath} ${krb5ConfigMapName}:`

Name of the ConfigMap containing the krb5.conf file. `${keytabSecretName}`: Name of the Secret containing the keytab files. `${keytabPath}`: The directory path in the container where the Secret mounts the keytab files. This path should match the directory specified by `hadoop.kerberos.keytab` when creating a catalog. For catalog configuration details, refer to the [Hive Catalog configuration](#) documentation.

Configure Shared Storage

As of version 25.4.0, the Doris Operator supports mounting shared storage with the `ReadWriteMany` access mode to all pods across multiple components. Before using this feature, ensure that the shared storage `PersistentVolume` and `PersistentVolumeClaim` resources have been created. Configure the `DorisCluster` resource as shown below before deploying the Doris cluster:

```
spec:
  sharedPersistentVolumeClaims:
  - mountPath: ${mountPath}
    persistentVolumeClaimName: ${sharedPVCName}
  supportComponents:
  - fe
  - be
```

- `${mountPath}` specifies the absolute path inside the container where the storage will be mounted.
- `${sharedPVCName}` refers to the name of the `PersistentVolumeClaim` to be mounted.
- `supportComponents` lists the names of the components that require the shared storage. In the example above, both the FE and BE components will mount the shared storage. If the `supportComponents` array is left empty, all deployed components will mount the shared storage by default.

Tip

The `mountPath` parameter can use `${DORIS_HOME}` as a prefix. When `${DORIS_HOME}` is used, it resolves to `/opt/apache-doris/fe` within FE containers and `/opt/apache-doris/be` within BE containers.

Configuring Probe Timeouts

`DorisCluster` provides two types of probe timeout configurations for each service: `startup probe timeout` and `liveness probe timeout`. If a service fails to start within the specified startup timeout period, it is considered to have failed and will be restarted. If a service becomes unresponsive for longer than the specified liveness timeout, the corresponding Pod will be automatically restarted.

Startup Probe Timeout

- FE Service Startup Timeout Configuration
spec: feSpec: startTimeout: 3600 The above configuration sets the FE service startup timeout to 3600 seconds.
- BE Service Startup Timeout Configuration
spec: beSpec: startTimeout: 3600 ##### Liveness Probe Timeout

- FE Service Liveness Timeout Configuration

spec: feSpec: liveTimeout: 60 The above configuration sets the FE service liveness timeout to 60 seconds.

- BE Service Liveness Timeout Configuration

spec: beSpec: liveTimeout: 60 The above configuration sets the BE service liveness timeout to 60 seconds.

Deploy Doris Cluster

To deploy a Doris cluster on Kubernetes, ensure that [the Doris Operator is deployed](#).

The deployment process for a Doris cluster consists of three steps: download the deployment template, custom the template and deploy cluster, and verify the cluster status. ### Step 1: Download the Doris deployment template

```
curl -O https://raw.githubusercontent.com/apache/doris-operator/master/doc/examples/doriscluster-sample.yaml
```

Step 2: Custom the template and deploy cluster

Perform customized configuration as needed according to the doc of [Config Doris to Deploy](#). After the configuration is completed, deploy it with the following command:

```
kubectl apply -f doriscluster-sample.yaml
```

Step 3: Verify the cluster status

- Check the status of the cluster by checking the status of pods

```
kubectl get pods
```

Expected output:

NAME	READY	STATUS	RESTARTS	AGE
doriscluster-sample-fe-0	1/1	Running	0	2m
doriscluster-sample-be-0	1/1	Running	0	3m

- Check the status of the deployed resources

```
kubectl get dcr -n doris
```

Expected output:

NAME	FESTATUS	BESTATUS	CNSTATUS	BROKERSTATUS
doriscluster-sample	available	available		

Access Cluster

Kubernetes provides the use of Service as VIP (Virtual IP) and load balancer. There are three external exposure modes for Service: ClusterIP, NodePort, and LoadBalancer. ### ClusterIP Doris provides the ClusterIP access mode by default on Kubernetes. The ClusterIP access mode provides an internal IP address within the Kubernetes cluster to expose services through this internal IP. With the ClusterIP mode, services can only be accessed within the cluster. ##### Step 1: Obtain the Service After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectl -n doris get svc
```

The returned result is as follows:

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)
AGE				
doriscluster-sample-be-internal 9m	ClusterIP	None	<none>	9050/TCP
doriscluster-sample-be-service 9m	ClusterIP	10.1.68.128	<none>	9060/TCP,8040/TCP,9050/TCP,8060/TCP
doriscluster-sample-fe-internal 14m	ClusterIP	None	<none>	9030/TCP
doriscluster-sample-fe-service 14m	ClusterIP	10.1.118.16	<none>	8030/TCP,9020/TCP,9030/TCP,9010/TCP

In the above results, there are two types of services for FE and BE, with suffixes of “internal” and “service” respectively: - The services with the “internal” suffix can only be used for internal communication within Doris, such as heartbeat, data exchange, and other operations, and are not for external use. - The services with the “service” suffix can be used by users.

Step 2: Access Doris

You can create a pod containing the mysql client in the current Kubernetes cluster using the following command:

```
kubectl run mysql-client --image=mysql:5.7 -it --rm --restart=Never --namespace=doris -- /bin/bash
```

From within the container in the cluster, you can access the Doris cluster using the service name with the “service” suffix that is exposed externally:

```
mysql -uroot -P9030 -hdoriscluster-sample-fe-service
```

NodePort

According to the DorisCluster access configuration section, after [configuring the access mode to use NodePort](#), you can access FE using the MySQL protocol in root password-free mode. The steps are as follows: ##### Step

1: Obtain the service After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectl get service
```

The returned result is as follows:

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)
AGE kubernetes 169d	ClusterIP	10.152.183.1	<none>	443/TCP
doriscluster-sample-fe-internal 2d	ClusterIP	None	<none>	9030/TCP
doriscluster-sample-fe-service 8030:31041/TCP,9020:30783/TCP,9030:31545/TCP,9010:31610/TCP 2d	NodePort	10.152.183.58	<none>	
doriscluster-sample-be-internal 2d	ClusterIP	None	<none>	9050/TCP
doriscluster-sample-be-service 9060:30940/TCP,8040:32713/TCP,9050:30621/TCP,8060:30926/TCP 2d	NodePort	10.152.183.244	<none>	

Step 2: Access Doris

To access Doris via NodePort, you need to know the Node IP and the mapped port. You can retrieve the node IPs using:

```
kubectl get nodes -owide
```

Example output::

NAME	STATUS	ROLES	AGE	VERSION	INTERNAL-IP	EXTERNAL-IP	OS-IMAGE	KERNEL-
VERSION		CONTAINER-RUNTIME						
r60	Ready	control-plane	14d	v1.28.2	192.168.88.60	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r61	Ready	<none>	14d	v1.28.2	192.168.88.61	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r62	Ready	<none>	14d	v1.28.2	192.168.88.62	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						
r63	Ready	<none>	14d	v1.28.2	192.168.88.63	<none>	CentOS Stream 8	4.18.0-
294.el8.x86_64		containerd://1.6.22						

You can then use the IP address of any node (e.g., 192.168.88.61, 192.168.88.62, or 192.168.88.63) along with the mapped port to access Doris. For example, using node 192.168.88.62 and port 31545:

```
mysql -h 192.168.88.62 -P 31545 -uroot
```

LoadBalancer

According to the DorisCluster access configuration section, on a public cloud platform, after [configuring the access mode to use LoadBalancer](#), you can access FE using the MySQL protocol in root password-free mode. The steps are as follows: ##### Step 1: Obtain the service After deploying the cluster, you can view the services exposed by the Doris Operator using the following command:

```
kubectl get service
```

The returned result is as follows:

NAME PORT(S)	TYPE	CLUSTER-IP	EXTERNAL-IP AGE
kubernetes 443/TCP	ClusterIP	10.152.183.1	<none> 169d
doriscluster-sample-fe-internal 9030/TCP	ClusterIP	None	<none> 2d
doriscluster-sample-fe-service 1137856348.us-east-1.elb.amazonaws.com	LoadBalancer	10.152.183.58 8030:31041/TCP,9020:30783/TCP,9030:31545/TCP,9010:31610/TCP	ac4828493dgrftb884g67wg4tb68gyut- 2d
doriscluster-sample-be-internal 9050/TCP	ClusterIP	None	<none> 2d
doriscluster-sample-be-service 1137823345.us-east-1.elb.amazonaws.com	LoadBalancer	10.152.183.244 9060:30940/TCP,8040:32713/TCP,9050:30621/TCP,8060:30926/TCP	ac4828493dgrftb884g67wg4tb68gyut- 2d

Step 2: Access Doris

To access Doris through the LoadBalancer, use the external IP (provided in the EXTERNAL-IP field) and the corresponding port. For example, using the `mysql` command:

```
mysql -h ac4828493dgrftb884g67wg4tb68gyut-1137856348.us-east-1.elb.amazonaws.com -P 31545 -uroot
```

StreamLoad Access to Doris Deployed on Kubernetes

Doris supports data import using the StreamLoad method. When the client and the Doris cluster are within the same local network, the client can directly use the Frontend (FE) address as the request endpoint. The FE service responds with an HTTP 301 status code and provides the Backend (BE) address, instructing the client to redirect the request to the BE for data import.

However, when Doris is deployed on Kubernetes, internal communication uses addresses that are only accessible within the Kubernetes cluster. If the FE returns a BE address that is only reachable internally via the 301 redirect mechanism, data import attempts from clients outside the Kubernetes cluster will fail.

To import data using StreamLoad from a client located outside the Kubernetes environment, you must configure the import address with a BE address that is externally accessible.

Configure External Access to the BE Service

To enable access to the BE service from outside the Kubernetes cluster, configure the service as either a [NodePort](#) or a [LoadBalancer](#). Update the `DorisCluster` resource accordingly to apply these changes.

Configure the BE Proxy Address

As the description of [NodePort](#) or [LoadBalancer](#) to get an externally accessible address and the corresponding `web_server` port. Use this address and port as the request endpoint when importing data via StreamLoad.

Cluster Operation

How to enter the container when the pod crashes

In the k8s environment, the service will enter the `CrashLoopBackOff` state due to some unexpected things. You can view the pod status and pod_name under the specified namespace through the `kubectl get pod --namespace ${namespace}` command.

In this state, the cause of the service problem cannot be determined simply by using the `describe` and `logs` commands. When the service enters the `CrashLoopBackOff` state, there needs to be a mechanism that allows the pod deploying the service to enter the running state so that users can enter the container for debugging through `exec`.

doris-operator provides a Debug running mode. The following describes how to enter Debug mode for manual debugging when the service enters `CrashLoopBackOff`, and how to return to normal startup state after solving the problem.

Start Debug mode

When a pod of the service enters `CrashLoopBackOff` or cannot be started normally during normal operation, take the following steps to put the service into Debug mode and manually start the service to find the problem.

1. Use the following command to add annotation to the pod with problems.

```
$ kubectl annotate pod ${pod_name} --namespace ${namespace} apache.org.doris/runmode=debug
```

When the service is restarted next time, the service will detect the annotation that identifies the Debug mode startup, and will enter the Debug mode to start, and the pod status will be running.

2. When the service enters Debug mode, the pod of the service is displayed in a normal state. Users can enter the inside of the pod through the following command

```
$ kubectl --namespace ${namespace} exec -ti ${pod_name} bash
```

3. Manually start the service under Debug. When the user enters the pod, manually execute the `start_xx.sh` script by modifying the port of the corresponding configuration file. The script directory is under `/opt/apache-doris/xx/bin`.

FE needs to modify `query_port`, BE needs to modify `heartbeat_service_port`. The main purpose is to avoid misleading the flow by accessing the crashed node through service in Debug mode.

Exit Debug mode

When the service locates the problem, it needs to exit the Debug operation. At this time, you only need to delete the corresponding pod according to the following command, and the service will start in the normal mode.

```
$ kubectl delete pod ${pod_name} --namespace ${namespace}
```

Tip

After entering the pod, you need to modify the port information of the configuration file before you can manually start the corresponding Doris component.

- FE needs to modify the query_port=9030 configuration with the default path: /opt/apache-doris/fe/conf/fe.conf.
- BE needs to modify the heartbeat_service_port=9050 configuration with the default path: /opt/apache-doris/be/conf/be.conf.

Upgrading doris cluster

This document describes how to use updates to upgrade an Apache Doris cluster based on a Doris Operator deployment.

Similar to conventionally deployed cluster upgrades, Doris clusters deployed by Doris Operator still require rolling upgrades from BE to FE nodes. Doris Operator is based on Kubernetes' [Performing a Rolling Update](#) provides rolling upgrade capabilities.

Things to note before upgrading

- It is recommended that the upgrade operation be performed during off-peak periods.
- During the rolling upgrade process, the connection to the closed node will fail, causing the request to fail. For this type of business, it is recommended to add retry capabilities to the client.
- Before upgrading, you can read the [General Upgrade Manual](#) to help you understand some principles and precautions during the upgrade. .
- The compatibility of data and metadata cannot be verified before upgrading. Therefore, cluster upgrade must avoid single copy of data and single FE FOLLOWER node in the cluster.
- Nodes will be restarted during the upgrade process, so unnecessary cluster balancing and replica repair logic may be triggered. Please shut it down first with the following command.

```
admin set frontend config("disable_balance" = "true");  
admin set frontend config("disable_colocate_balance" = "true");  
admin set frontend config("disable_tablet_scheduler" = "true");
```

- When upgrading Doris, please follow the principle of not upgrading across two or more key node versions. If you want to upgrade across multiple key node versions, upgrade to the latest key node version first, and then upgrade in sequence. If it is a non-key node version, You can ignore skipping. For details, please refer to [Upgrade Version Instructions](#)

Upgrade operation

The order of node types in the upgrade process is as follows. If a certain type of node does not exist, it will be skipped:

```
cn/be -> fe -> broker
```

It is recommended to modify the image of the corresponding cluster components in sequence and then apply the configuration. After the current type of component is fully upgraded and the status returns to normal, the rolling upgrade of the next type of node can be performed.

Upgrade BE

If you retain the cluster's crd (Doris Operator defines the abbreviation of DorisCluster type resource name) file, you can upgrade by modifying the configuration file and running the `kubectl apply` command.

1. Modify `spec.beSpec.image`

Change `apache/doris:be-2.1.8` to `apache/doris:be-2.1.9` shell `$ vim doriscluster-sample.yaml`

2. Save the changes and apply the changes to be upgraded:

```
$ kubectl apply -f doriscluster-sample.yaml -n doris
```

It can also be modified directly through `kubectl edit dcr`.

1. Check the dcr list under namespace 'doris' to obtain the `cluster_name` that needs to be updated.

```
$ kubectl get dcr -n doris
NAME                FESTATUS    BESTATUS    CNSTATUS
doriscluster-sample available    available
```

2. Modify, save and take effect

```
$ kubectl edit dcr doriscluster-sample -n doris
```

After entering the text editor, you will find `spec.beSpec.image` and change `apache/doris:be-2.1.8` to `apache/doris:be-2.1.9`

3. View the upgrade process and results:

```
$ kubectl get pod -n doris
```

When all Pods are rebuilt and enter the Running state, the upgrade is complete.

Upgrade FE

If you retain the cluster's crd (Doris Operator defines the abbreviation of the DorisCluster type resource name) file, you can upgrade by modifying the configuration file and running the `kubectl apply` command.

1. Modify `spec.feSpec.image`

Change `apache/doris:fe-2.1.8` to `apache/doris:fe-2.1.9` shell `$ vim doriscluster-sample.yaml`

2. Save the changes and apply the changes to be upgraded:

```
$ kubectl apply -f doriscluster-sample.yaml -n doris
```

It can also be modified directly through `kubectl edit dcr`.

1. Modify, save and take effect

```
$ kubectl edit dcr doriscluster-sample -n doris
```

After entering the text editor, you will find `spec.feSpec.image` and change `apache/doris:fe-2.1.8` to `apache/doris:fe-2.1.9`

2. View the upgrade process and results:

```
$ kubectl get pod -n doris
```

When all Pods are rebuilt and enter the Running state, the upgrade is complete.

After the upgrade is completed

Verify cluster node status

Access Doris through `mysql-client` through the method provided in the [Access Doris Cluster](#) document. Use SQL such as `show frontends` and `show backends` to view the version and status of each component.

```
mysql> show frontends\G;

```

If the Alive status of the BE node is true and the Version value is the new version, the BE node is upgraded successfully.

Restore cluster replica synchronization and balancing

After confirming that the status of each node is correct, execute the following SQL to restore cluster balancing and replica repair:

```
admin set frontend config("disable_balance" = "false");
admin set frontend config("disable_colocate_balance" = "false");
admin set frontend config("disable_tablet_scheduler" = "false");
```

Starting FE with metadata_failure_recovery Mode

When the Frontend (FE) service is unable to elect a leader and becomes unavailable, you can recover the cluster by selecting the node with the highest VLSN and force-starting it as the master using the recovery mechanism.

Starting in Recovery Mode in a Containerized Environment

1. Identify the node with the highest VLSN

In Kubernetes, each time an FE Pod starts, it outputs the last 10 VLSN records of the node. An example is shown below: the annotations value: the value not equal! debug /opt/apache-doris/fe/doris-meta/bdb/je.info.0:19:2025-08-05 03:42:47.650 UTC INFO [fe_f35530c4_3ff1_48fe_80d1_cc8e32dbc942] Replica-feeder fe_d8763579_92da_4d72_8c58_4e62b88bdf0 start stream at VLSN: 30 /opt/apache-doris/fe/doris-meta/bdb/je.info.0:21:2025-08-05 03:42:47.659 UTC INFO [fe_f35530c4_3ff1_48fe_80d1_cc8e32dbc942] Replica initialization completed. Replica VLSN: -1 Heartbeat master commit VLSN: 49 DTVLSN:0 Replica VLSN delta: 50 [Tue Aug 5 06:14:05 UTC 2025] start with meta run start_fe.sh with additional options: '--console' In this example, the highest VLSN on the current node is 30, as indicated by the log prefix start stream at VLSN:.

2. Designate the Pod with the highest VLSN for recovery

After identifying the Pod corresponding to the node with the highest VLSN, annotate it to enable the recovery mechanism: `kubectl annotate pod {podName} "selectdb.com.doris/recovery=true"` Upon restarting, the Pod will automatically append the `--metadata_failure_recovery` flag to its startup command and start in recovery mode.

3. Remove the annotation after recovery

Once the FE service is running normally, make sure to remove the annotation added in Step 2 to avoid unexpected behavior during future restarts.

Note

1. After adding the annotation, do not restart the Pod using `kubectl delete pod`, as this will remove the annotation. Instead, allow kubelet to restart it automatically or manually kill the process inside the container.
2. Starting FE in `metadata_failure_recovery` mode can take a long time due to extensive log replay. Before proceeding, increase the FE service's [startup probe timeout](#), and delete all FE Pods before initiating the recovery startup.

Deploying on AWS

To facilitate a quick experience of Doris on AWS, we have provided a CloudFormation template (CFT) that allows for rapid cluster launch and operation. With this template, you can automatically configure AWS resources and launch a Doris cluster with minimal configuration required.

Alternatively, you can also purchase AWS resources independently and deploy the cluster manually using standard methods.

What's AWS CloudFormation?

CloudFormation enables users to create a “stack of resources” in just one step. Resources refer to the items created by users, such as EC2 instances, VPCs, subnets, and more. A group of such resources is referred to as a stack. Users can write a template that easily allows them to create a resource stack according to their preferences in a single step. This is faster, more repeatable, and offers better consistency compared to manual creation and configuration. Additionally, templates can be placed into source code for version control, enabling their use for any purpose whenever needed.

What's Doris on AWS CloudFormation?

Currently, Doris provides the Doris CloudFormation Template, which allows users to quickly create a cluster of the relevant Doris version on AWS by directly using this template, enabling them to experience the latest Doris features.

****Note: ** The template for building Doris clusters based on CloudFormation currently only supports the regions of us-east-1, us-west-1, and us-west-2. Doris on AWS CloudFormation is primarily intended for testing or experiencing purposes, and should not be used in production environments. **

Precautions for Use

- Determine the VPC and Subnet that will be deployed.
- Determine the key pair that will be used to log into the nodes.
- A VPC Endpoint Interface for S3 will be established during deployment.

Start Deployment

1. On the AWS console, navigate to CloudFormation and click on “Create stack”.

CloudFormation > Stacks > Create stack

Step 1
Create stack

Step 2
Specify stack details

Step 3
Configure stack options

Step 4
Review and create

Create stack

Prerequisite - Prepare template

Prepare template
Every stack is based on a template. A template is a JSON or YAML file that contains configuration information about the AWS resources you want to include in the stack.

☒ Template is ready ☐ Use a sample template ☐ Create template in Designer

Specify template
A template is a JSON or YAML file that describes your stack's resources and properties.

Template source
Selecting a template generates an Amazon S3 URL, where it will be stored.

☒ Amazon S3 URL ☐ Upload a template file ☐ Sync from Git - new

Provide an Amazon S3 URL to your template. Upload your template directly to the console. Sync a template from your Git repository.

Amazon S3 URL
https://sdb-cloud-third-party.s3.amazonaws.com/doris-cf/cloudformation_doris.template.yaml
Amazon S3 template URL

S3 URL: https://sdb-cloud-third-party.s3.amazonaws.com/doris-cf/cloudformation_doris.template.yaml [View in Designer](#)

[Cancel](#) [Next](#)

Start Deployment

Select the “Amazon S3 URL Template source” option, and fill in the “Amazon S3 URL” field with the following template link:

https://sdb-cloud-third-party.s3.amazonaws.com/doris-cf/cloudformation_doris.template.yaml

2. Configure the specific parameters of the template

CloudFormation > Stacks > Create stack

Step 1
[Create stack](#)

Step 2
Specify stack details

Step 3
Configure stack options

Step 4
Review and create

Specify stack details

Provide a stack name

Stack name
doris
Stack name can include letters (A-Z and a-z), numbers (0-9), and dashes (-).

Parameters
Parameters are defined in your template and allow you to input custom values when you create or update a stack.

Network configuration

VPC ID
ID of your existing VPC for deployment (e.g., vpc-fd990584)
vpc-01b44727828616981

Public Subnet ID
ID of public subnet in Availability Zone for the ELB load balancer (e.g., subnet-9bc642ac)
subnet-03c8fe3278ec0a2b8

EC2 configuration

Key pair name
Public/private key pairs allow you to securely connect to your instance after it launches.

EBS volume size (data) to be attached to node in GBs.
50

Cancel Previous Next

Configure the specific parameter

The main parameters are described as follows:

- **VPC ID:** The VPC where the deployment will be performed.
- **Subnet ID:** The subnet where the deployment will be deployed.
- **Key pair name:** The public/private key pairs used to connect to the deployed BE and FE nodes.
- **Version of Doris:** The version of Doris to be deployed, such as 2.1.0, 2.0.6, etc.
- **Number of Doris FE:** The number of FE nodes. The template defaults to selecting only 1 FE.
- **Fe instance type:** The node type of FE, and the default value can be used.
- **Number of Doris Be:** The number of BE nodes, which can be 1 or 3.
- **Be instance type:** The node type of BE, and the default value can be used.
- **Meta data dir:** The metadata directory of the FE node, and the default value can be used.
- **Sys log level:** Sets the level of system logs, and the default value of “info” can be used.
- **Volume type of Be nodes:** The volume type of EBS mounted on BE nodes. Each node is mounted with one disk by default. The default value can be used.

- **Volume size of Be nodes:** The size of EBS mounted on BE nodes, measured in GB. The default value can be used.

How to Connect to the Database

1. The display after successful deployment is as follows:

How to Connect to the Database

2. Next, find the connection address for FE as follows. In this example, you can view the address as **172.16.0.97** from the FE Outputs.

find the connection address for FE

find the connection address for FE

3. To connect to the deployed Doris Cluster, here are some default values after deploying Doris using CloudFormation:

- **FE IP:** Obtain the IP address of FE following the steps in the previous section.
- **FE MySQL protocol port:** 9030
- **FE HTTP protocol port:** 8030
- **Default root password:** empty
- **Default admin password:** empty

Connecting by MySQL Protocol

Apache Doris adopts the MySQL network connection protocol. It is compatible with command-line tools, JDBC/ODBC drivers, and various visualization tools within the MySQL ecosystem. Additionally, Apache Doris comes with a built-in, easy-to-use Web UI. This guide is about how to connect to Doris using MySQL Client, MySQL JDBC Connector, DBeaver, and the built-in Doris Web UI.

MySQL Client

Download MySQL Client from the [MySQL official website](#) for Linux. Currently, Doris is primarily compatible with MySQL 5.7 and later clients.

Extract the downloaded MySQL client. In the `bin/` directory, find the `mysql` command-line tool. Execute the following command to connect to Doris:

```
# FE_IP represents the listening address of the FE node, while FE_QUERY_PORT represents the port of the MySQL
protocol service of the FE. This corresponds to the query_port parameter in fe.conf and it defaults to 9030.
mysql -h FE_IP -P FE_QUERY_PORT -u USER_NAME
```

After login, the following message will be displayed.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 236
Server version: 5.7.99 Doris version doris-2.0.3-rc06-37d31a5
Copyright (c) 2000, 2018, Oracle and/or its affiliates. All rights reserved.
Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks
of their respective owners.                                     Type 'help;' or '\h' for help. Type '\c' to
clear the current input statement.                             mysql>
```

MySQL JDBC Connector

Download the corresponding JDBC Connector from the official MySQL website.

Example of connection code:

```
String user = "user_name";
String password = "user_password";
String newUrl = "jdbc:mysql://FE_IP:FE_PORT/demo?
useUnicode=true&characterEncoding=utf8&useTimezone=true&serverTimezone=Asia/Shanghai&useSSL=false&allowPublic
KeyRetrieval=true";
try {
    Connection myCon = DriverManager.getConnection(newUrl, user, password);
    Statement stmt = myCon.createStatement();
    ResultSet result = stmt.executeQuery("show databases");
    ResultSetMetaData metaData = result.getMetaData();
    int columnCount = metaData.getColumnCount();
    while (result.next()) {
        for (int i = 1; i <= columnCount; i++) {
            System.out.println(result.getObject(i));
        }
    }
}
```

```

} catch (SQLException e) {
    log.error("get JDBC connection exception.", e);
}

```

If you need to initially change session variables when connecting, you can use the following format:

```

jdbc:mysql://FE_IP:FE_PORT/demo?sessionVariables=key1=val1,key2=val2

```

DBeaver

Create a MySQL connection to Apache Doris:

The screenshot shows the 'Connect to a database' dialog box in DBeaver. The title bar says 'Connect to a database'. Inside, the 'Connection Settings' section is active, showing 'MySQL connection settings' with the MySQL logo. There are tabs for 'Main', 'Driver properties', 'SSH', and 'SSL'. A '+ Network configurations...' link is on the right. The 'Main' tab is selected, showing the following fields:

- Server**
 - Connect by: ☒ Host ☐ URL
 - URL:
 - Server Host: Port:
 - Database:
- Authentication (Database Native)**
 - Username:
 - Password: ☒ Save password
- Advanced**
 - Server Time Zone:
 - Local Client:

At the bottom, there are four buttons: '< Back', 'Next >', 'Cancel', and 'Finish'.

database-connect-dbeaver

Query in DBeaver:

query-in-dbeaver

Built-in Web UI of Doris

Doris FE has a built-in Web UI. It allows users to perform SQL queries and view other related information without the need to install the MySQL client

To access the Web UI, simply enter the URL in a web browser: `http://fe_ip:fe_port`, for example, `http://172.20.63.118:8030`. This will open the built-in Web console of Doris.

The built-in Web console is primarily intended for use by the root account of the cluster. By default, the root account password is empty after installation.

web-login-username-password

For example, you can execute the following command in the Playground to add a BE node.

```
ALTER SYSTEM ADD BACKEND "be_host_ip:heartbeat_service_port";
```

The screenshot shows the DORIS Playground web interface. At the top, there's a navigation bar with the DORIS logo, the word 'Playground', and several menu items: 'System', 'Log', 'QueryProfile', 'Session', and 'Configuration'. On the right side of the navigation bar, it shows 'EN' and 'root' with a dropdown arrow. Below the navigation bar, on the left, is a search bar and a list of databases: 'default_cluster: __internal_schema', 'default_cluster: information_schema', and 'default_cluster: mysql'. The main area is divided into two parts. The top part is the 'Editor' with a 'Format' button and a 'Clear the editor' link. It shows the 'Current Database: __internal_schema' and a list of two lines: a comment 'The ip and port here should be the ip and heartbeat_service_port of your BE node.' and the SQL command 'ALTER SYSTEM ADD BACKEND "172.20.63.118:9050";'. Below the editor is a blue 'Execute' button. The bottom part is the 'Results' section, which shows a green progress bar and the text 'Run successfully'. Below this, the executed SQL command is shown in a light blue box. At the bottom of the results section, it shows 'Execution Time: 18 ms'. At the very bottom of the interface, there's a pagination bar showing 'Total 0 items', '< 1 >', and '20 / page'.

Doris-Web-UI-Playground-en

For successful execution of statements that are not related to specific databases/tables in the Playground, it is necessary to randomly select a database from the left-hand database panel. This limitation will be removed later.

The current built-in web console cannot execute SET type SQL statements. Therefore, the web console does not support statements like SET PASSWORD FOR 'user' = PASSWORD('user_password').

Connecting by Arrow Flight SQL Protocol

Since Doris 2.1, a high-speed data link based on the Arrow Flight SQL protocol has been implemented, allowing SQL queries to rapidly retrieve large volumes of data from Doris in multiple languages. Arrow Flight SQL also provides a universal JDBC driver, supporting seamless interaction with databases that also follow the Arrow Flight SQL protocol. In some scenarios, performance can improve by up to a hundred times compared to data transfer solutions using MySQL Client or JDBC/ODBC drivers.

Implementation Principle

In Doris, query results are organized in columnar format as Blocks. In versions prior to 2.1, data could be transferred to the target client via MySQL Client or JDBC/ODBC drivers, but this required deserializing row-based Bytes into columnar format. By building a high-speed data transfer link based on Arrow Flight SQL, if the target client also supports Arrow columnar format, the entire transfer process avoids serialization and deserialization operations, completely eliminating the time and performance overhead associated with them.

Arrow_Flight_SQL

To install Apache Arrow, you can find detailed installation instructions in the official documentation [Apache Arrow](#). For more information on how Doris implements the Arrow Flight protocol, you can refer to [Doris support Arrow Flight SQL protocol](#).

Python Usage

Use Python's ADBC Driver to connect to Doris to achieve extremely fast data reading. The following steps use Python (version >= 3.9) ADBC Driver to perform a series of common database syntax operations, including DDL, DML, setting Session variables, and Show statements.

Install Library

The library is published on PyPI and can be easily installed in the following ways:

```
pip install adbc_driver_manager
pip install adbc_driver_flightsql
```

Import the following modules/libraries in the code to use the installed Library:

```
import adbc_driver_manager
import adbc_driver_flightsql
import adbc_driver_flightsql.dbapi as flight_sql

>>> print(adbc_driver_manager.__version__)
1.1.0
>>> print(adbc_driver_flightsql.__version__)
1.1.0
```

Connect to Doris

Create a client to interact with the Doris Arrow Flight SQL service. You need to provide Doris FE's Host, Arrow Flight Port, login username and password, and perform the following configuration. Modify the configuration parameters of Doris FE and BE:

- Modify `arrow_flight_sql_port` in `fe/conf/fe.conf` to an available port, such as 8070.
- Modify `arrow_flight_sql_port` in `be/conf/be.conf` to an available port, such as 8050.

Note: The `arrow_flight_sql_port` port number configured in `fe.conf` and `be.conf` is different

After modifying the configuration and restarting the cluster, searching for Arrow Flight SQL service is started in the `fe/log/fe.log` file indicates that the Arrow Flight Server of FE has been successfully started; searching for Arrow Flight Service bind to host in the `be/log/be.INFO` file indicates that the Arrow Flight Server of BE has been successfully started.

Assuming that the Arrow Flight SQL services of FE and BE in the Doris instance will run on ports 8070 and 8050 respectively, and the Doris username/password is "user"/"pass", the connection process is as follows:

```
conn = flight_sql.connect(uri="grpc://{FE_HOST}:{fe.conf:arrow_flight_sql_port}", db_kwargs={
    adbc_driver_manager.DatabaseOptions.USERNAME.value: "user",
    adbc_driver_manager.DatabaseOptions.PASSWORD.value: "pass",
})
cursor = conn.cursor()
```

After the connection is completed, the returned Cursor can be used to interact with Doris through SQL to perform operations such as creating tables, obtaining metadata, importing data, and querying.

Create a table and get metadata

Pass Query to the `cursor.execute()` function to execute the table creation and metadata acquisition operations:

```
cursor.execute("DROP DATABASE IF EXISTS arrow_flight_sql FORCE;")
print(cursor.fetchallarrow().to_pandas())
```

```

cursor.execute("create database arrow_flight_sql;")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("show databases;")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("use arrow_flight_sql;")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("""CREATE TABLE arrow_flight_sql_test
(
    k0 INT,
    k1 DOUBLE,
    K2 varchar(32) NULL DEFAULT "" COMMENT "",
    k3 DECIMAL(27,9) DEFAULT "0",
    k4 BIGINT NULL DEFAULT '10',
    k5 DATE,
)
DISTRIBUTED BY HASH(k5) BUCKETS 5
PROPERTIES("replication_num" = "1");""")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("show create table arrow_flight_sql_test;")
print(cursor.fetchallarrow().to_pandas())

```

If StatusResult returns 0, it means that the Query is executed successfully (the reason for this design is to be compatible with JDBC).

```

StatusResult
0          0

StatusResult
0          0

          Database
0      __internal_schema
1      arrow_flight_sql
..          ...
507      udf_auth_db

[508 rows x 1 columns]

StatusResult
0          0

StatusResult
0          0

          Table          Create Table
0  arrow_flight_sql_test  CREATE TABLE `arrow_flight_sql_test` (\n `k0`...

```

Import data

Execute INSERT INTO to import a small amount of test data into the created table:

```

cursor.execute("""INSERT INTO arrow_flight_sql_test VALUES
('0', 0.1, "ID", 0.0001, 999999999, '2023-10-21'),
('1', 0.20, "ID_1", 1.00000001, 0, '2023-10-21'),
('2', 3.4, "ID_1", 3.1, 123456, '2023-10-22'),
('3', 4, "ID", 4, 4, '2023-10-22'),

```

```
('4', 122345.54321, "ID", 122345.54321, 5, '2023-10-22');""")
print(cursor.fetchallarrow().to_pandas())
```

The following proves that the import was successful:

```
StatusResult
0          0
```

If you need to import large amounts of data into Doris, you can use pydoris to perform Stream Load.

Execute a query

Then query the table imported above, including operations such as aggregation, sorting, and Set Session Variable.

```
cursor.execute("select * from arrow_flight_sql_test order by k0;")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("set exec_mem_limit=2000;")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("show variables like \"%exec_mem_limit%\";")
print(cursor.fetchallarrow().to_pandas())

cursor.execute("select k5, sum(k1), count(1), avg(k3) from arrow_flight_sql_test group by k5;")
print(cursor.fetch_df())
```

The result is as follows:

```

k0      k1      K2      k3      k4      k5
0  0      0.10000  ID      0.000100000  9999999999  2023-10-21
1  1      0.20000  ID_1    1.000000010      0  2023-10-21
2  2      3.40000  ID_1    3.100000000    123456  2023-10-22
3  3      4.00000  ID      4.000000000      4  2023-10-22
4  4  122345.54321  ID  122345.543210000      5  2023-10-22

[5 rows x 6 columns]

StatusResult
0          0

Variable_name Value Default_Value Changed
0  exec_mem_limit  2000    2147483648      1

      k5  Nullable(Float64)_1  Int64_2  Nullable(Decimal(38, 9))_3
0  2023-10-22      122352.94321      3      40784.214403333
1  2023-10-21      0.30000      2      0.500050005

[2 rows x 5 columns]
```

Note: To fetch query results, you need to use `cursor.fetchallarrow()` to return the arrow format, or use `cursor.fetch_df()` to directly return the pandas dataframe, which will keep the data in column format. Do not use `cursor.fetchall()`, otherwise the column format data will be converted back to row format, which is essentially the same as using mysql-client. In fact, due to the extra column-to-row conversion operation on the client side, it may be slower than mysql-client.

Complete code

```
# Doris Arrow Flight SQL Test

# step 1, library is released on PyPI and can be easily installed.
# pip install adbc_driver_manager
# pip install adbc_driver_flightsql
import adbc_driver_manager
import adbc_driver_flightsql.dbapi as flight_sql

# step 2, create a client that interacts with the Doris Arrow Flight SQL service.
# Modify arrow_flight_sql_port in fe/conf/fe.conf to an available port, such as 8070.
# Modify arrow_flight_sql_port in be/conf/be.conf to an available port, such as 8050.
conn = flight_sql.connect(uri="grpc://{FE_HOST}:{fe.conf:arrow_flight_sql_port}", db_kwargs={
    adbc_driver_manager.DatabaseOptions.USERNAME.value: "root",
    adbc_driver_manager.DatabaseOptions.PASSWORD.value: "",
})
cursor = conn.cursor()

# interacting with Doris via SQL using Cursor
def execute(sql):
    print("\n### execute query: ###\n " + sql)
    cursor.execute(sql)
    print("### result: ###")
    print(cursor.fetchallarrow().to_pandas())

# step3, execute DDL statements, create database/table, show stmt.
execute("DROP DATABASE IF EXISTS arrow_flight_sql FORCE;")
execute("show databases;")
execute("create database arrow_flight_sql;")
execute("show databases;")
execute("use arrow_flight_sql;")
execute("""CREATE TABLE arrow_flight_sql_test
(
    k0 INT,
    k1 DOUBLE,
    k2 varchar(32) NULL DEFAULT "" COMMENT "",
    k3 DECIMAL(27,9) DEFAULT "0",
    k4 BIGINT NULL DEFAULT '10',
    k5 DATE,
)
DISTRIBUTED BY HASH(k5) BUCKETS 5
PROPERTIES("replication_num" = "1");""")
execute("show create table arrow_flight_sql_test;")

# step4, insert into
execute("""INSERT INTO arrow_flight_sql_test VALUES
('0', 0.1, "ID", 0.0001, 9999999999, '2023-10-21'),
('1', 0.20, "ID_1", 1.00000001, 0, '2023-10-21'),
('2', 3.4, "ID_1", 3.1, 123456, '2023-10-22'),
('3', 4, "ID", 4, 4, '2023-10-22'),
('4', 122345.54321, "ID", 122345.54321, 5, '2023-10-22');""")

# step5, execute queries, aggregation, sort, set session variable
execute("select * from arrow_flight_sql_test order by k0;")
execute("set exec_mem_limit=2000;")
execute("show variables like \"%exec_mem_limit%\";")
execute("select k5, sum(k1), count(1), avg(k3) from arrow_flight_sql_test group by k5;")

# step6, close cursor
cursor.close()
```

Jdbc Connector with Arrow Flight SQL

The open source JDBC driver of Arrow Flight SQL protocol is compatible with the standard JDBC API, which can be used by most BI tools to access Doris through JDBC and supports high-speed transmission of Apache Arrow data. The usage is similar to connecting to Doris through the JDBC driver of MySQL protocol. You only need to replace the jdbc:mysql protocol in the link URL with the jdbc:arrow-flight-sql protocol. The query results are still returned in the JDBC ResultSet data structure.

POM dependency:

```
<properties>
  <arrow.version>17.0.0</arrow.version>
</properties>
<dependencies>
  <dependency>
    <groupId>org.apache.arrow</groupId>
    <artifactId>flight-sql-jdbc-core</artifactId>
    <version>${arrow.version}</version>
  </dependency>
</dependencies>
```

Note: When using Java 9 or later, you must expose some JDK internal structures by adding `--add-opens=java.base/java.nio=ALL-UNNAMED` to the Java command, otherwise you may see some errors such as `module java.base does not "opens java.nio" to unnamed module` or `module java.base does not "opens java.nio" to org.apache.arrow.memory.core` or `java.lang.NoClassDefFoundError: Could not initialize class org.apache.arrow.memory.util.MemoryUtil (Internal; Prepare)`

```
# Directly on the command line
$ java --add-opens=java.base/java.nio=ALL-UNNAMED -jar ...
# Indirectly via environment variables
$ env _JAVA_OPTIONS="--add-opens=java.base/java.nio=ALL-UNNAMED" java -jar ...
```

If debugging in IntelliJ IDEA, you need to add `--add-opens=java.base/java.nio=ALL-UNNAMED` in Build and run of Run/Debug Configurations, refer to the picture below:

arrow-flight-sql-IntelliJ

The connection code example is as follows:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;

Class.forName("org.apache.arrow.driver.jdbc.ArrowFlightJdbcDriver");
String DB_URL = "jdbc:arrow-flight-sql://{FE_HOST}:{FE_CONF:arrow_flight_sql_port}?useServerPrepStmts=false"
    + "&cachePrepStmts=true&useSSL=false&useEncryption=false";
String USER = "root";
String PASS = "";

Connection conn = DriverManager.getConnection(DB_URL, USER, PASS);
Statement stmt = conn.createStatement();
ResultSet resultSet = stmt.executeQuery("select * from information_schema.tables;");
while (resultSet.next()) {
    System.out.println(resultSet.toString());
}

resultSet.close();
stmt.close();
conn.close();
```

Java Usage

In addition to using JDBC, similar to Python, JAVA can also create a Driver to read Doris and return data in Arrow format. The following are how to use AdbcDriver and JdbcDriver to connect to Doris Arrow Flight Server.

POM dependency:

```
<properties>
<adbc.version>0.15.0</adbc.version>
```

```

</properties>

<dependencies>
  <dependency>
    <groupId>org.apache.arrow.adbc</groupId>
    <artifactId>adbc-driver-jdbc</artifactId>
    <version>${adbc.version}</version>
  </dependency>
  <dependency>
    <groupId>org.apache.arrow.adbc</groupId>
    <artifactId>adbc-core</artifactId>
    <version>${adbc.version}</version>
  </dependency>
  <dependency>
    <groupId>org.apache.arrow.adbc</groupId>
    <artifactId>adbc-driver-manager</artifactId>
    <version>${adbc.version}</version>
  </dependency>
  <dependency>
    <groupId>org.apache.arrow.adbc</groupId>
    <artifactId>adbc-sql</artifactId>
    <version>${adbc.version}</version>
  </dependency>
  <dependency>
    <groupId>org.apache.arrow.adbc</groupId>
    <artifactId>adbc-driver-flight-sql</artifactId>
    <version>${adbc.version}</version>
  </dependency>
</dependencies>

```

ADBC Driver

The connection code example is as follows:

```

// 1. new driver
final BufferAllocator allocator = new RootAllocator();
FlightSqlDriver driver = new FlightSqlDriver(allocator);
Map<String, Object> parameters = new HashMap<>();
AdbcDriver.PARAM_URI.set(parameters, Location.forGrpcInsecure("{FE_HOST}",
{fe.conf:arrow_flight_sql_port}).getUri().toString());
AdbcDriver.PARAM_USERNAME.set(parameters, "root");
AdbcDriver.PARAM_PASSWORD.set(parameters, "");
AdbcDatabase adbcDatabase = driver.open(parameters);

// 2. new connection
AdbcConnection connection = adbcDatabase.connect();
AdbcStatement stmt = connection.createStatement();

// 3. execute query
stmt.setSqlQuery("select * from information_schema.tables;");
QueryResult queryResult = stmt.executeQuery();
ArrowReader reader = queryResult.getReader();

// 4. load result
List<String> result = new ArrayList<>();
while (reader.loadNextBatch()) {
  VectorSchemaRoot root = reader.getVectorSchemaRoot();
  String tsvString = root.contentToTSVString();
  result.add(tsvString);
}
System.out.printf("batchs %d\n", result.size());

```

```
// 5. close
reader.close();
queryResult.close();
stmt.close();
connection.close();
```

JDBC Driver

When using Java 9 or later, some JDK internals must be exposed by adding `--add-opens=java.base/java.nio=org.apache.arrow.memory.core,ALL-UNNAMED` to the java command:

```
# Directly on the command line
$ java --add-opens=java.base/java.nio=org.apache.arrow.memory.core,ALL-UNNAMED -jar ...
# Indirectly via environment variables
$ env _JAVA_OPTIONS="--add-opens=java.base/java.nio=org.apache.arrow.memory.core,ALL-UNNAMED" java -jar ...
```

Otherwise, you may see some errors such as module `java.base` does not "opens `java.nio`" to unnamed module or module `java.base` does not "opens `java.nio`" to `org.apache.arrow.memory.core` or `ava.lang.NoClassDefFoundError: Could not initialize class org.apache.arrow.memory.util.MemoryUtil (Internal; Prepare)`

If you debug in IntelliJ IDEA, you need to add `--add-opens=java.base/java.nio=ALL-UNNAMED` in Build and run of Run/Debug Configurations, refer to the picture below:

IntelliJ IDEA

The connection code example is as follows:

```

final Map<String, Object> parameters = new HashMap<>();
AdbcDriver.PARAM_URI.set(
    parameters, "jdbc:arrow-flight-sql://{FE_HOST}:{fe.conf:arrow_flight_sql_port}?
useServerPrepStmts=false&cachePrepStmts=true&useSSL=false&useEncryption=false");
AdbcDriver.PARAM_USERNAME.set(parameters, "root");
AdbcDriver.PARAM_PASSWORD.set(parameters, "");
try (
    BufferAllocator allocator = new RootAllocator();
    AdbcDatabase db = new JdbcDriver(allocator).open(parameters);
    AdbcConnection connection = db.connect();
    AdbcStatement stmt = connection.createStatement()
) {
    stmt.setSqlQuery("select * from information_schema.tables;");
    AdbcStatement.QueryResult queryResult = stmt.executeQuery();
    ArrowReader reader = queryResult.getReader();
    List<String> result = new ArrayList<>();
    while (reader.loadNextBatch()) {
        VectorSchemaRoot root = reader.getVectorSchemaRoot();
        String tsvString = root.contentToTSVString();
        result.add(tsvString);
    }
    long etime = System.currentTimeMillis();
    System.out.printf("batchs %d\n", result.size());

    reader.close();
    queryResult.close();
    stmt.close();
} catch (Exception e) {
    e.printStackTrace();
}

```

Choice of Jdbc and Java connection methods

[JDBC/Java Arrow Flight SQL Sample](#) is a JDBC/Java demo using Arrow FLight SQL. You can use it to test various connection methods for sending queries to Arrow Flight Server, helping you understand how to use Arrow FLight SQL and test performance. For expected execution results, see [Add Arrow Flight Sql demo for Java](#).

Compared with the traditional `jdbc:mysql` connection method, the performance test of the Arrow Flight SQL connection method of Jdbc and Java can be found in Section 6.2 of [GitHub Issue](#). Here are some usage suggestions based on the test conclusions.

1. For the above three Java Arrow Flight SQL connection methods, if the subsequent data analysis will be based on the row-based data format, then use `jdbc:arrow-flight-sql`, which will return data in the JDBC ResultSet format; if the subsequent data analysis can be based on the Arrow format or other column-based data formats, then use Flight AdbcDriver or Flight JdbcDriver to directly return data in the Arrow format, which will avoid row-column conversion and use the characteristics of Arrow to accelerate data parsing.
2. Whether parsing data in JDBC ResultSet or Arrow format, the time spent is longer than the time spent reading data. If the performance of Arrow Flight SQL is not as expected and the improvement is limited compared with `jdbc:mysql://`, you may want to analyze whether it takes too long to parse the data.
3. For all connection methods, JDK 17 reads data faster than JDK 1.8.

4. When reading a large amount of data, Arrow Flight SQL will use less memory than `jdbc:mysql://`, so if you are troubled by insufficient memory, you can also try Arrow Flight SQL.
5. In addition to the above three connection methods, you can also use the native `FlightClient` to connect to Arrow Flight Server, which can read multiple endpoints in parallel more flexibly. `FlightAdbcDriver` is also a link created based on `FlightClient`, which is simpler than using `FlightClient` directly.

Interaction with other big data components

Spark & Flink

Arrow Flight currently has no official plan to support Spark and Flink ([GitHub Issue](#)). Since version 24.0.0, Doris' own [Spark Connector](#) and [Flink Connector](#) have supported accessing Doris via Arrow Flight SQL, and it is expected that this will improve the reading performance several times.

The community previously referred to the open source [Spark-Flight-Connector](#) and used `FlightClient` in Spark to connect to Doris for testing. It was found that the data format conversion between Arrow and Doris Block is faster, which is 10 times the conversion speed between CSV format and Doris Block, and it has better support for complex types such as Map and Array. This is because the Arrow data format has a high compression rate and low network overhead during transmission. However, Doris Arrow Flight has not yet implemented multi-node parallel reading. It still aggregates query results to a BE node and returns them. For simple batch export of data, the performance may not be as fast as Doris Spark Connector, which supports Tablet-level parallel reading. If you want to use Arrow Flight SQL to connect to Doris in Spark, you can refer to the open-sourced [Spark-Flight-Connector](#) and [Dremio-Flight-Connector](#) to implement it yourself.

Support BI tools

Since Doris v2.1.8, BI tools such as DBeaver are supported to connect to Doris using the `arrow-flight-sql` protocol. For DBeaver's method of connecting to Doris using the `arrow-flight-sql` Driver, refer to: [how-to-use-jdbc-driver-with-dbeaver-client](#), [client-applications/clients/dbeaver/](#).

Extended Application

Multiple BEs return results in parallel

Doris will aggregate the results of a query on all BE nodes to one BE node by default. In MySQL/JDBC queries, FE will request query results from this aggregated data node. In Arrow Flight SQL queries, FE will wrap the IP/Port of this node in the Endpoint and return it to ADBC Client. ADBC Client will request the BE node corresponding to this Endpoint to pull data.

If the query is just a simple Select to pull data from Doris, without Join, Sort, Window Function and other operators with data Shuffle behavior, the query can be split according to Tablet granularity. Now Doris Spark/Flink Connector uses this method to implement parallel data reading, which is divided into two steps: 1. Execute `explain sql`, and the `ScanOperator` in the query plan returned by FE contains all Tablet ID Lists of Scan. 2. Split the original SQL into multiple SQLs based on the Tablet ID List above. Each SQL only reads part of the Tablet. The usage is similar to `SELECT * FROM t1 TABLET(10001,10002) limit 1000;`. The multiple SQLs after splitting can be executed in parallel. Refer to [Support select table sample](#).

If the outermost layer of the query is aggregation, the SQL is similar to `select k1, sum(k2) from xxx group by k1`. After Doris v3.0.4, execute `set enable_parallel_result_sink=true;` to allow each BE node of a query to return query results independently. After receiving the Endpoint list returned by FE, ADBC Client pulls results from multiple BE nodes in parallel. However, please note that when the aggregation result is very small, returning multiple BEs will increase the pressure on RPC. For specific implementation, please refer to [support parallel result sink](#). In theory, except for the outermost query which is sorted, other queries can support each BE node to return results in parallel, but there is no need for this convenience at present, and no further implementation has been made.

Multiple BEs share the same IP accessible from outside the cluster

If there is a Doris cluster, its FE nodes can be accessed from outside the cluster, and all its BE nodes can only be accessed from within the cluster. This is fine when using Mysql Client and JDBC to connect to Doris to execute queries, and the query results will be returned by the Doris FE node. However, using Arrow Flight SQL to connect to Doris will not work because the ADBC Client needs to connect to the Doris BE node to pull the query results, but the Doris BE node is not allowed to be accessed from outside the cluster.

In a production environment, it is often inconvenient to expose the Doris BE node outside the cluster. However, you can add a reverse proxy (such as Nginx) to all Doris BE nodes. When the client outside the cluster connects to Nginx, it will be randomly routed to a Doris BE node. By default, the Arrow Flight SQL query results will be randomly saved on a Doris BE node. If it is different from the Doris BE node randomly routed by Nginx, data forwarding is required within the Doris BE node.

Starting from Doris v2.1.8, you can configure `public_host` and `arrow_flight_sql_proxy_port` in `be.conf` of all Doris BE nodes to the IP and port shared by multiple Doris BE nodes and accessible outside the cluster. The query results can be correctly forwarded and returned to the ADBC Client.

```
public_host={nginx ip}
arrow_flight_sql_proxy_port={nginx port}
```

FAQ

1. Q: Error connection error: desc = "transport: Error while dialing: dial tcp <ip:arrow_flight_port>: i/o timeout".

A: If <ip:arrow_flight_port> in the error message is the IP and arrow-flight-port of the Doris FE node,

First check whether the arrow-flight-server of the Doris FE node is started normally. Searching for Arrow Flight SQL service is started in the `fe/log/fe.log` file indicates that the Arrow Flight Server of FE is started successfully.

If the arrow-flight-server of the Doris FE node is started normally, check whether the machine where the Client is located can ping the IP in the error message <ip:arrow_flight_port>. If it cannot be pinged, you need to open an externally accessible IP for the Doris FE node and redeploy the cluster.

A: If the <ip:arrow_flight_port> in the error message is the IP and arrow-flight-port of the Doris BE node.

First check whether the arrow-flight-server of the Doris BE node is started normally. Searching for Arrow Flight Service bind to host in the `be/log/be.INFO` file indicates that the Arrow Flight Server of BE is

started successfully.

If the arrow-flight-server of the Doris BE node starts normally, check whether the client machine can ping the IP in the <ip:arrow_flight_port> reported in the error message. If it cannot be ping, if it is known that the Doris BE node is in an intranet that cannot be accessed externally, the following two methods are used:

- Consider opening an externally accessible IP for each Doris BE node. Starting from Doris v2.1.8, you can configure public_host to this IP in the be.conf of this Doris BE node. Similarly, configure the public_host of all Doris BE nodes to the IP of the corresponding BE node that can be accessed by the client.
- Refer to the above section [Multiple BEs share the same IP that can be accessed externally by the cluster] to add a layer of reverse proxy for all Doris BE nodes.

If it is not clear whether Doris BE is completely in the intranet, check the connectivity between the client machine and other IPs of the machine where the Doris BE node is located. Execute ifconfig on the machine where the Doris BE node is located to return all the IPs of the current machine. One of the IPs should be the same as the IP in <ip:arrow_flight_port> and the same as the IP of the Doris BE node printed by show backends. ping the other IPs returned by ifconfig in turn. If the Doris BE node has an IP that can be accessed by the Client, refer to the above to configure this IP as public_host. If all IPs of the Doris BE node cannot be accessed by the Client, then the Doris BE node is completely in the intranet.

2. Q: When using JDBC or JAVA to connect to Arrow Flight SQL, an error message appears: module java.base does not "opens java.nio" to unnamed module or module java.base does not "opens java.nio" to org.apache.arrow.memory.core or java.lang.NoClassDefFoundError: Could not initialize class org.apache.arrow.memory.util.MemoryUtil (Internal; Prepare)

A: First check whether JAVA_OPTS_FOR_JDK_17 in fe/conf/fe.conf contains --add-opens=java.base/java.nio=ALL-UNNAMED. If not, add it. Then refer to the notes in [JDBC Connector with Arrow Flight SQL](#) above and add --add-opens=java.base/java.nio=ALL-UNNAMED in the Java command. If debugging in IntelliJ IDEA, you need to add --add-opens=java.base/java.nio=ALL-UNNAMED in Build and run of Run/Debug Configurations.

3. Q: The ARM environment reports an error get flight info statement failed, arrow flight schema timeout, TimeoutException: Waited 5000 milliseconds for io.grpc.stub.Client.

A: If the Linux kernel version is <= 4.19.90, you need to upgrade to 4.19.279 or above, or recompile Doris BE in the environment of the lower version of the Linux kernel. For specific compilation methods, refer to the document

Cause: This is because there is a compatibility issue between the old version of the Linux kernel and Arrow. cpp: arrow::RecordBatch::MakeEmpty() will get stuck when constructing Arrow Record Batch, causing Doris BE's Arrow Flight Server to fail to respond to Doris FE's Arrow Flight Server's RPC request within 5000ms, causing FE to return rpc timeout failed to Client. When Spark and Flink read Doris, they also convert the query results into Arrow Record Batch and return them, so the same problem exists.

The Linux kernel version of kylinv10 SP2 and SP3 is only 4.19.90-24.4.v2101.ky10.aarch64 at most. The kernel version cannot be upgraded further. Doris BE can only be recompiled on kylinv10. If the problem still exists after compiling Doris BE with the new version of ldb_toolchain, you can try to compile it with the lower version

of `ldb_toolchain v0.17`. If your ARM environment cannot connect to the external network, Huawei Cloud provides ARM + kylinv10, and Alibaba Cloud provides x86 + kylinv10

4. Q: Prepared statement passes parameters and reports errors.

A: Currently, `jdbc:arrow-flight-sql` and Java ADBC/JDBC Driver do not support prepared statement parameter passing. For example, `select * from xxx where id=?` will report an error `parameter ordinal 1 out of range`. This is a bug in Arrow Flight SQL ([GitHub Issue](#)).

5. Q: How to modify the batch size read by `jdbc:arrow-flight-sql` each time to improve performance in some scenarios.

A: By modifying `setTargetBatchSize` in the `makeJdbcConfig` method in the `org.apache.arrow.adbc.driver.jdbc.JdbcArrowReader` file, the default is 1024, and then saving the modified file to the local directory with the same path name, so as to overwrite the original file and take effect.

6. Q: ADBC v0.10, JDBC and Java ADBC/JDBC Driver do not support parallel reading.

A: The `stmt.executePartitioned()` method is not implemented. You can only use the native `FlightClient` to implement parallel reading of multiple endpoints, using the method `sqlClient=new FlightSqlClient, execute=sqlClient.execute(sql), endpoints=execute.getEndpoints(), for(FlightEndpoint endpoint: endpoints)`. In addition, the default `AdbcStatement` of ADBC V0.10 is actually `JdbcStatement`. After `executeQuery`, the row-format JDBC `ResultSet` is converted back to the Arrow column format. It is expected that Java ADBC will be fully functional by ADBC 1.0.0 [GitHub Issue](#).

7. Q: Specify the database name in the URL.

A: As of Arrow v15.0, Arrow JDBC Connector does not support specifying database name in URL. For example, specifying connection to test database in `jdbc:arrow-flight-sql://{FE_HOST}:{fe.conf:arrow_flight_sql_port}/test?useServerPrepStmts=false` is invalid, and you can only execute SQL use database manually. Arrow v18.0 supports specifying database name in URL, but there are still bugs in actual testing.

8. Q: Python ADBC prints Warning: Cannot disable autocommit; conn will not be DB-API 2.0 compliant.

A: Ignore this Warning when using Python. This is a problem with Python ADBC Client and will not affect queries.

9. Q: Python reports an error `grpc: received message larger than max (20748753 vs. 16777216)`.

A: Refer to [Python: grpc: received message larger than max \(20748753 vs. 16777216\) #2078](#) and add `adbc_driver_flightsql.DatabaseOptions.WITH_MAX_MSG_SIZE.value` in Database Option.

10. Q: Error invalid bearer token is reported.

A: Execute `SET PROPERTY FOR 'root' 'max_user_connections' = '10000'`; to change the current maximum number of connections for the current user to 10000; add `qe_max_connection=30000` and `arrow_flight_token_cache_size=8000` in `fe.conf` and restart FE.

The connection between the ADBC Client and the Arrow Flight Server is essentially a long link, which requires Auth Token, Connection, and Session to be cached on the Server. After the connection is created, it will not be

disconnected immediately at the end of a single query. The Client needs to send a close() request to clean it up, but in fact, the Client often does not send a close request, so the Auth Token, Connection, and Session will be saved on the Arrow Flight Server for a long time. By default, they will time out and disconnect after 3 days, or be eliminated according to LRU after the number of connections exceeds the limit of `arrow_flight_token_cache_size`.

As of Doris v2.1.8, Arrow Flight connections and Mysql/JDBC connections use the same connection limit, including the total number of connections of all FE users `qe_max_connection` and the number of connections of a single user `max_user_connections` in `UserProperty`. But the default `qe_max_connection` and `max_user_connections` are 1024 and 100 respectively. Arrow Flight SQL is often used to replace JDBC scenarios, but the JDBC connection will be released immediately after the query ends. Therefore, when using Arrow Flight SQL, the default connection limit of Doris is too small, which often causes the connection number to exceed the limit of `arrow_flight_token_cache_size` and the connections still in use to be eliminated.

11. Q: Using JDBC or JAVA to connect Arrow Flight SQL to read Datetime type returns a timestamp instead of a formatted time.

A: Using JDBC or JAVA to connect Arrow Flight SQL to read Datetime type requires converting the timestamp yourself, refer to [Add java parsing datetime type in arrow flight sql sample #48578](#). Using Python Arrow Flight SQL to read Datetime type returns the result of 2025-03-03 17:23:28Z, while JDBC or JAVA returns 1740993808.

12. Q: Using JDBC or Java JDBC Client to connect Arrow Flight SQL to read Array nested type returns an error Configuration does not provide a mapping for array column 2.

A: Refer to [sample/arrow-flight-sql](#) to use JAVA ADBC Client.

Python ADBC Client, JAVA ADBC Client, and Java JDBC DriverManager are all OK for reading Array nested types. Only when JDBC or Java JDBC Client is used to connect to Arrow Flight SQL, there is a problem. In fact, the compatibility of Arrow Flight JDBC is not guaranteed. It is not officially developed by Arrow, but by a third-party database company Dremio. Other compatibility issues have been found before, so it is recommended to use JAVA ADBC Client first.

2.1 Release Note

Doris Arrow Flight is not perfect in versions v2.1.4 and earlier, so it is recommended to upgrade before use.

v2.1.9

1. Fix the problem of Doris data serialization to Arrow. [Fix UT DataTypeSerDeArrowTest of Array/Map/Struct/Bitmap/HLL/Decimal256 types](#)
 - Failed to read Decimal256 type;
 - Subtle error in reading DatetimeV2 type;
 - Incorrect result in reading DateV2 type;
 - Error when reading IPV4/IPV6 type result is NULL;

2. Fix the problem that Doris Arrow Flight SQL query fails and returns empty result, without returning real error information. [Fix query result is empty and not return query error message](#)

v2.1.8

1. Support BI tools such as DBeaver to connect to Doris using the arrow-flight-sql protocol, and support the correct display of metadata trees. [Support arrow-flight-sql protocol getStreamCatalogs, getStreamSchemas, getStreamTables #46217](#).
2. When multiple BEs share the same IP that is accessible to the outside of the cluster, the query results can be correctly forwarded and returned to the ADBC Client. [Arrow flight server supports data forwarding when BE uses public vip](#)
3. Support multiple endpoints to read in parallel. [Arrow Flight support multiple endpoints](#)
4. Fix query error FE not found arrow flight schema. [Fix FE not found arrow flight schema](#)
5. Fix error BooleanBuilder::AppendValues when reading columns that allow NULL. [Fix Doris NULL column conversion to arrow batch](#)
6. Fix show processlist displays duplicate Connection IDs. [Fix arrow-flight-sql ConnectContext to use a unified ID #46284](#)
7. Fix the problem that the time zone is lost when reading Datetime and DatetimeV2 types, resulting in a datetime that is 8 hours less than the actual data. [Fix time zone issues and accuracy issues #38215](#)

v2.1.7

1. Fix frequent log printing Connection wait_timeout. [Fix kill timeout FlightSqlConnection and FlightSqlConnectProcessor close](#)
2. Fix Arrow Flight Bearer Token expiration from Cache. [Fix Arrow Flight bearer token cache evict after expired](#)

v2.1.6

1. Fix query error 0.0.0.0:xxx, connection refused. [Fix return result from FE Arrow Flight server error 0.0.0.0:xxx, connection refused](#)
2. Fix query error Reach limit of connections. [Fix exceed user property max connection cause Reach limit of connections #39127](#)

In previous versions, execute SET PROPERTY FOR 'root' 'max_user_connections' = '1024'; to modify the current maximum number of connections for the current user to 1024, which can be temporarily circumvented.

Because the previous version only limits the number of Arrow Flight connections to less than $qe_max_connection/2$, $qe_max_connection$ is the total number of connections for all fe users, the default is 1024, and does not limit the number of Arrow Flight connections for a single user to less than $max_user_connections$ in UserProperty, the default is 100, so when the number of Arrow Flight connections

exceeds the upper limit of the current user's connection number, an error `Reach limit of connections` will be reported, so the current user's `max_user_connections` needs to be increased.

For details of the problem, see: [Questions](#)

3. Add Conf `arrow_flight_result_sink_buffer_size_rows` to support modifying the ArrowBatch size of query results returned in a single time, the default is `4096 * 8`. [Add config arrow_flight_result_sink_buffer_size_rows](#)

v2.1.5

1. Fix the problem that Arrow Flight SQL query results are empty. [Fix arrow flight result sink #36827](#)

Doris v2.1.4 may report an error when reading large amounts of data. For details, see: [Questions](#)

3.0 Release Note

v3.0.5

1. Fix the problem of serializing Doris data to Arrow. [Fix UT DataTypeSerDeArrowTest of Array/Map/Struct/Bitmap/HLL/Decimal256 types](#)
 - Failed to read Decimal256 type;
 - Subtle error in reading DatetimeV2 type;
 - Incorrect result in reading DateV2 type;
 - Error when reading IPV4/IPV6 type result is NULL;

v3.0.4

1. Support DBeaver and other BI tools to connect to Doris using `arrow-flight-sql` protocol, and support correct display of metadata tree. [Support arrow-flight-sql protocol `getStreamCatalogs`, `getStreamSchemas`, `getStreamTables` #46217](#).
2. Support multiple endpoints to read in parallel. [Arrow Flight support multiple endpoints](#)
3. Fix the error `BooleanBuilder::AppendValues` when reading columns that allow NULL. [Fix Doris NULL column conversion to arrow batch](#)
4. Fix `show processlist` to display duplicate Connection IDs. [Fix arrow-flight-sql ConnectContext to use a unified ID #46284](#)
5. Fix Doris Arrow Flight SQL query failed and returned empty results, without returning real error information. [Fix query result is empty and not return query error message](#)

v3.0.3

1. Fix query error `0.0.0.0:xxx`, connection refused. [Fix return result from FE Arrow Flight server error 0.0.0.0:xxx, connection refused](#)

2. Fix query error Reach limit of connections. [Fix exceed user property max connection cause Reach limit of connections #39127](#)

In previous versions, execute `SET PROPERTY FOR 'root' 'max_user_connections' = '1024';` to modify the current maximum number of connections for the current user to 1024, which can be temporarily circumvented.

Because the previous version only limits the number of Arrow Flight connections to less than $qe_max_connection/2$, `qe_max_connection` is the total number of connections for all fe users, the default is 1024, and does not limit the number of Arrow Flight connections for a single user to less than `max_user_connections` in `UserProperty`, the default is 100, so when the number of Arrow Flight connections exceeds the upper limit of the current user's connection number, an error `Reach limit of connections` will be reported, so the current user's `max_user_connections` needs to be increased.

For details of the problem, see: [Questions](#)

3. Fix frequent printing of log `Connection wait_timeout`. [Fix kill timeout FlightSqlConnection and FlightSqlConnectProcessor close](#)
4. Fix Arrow Flight Bearer Token being eliminated from Cache after expiration. [Fix Arrow Flight bearer token cache evict after expired](#)
5. When multiple BEs share the same IP address accessible from outside the cluster, the query results can be correctly forwarded and returned to the ADBC Client. [Arrow flight server supports data forwarding when BE uses public vip](#)
6. Fix the query error `FE not found arrow flight schema`. [Fix FE not found arrow flight schema](#)
7. Fix the problem that the time zone is lost when reading `Datetime` and `DatetimeV2` types, resulting in a datetime that is 8 hours less than the actual data. [Fix time zone issues and accuracy issues #38215](#)

v3.0.2

1. Added Conf `arrow_flight_result_sink_buffer_size_rows` to support modifying the ArrowBatch size of query results returned in a single transaction, the default is $4096 * 8$. [Add config arrow_flight_result_sink_buffer_size_rows](#)

v3.0.1

1. Query results are missing, query result rows = actual number of rows / number of BEs [Fix get Schema failed when enable_parallel_result_sink is false #37779](#)

In Doris 3.0.0, if the outermost layer of the query is an aggregation, the SQL is similar to `select k1, sum(k2) from xxx group by k1`, you may encounter (query result rows = actual number of rows / number of BEs), which is a problem introduced by [support parallel result sink](#). In [Fix get Schema failed when enable_parallel_result_sink is false](#) is a temporary fix, which will be officially fixed after [Arrow Flight support multiple endpoints](#) supports parallel reading of multiple endpoints.

Overview | Table Design

Overview

Creating tables

Users can use the [CREATE TABLE](#) statement to create a table in Doris. You can also use the [CREATE TABLE LIKE](#) or [CREATE TABLE AS](#) clause to derive the table definition from another table.

Table name

In Doris, table names are case-sensitive by default. You can configure [lower_case_table_names](#) to make them case-insensitive during the initial cluster setup. The default maximum length for table names is 64 bytes, but you can change this by configuring [table_name_length_limit](#). It is not recommended to set this value too high. For syntax on creating tables, please refer to [CREATE TABLE](#).

Table property

In Doris, the CREATE TABLE statement can specify [table properties](#), including:

- **buckets**: Determines the distribution of data within the table.
- **storage_medium**: Controls the storage method for data, such as using HDD, SSD, or remote shared storage.
- **replication_num**: Controls the number of data replicas to ensure redundancy and reliability.
- **storage_policy**: Controls the migration strategy for cold and hot data separation storage.

These properties apply to partitions, meaning that after a partition is created, it will have its own properties. Modifying table properties will only affect partitions created in the future and will not affect existing partitions. For more information about table properties, refer to [ALTER TABLE PROPERTY](#). [Dynamic partitions](#) can have these properties set individually.

Notes

1. **Choose an appropriate data model**: The data model cannot be changed, so you need to select an appropriate [data model](#) when creating the table.
2. **Choose an appropriate number of buckets**: The number of buckets in an already created partition cannot be modified. You can modify the number of buckets by [replacing the partition](#), or you can modify the number of buckets for partitions that have not yet been created in dynamic partitions.
3. **Column addition operations**: Adding or removing VALUE columns is a lightweight operation that can be completed in seconds. Adding or removing KEY columns or modifying data types is a heavyweight operation, and the completion time depends on the amount of data. For large datasets, it is recommended to avoid adding or removing KEY columns or modifying data types.

4. **Optimize storage strategy:** You can use tiered storage to store cold data on HDD or S3/HDFS.

Table Model Overview

When creating a table in Doris, it is necessary to specify the table model to define how data is stored and managed. Doris provides three table models: the **Duplicate Key Model**, **Unique Key Model** and **Aggregate Key Model**, which cater to different application scenarios. Each model has corresponding mechanisms for data deduplication, aggregation, and updates. Choosing the appropriate table model helps achieve business objectives while ensuring flexibility and efficiency in data processing.

Table Model Classification

Doris supports three types of table models:

- [Duplicate Key Model](#): Allows the specified Key columns to be duplicated, and Doris's storage layer retains all written data. This model is suitable for situations where all original data records must be preserved.
- [Unique Key Model](#): Ensures that each row has a unique Key value, and guarantees that there are no duplicate rows for a given Key column. The Doris storage layer retains only the latest written data for each key, making this model suitable for scenarios that involve data updates.
- [Aggregate Key Model](#): Allows data to be aggregated based on the Key columns. The Doris storage layer retains aggregated data, reducing storage space and improving query performance. This model is typically used in situations where summary or aggregated information (such as totals or averages) is required.

After creating the table, the properties of the table model are confirmed and cannot be modified. Choosing the right model for the business is crucial:

- **Duplicate Key Model** is suitable for ad-hoc queries with any dimensions. Although it cannot leverage the benefits of pre-aggregation, it is not constrained by aggregation models and can take advantage of the columnar storage model (only reading relevant columns without needing to read all key columns).
- **Unique Key Model** is designed for scenarios where a unique key constraint is needed, ensuring the uniqueness of the key. However, it cannot utilize the query benefits brought by pre-aggregations such as ROLLUP.
- **Aggregate Key Model** can greatly reduce the data and computation required for aggregation queries through pre-aggregation, making it ideal for fixed-schema reporting queries. However, this model is not friendly to count (*) queries. Also, because the aggregation method for the Value columns is fixed, when performing other types of aggregation queries, semantic correctness must be considered.
- **Update partial columns**, please refer to the documentation for [Partial Column Updates in Unique Key Model](#) and [Partial Column Updates in Aggregate Model](#) for relevant usage advice.

Sort Key

In Doris, data is stored in a columnar format, and a table can be divided into Key columns and Value columns. The Key columns are used for grouping and sorting, while the Value columns are used for aggregation. Key columns can consist of one or more fields, and when creating a table, data is sorted and stored according to the columns of Aggregate Key, Unique Key, and Duplicate Key models.

Different table models require the specification of Key columns during table creation, each with a different significance: for the Duplicate Key model, the Key columns represent sorting, without any uniqueness constraints. In the Aggregate Key and Unique Key models, aggregation is performed based on the Key columns, which not only have sorting capabilities but also enforce uniqueness constraints.

Proper use of the Sort Key can provide the following benefits:

- **Accelerated Query Performance:** Sort keys help reduce the amount of data that needs to be scanned. For range queries or filtering queries, the sort key can directly locate the data. For queries that require sorting, the sort key can also accelerate the sorting process.
- **Data Compression Optimization:** Storing data in an ordered fashion based on the sort key improves compression efficiency, as similar data will be grouped together, significantly increasing the compression ratio and reducing storage space.
- **Reduced Deduplication Costs:** When using the Unique Key Model, the sort key allows Doris to perform deduplication more efficiently, ensuring data uniqueness.

When selecting a sort key, the following recommendations can be followed:

- The Key columns must come before all Value columns.
- Preferably choose integer types. This is because integer types are much more efficient in computation and lookup than strings.
- For selecting different lengths of integer types, follow the principle of choosing what is sufficient.
- For the length of VARCHAR and STRING types, follow the principle of choosing enough...

Table Model Comparison

	Duplicate Key Model	Unique Key Model	Aggregate Key Model
Key Column Uniqueness	Not Supported, Key columns can be duplicated	Supported	Supported
Synchronous Materialized View	Supported	Supported	Supported
Asynchronous Materialized View	Supported	Supported	Supported
UPDATE Statement	Not Supported	Supported	Not Supported
DELETE Statement	Partially Supported	Supported	Not Supported

	Duplicate Key Model	Unique Key Model	Aggregate Key Model
Full Row Update on Import	Not Supported	Supported	Not Supported
Partial Column Update on Import	Not Supported	Supported	Partially Supported

Duplicate Key Model

The **Duplicate Key Model** in Doris is the default table model, designed to store individual raw data records. The `Duplicate` Key specified during table creation determines the columns for sorting and storage, optimizing common queries. It is recommended to choose no more than three columns as the sort key. For more specific selection guidelines, refer to [Sort Key](#). The Duplicate Key Model has the following characteristics:

- **Preserving Raw Data:** The Duplicate Key Model retains all original data, making it ideal for storing and querying raw data. It is recommended for use cases requiring detailed data analysis to avoid data loss.
- **No Deduplication or Aggregation:** Unlike the Aggregate and Primary Key models, the Duplicate Key Model does not perform deduplication or aggregation, fully retaining identical records.
- **Flexible Data Querying:** The Duplicate Key Model retains all original data, enabling detailed extraction and aggregation across any dimension for metadata auditing and fine-grained analysis.

Use Cases

In the Duplicate Key Model, data is generally only appended, and old data is not updated. The Duplicate Key Model is ideal for scenarios that require full raw data:

- **Log Storage:** Used for storing various types of application logs, such as access logs, error logs, etc. Each piece of data needs to be detailed for future auditing and analysis.
- **User Behavior Data:** When analyzing user behavior, such as click data or user access paths, it is necessary to retain detailed user actions. This helps in building user profiles and conducting detailed analysis of behavior patterns.
- **Transaction Data:** For storing transaction or order data, once a transaction is completed, there is typically no need for data changes...

Table Creation Instructions

When creating a table, the **DUPLICATE KEY** keyword can be used to specify the Duplicate Key Model. The Duplicate Key table must specify the Key columns, which are used to sort the data during storage. In the following example, the Duplicate Key table stores log information and sorts the data based on the `log_time`, `log_type`, and `error_code` columns:

```
CREATE TABLE IF NOT EXISTS example_tbl_duplicate
(
  log_time      DATETIME      NOT NULL,
  log_type      INT           NOT NULL,
  error_code     INT,
  error_msg      VARCHAR(1024),
  op_id         BIGINT,
  op_time       DATETIME
)
DUPLICATE KEY(log_time, log_type, error_code)
DISTRIBUTED BY HASH(log_type) BUCKETS 10;
```

Data Insertion and Storage

In a Duplicate Key table, data is not deduplicated or aggregated; inserting data directly stores it. The Key columns in the Duplicate Key Model are used for sorting.

columnar_storage

In the example above, after inserting 2 rows into the initial 4 rows, the data is appended, resulting in a total of 6 rows.

```
-- 4 rows raw data
INSERT INTO example_tbl_duplicate VALUES
('2024-11-01 00:00:00', 2, 2, 'timeout', 12, '2024-11-01 01:00:00'),
('2024-11-02 00:00:00', 1, 2, 'success', 13, '2024-11-02 01:00:00'),
('2024-11-03 00:00:00', 2, 2, 'unknown', 13, '2024-11-03 01:00:00'),
('2024-11-04 00:00:00', 2, 2, 'unknown', 12, '2024-11-04 01:00:00');

-- insert into 2 rows
INSERT INTO example_tbl_duplicate VALUES
('2024-11-01 00:00:00', 2, 2, 'timeout', 12, '2024-11-01 01:00:00'),
('2024-11-01 00:00:00', 2, 2, 'unknown', 13, '2024-11-01 01:00:00');

-- check the rows of table
SELECT * FROM example_tbl_duplicate;
```

log_time	log_type	error_code	error_msg	op_id	op_time
2024-11-02 00:00:00	1	2	success	13	2024-11-02 01:00:00
2024-11-01 00:00:00	2	2	timeout	12	2024-11-01 01:00:00
2024-11-03 00:00:00	2	2	unknown	13	2024-11-03 01:00:00
2024-11-04 00:00:00	2	2	unknown	12	2024-11-04 01:00:00
2024-11-01 00:00:00	2	2	unknown	13	2024-11-01 01:00:00
2024-11-01 00:00:00	2	2	timeout	12	2024-11-01 01:00:00

Unique Key Model

When data updates are required, use the **Unique Key Model**. It guarantees the uniqueness of the Key columns so that new data overwrites existing records with matching keys, ensuring that only the most up-to-date records are maintained. This model is ideal for update scenarios, enabling unique-key-level updates during data insertion. The Unique Key Model has the following characteristics:

- **Unique Key UPSERT:** During insertion, records with duplicate keys are updated, while new keys are inserted.
- **Automatic Deduplication:** The model ensures key uniqueness and automatically deduplicates data based on the unique key.
- **Optimized for High-frequency Updates:** It efficiently handles high-frequency updates while balancing update and query performance.

Use Cases

- **High-frequency Data Updates:** In upstream OLTP databases, where dimension tables are frequently updated, the Unique Key Model can efficiently synchronize the upstream updated records and perform efficient UPSERT operations.
- **Efficient Data Deduplication:** In scenarios such as advertising campaigns or customer relationship management systems, where deduplication is required based on user IDs, the Unique Key Model ensures efficient deduplication.
- **Partial Columns Updates:** In scenarios such as in user profiling where dynamic tags change frequently, or in order consumption scenarios where the transaction status needs to be updated. The Unique Key Model's partial column update capability allows for changes to specific columns.

Implementation Methods

In Doris, the Unique Key Model has two implementation methods:

- **Merge-on-write:** Starting from version 1.2, the default implementation of the Unique Key Model in Doris is the merge-on-write mode. In this mode, data is immediately merged for the same Key upon writing, ensuring that the data storage state after each write is the final merged result of the unique key, and only the latest result is stored. Merge-on-write provides a good balance between query and write performance, avoiding the need to merge multiple versions of data during queries and ensuring predicate pushdown to the storage layer. The merge-on-write model is recommended for most scenarios.
- **Merge-on-read:** Prior to version 1.2, Doris's Unique Key Model defaulted to merge-on-read mode. In this mode, data is not merged upon writing but is appended incrementally, retaining multiple versions within Doris. During queries or Compaction, data is merged by the same Key version. Merge-on-read is suitable for write-heavy and read-light scenarios, but during queries, multiple versions must be merged, and predicates cannot be pushed down, which may affect query speed.

In Doris, there are two types of update semantics for the Unique Key Model:

- **Full Row Upsert:** The default update semantic for the Unique Key Model is **full row UPSERT**, i.e., UPDATE OR INSERT. If the Key of the row exists, it will be updated; if it does not exist, new data will be inserted. In the full row UPSERT semantic, even if the user inserts data into specific columns using INSERT INTO, Doris will fill in the missing columns with NULL values or default values during the planner stage.
- **Partial Column Upsert:** If users want to update specific fields, they need to use the merge-on-write implementation and enable partial column updates support via specific parameters. Please refer to the documentation on [Partial Column Updates](#).

Merge-on-write

Creating a Merge-on-write Table

To create a Unique Key table, use the UNIQUE KEY keyword. Enable merge-on-write mode by setting the enable_unique_key_merge_on_write attribute (default since Doris 2.1):

```
CREATE TABLE IF NOT EXISTS example_tbl_unique
(
  user_id      LARGEINT      NOT NULL,
  user_name    VARCHAR(50)    NOT NULL,
  city         VARCHAR(20),
  age          SMALLINT,
  sex          TINYINT
)
UNIQUE KEY(user_id, user_name)
DISTRIBUTED BY HASH(user_id) BUCKETS 10
PROPERTIES (
  "enable_unique_key_merge_on_write" = "true"
);
```

Merge-on-read

Creating a Merge-on-read Table

When creating a table, the UNIQUE KEY keyword can be used to specify a Unique Key table. The merge-on-read mode can be enabled by explicitly disabling the enable_unique_key_merge_on_write attribute. Before Doris version 2.1, the merge-on-read mode was enabled by default:

```
CREATE TABLE IF NOT EXISTS example_tbl_unique
(
  user_id      LARGEINT      NOT NULL,
  user_name    VARCHAR(50)    NOT NULL,
  city         VARCHAR(20),
  age          SMALLINT,
  sex          TINYINT
)
UNIQUE KEY(user_id, user_name)
DISTRIBUTED BY HASH(user_id) BUCKETS 10
PROPERTIES (
```

```
"enable_unique_key_merge_on_write" = "false"
);
```

Data Insertion and Storage

In a Unique Key table, the Key columns serve both for sorting and deduplication. New insertions overwrite existing records with matching keys.

Insert Data

user_id	user_name	city	age	sex
101	Tom	BJ	27	1
102	Jason	SH	28	1

Raw Data

user_id	user_name	city	age	sex
101	Tom	BJ	26	1
102	Jason	BJ	27	1
103	Juice	SH	20	2
104	Olivia	SZ	22	2

↓ Data Insert

→ Group by Key

101	Tom	BJ	26	1	raw
101	Tom	BJ	27	1	insert
102	Jason	BJ	27	1	raw
102	Jason	SH	28	1	insert
103	Juice	SH	20	2	raw
104	Olivia	SZ	22	2	raw

↓ Upsert by Key

user_id	user_name	city	age	sex
101	Tom	BJ	26 -> 27	1
102	Jason	BJ->SH	27 -> 28	1
103	Juice	SH	20	2
104	Olivia	SZ	22	2

unique-key-model-insert

As shown in the example, there were 4 rows of data in the original table. After inserting 2 new rows, the newly inserted rows are updated based on the unique key:

```
-- insert into raw data
INSERT INTO example_tbl_unique VALUES
(101, 'Tom', 'BJ', 26, 1),
(102, 'Jason', 'BJ', 27, 1),
(103, 'Juice', 'SH', 20, 2),
(104, 'Olivia', 'SZ', 22, 2);
```

```
-- insert into data to update by key
INSERT INTO example_tbl_unique VALUES
(101, 'Tom', 'BJ', 27, 1),
(102, 'Jason', 'SH', 28, 1);
```

```
-- check updated data
```

```
SELECT * FROM example_tbl_unique;
```

```
+-----+-----+-----+-----+-----+
| user_id | user_name | city | age | sex |
+-----+-----+-----+-----+-----+
| 101     | Tom      | BJ   | 27  | 1   |
| 102     | Jason    | SH   | 28  | 1   |
| 104     | Olivia   | SZ   | 22  | 2   |
| 103     | Juice    | SH   | 20  | 2   |
+-----+-----+-----+-----+-----+
```

Notes

- The implementation mode for Unique Key tables is fixed at creation and cannot be changed via schema alterations.
- Under full row UPSERT semantics, if specific columns are omitted during insertion, Doris fills them with NULL or default values during planning.
- For partial column upsert, enable merge-on-write mode with the appropriate parameters. Refer to [Partial Column Updates](#) for guidance.
- When using a Unique table, the partition key must be included in the Key columns to ensure data uniqueness.

Aggregate Model

Doris's **Aggregate Key Model** is designed to efficiently handle aggregation operations in large-scale data queries. By performing pre-aggregation on the data, it reduces redundancy in computations and improves query performance. The model stores only aggregated data, omitting raw data, which saves storage space and enhances query performance.

Use Cases

- **Summarizing Detailed Data:** The Aggregate Key Model is used in scenarios like e-commerce platforms evaluating monthly sales, financial risk control calculating customer transaction totals, or advertising campaigns analyzing total ad clicks, for multidimensional summarization of detailed data.
- **No Need to Query Raw Detailed Data:** For use cases such as dashboard reports or user transaction behavior analysis, where the raw data is stored in a data lake and does not need to be retained in the database, only the aggregated data is stored.

Principle

Each data import creates a version in the Aggregate Key Model, and during the **Compaction** stage, versions are merged. When querying, data is aggregated by the primary key:

- **Data Import Stage**
 - Data is imported into the aggregate key table in batches, with each batch creating a new version.
 - Within each version, data with the same aggregation keys is pre-aggregated (e.g., sum, count, etc.).
- **Background File Merging Stage (Compaction)**
 - Multiple batches generate multiple version files, which are periodically merged into a larger version file.
 - During the merge process, data with the same aggregation key is re-aggregated to reduce redundancy and optimize storage.
- **Query Stage**
 - During queries, the system aggregates data with the same aggregation key from all versions to ensure accurate results.
 - This process ensures that aggregation operations are performed efficiently, even with large data volumes. The aggregated results are optimized for fast querying, providing a significant performance improvement over raw data queries

Table Creation Instructions

When creating a table, the **AGGREGATE KEY** keyword can be used to specify the Aggregate Key Model. The Aggregate Key Model must specify Key columns, which are used to aggregate Value columns during storage.

```
CREATE TABLE IF NOT EXISTS example_tbl_agg
(
  user_id          LARGEINT    NOT NULL,
  load_dt          DATE        NOT NULL,
  city             VARCHAR(20),
  last_visit_dt    DATETIME    REPLACE DEFAULT "1970-01-01 00:00:00",
  cost             BIGINT      SUM DEFAULT "0",
  max_dwell        INT         MAX DEFAULT "0",
)
AGGREGATE KEY(user_id, load_dt, city)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

In the example above, a fact table for user information and access behavior is defined, where `user_id`, `load_dt`, and `city` are used as Key columns for aggregation. During data import, the Key columns are aggregated into one row, and the Value columns are aggregated according to the specified aggregation types.

The following types of dimension aggregation are supported in the Aggregate Key Model:

Aggregation Method	Description
SUM	Sum, accumulates multiple Value rows.
REPLACE	Replacement, the Value in the next batch replaces the previously inserted Value.
MAX	Retain the maximum value.
MIN	Retain the minimum value.
REPLACE_IF_NOT_NULL	Replace non-null values. Unlike REPLACE, null values are not replaced.
HLL_UNION	Aggregation method for HLL type columns, using the HyperLogLog algorithm.
BITMAP_UNION	Aggregation method for BITMAP type columns, performing bitmap union aggregation.

Tip:

If the aggregation methods above do not meet your business requirements, consider using the `agg_state` type.

Data Insertion and Storage

In the Aggregate Key table, data is aggregated based on the primary key. After data insertion, aggregation operations are completed.

Insert Data

user_id	load_dt	city	last_vist_dt	cost	max_dwell
101	11-01	BJ	10-30	20	10
102	11-01	BJ	10-30	10	30

Raw Data

user_id	load_dt	city	last_vist_dt	cost	max_dwell
101	11-01	BJ	10-29	10	20
102	10-30	BJ	10-29	20	20
101	10-30	BJ	10-28	5	40
101	10-30	SH	10-29	10	20

Data Insert

Group By Key

101	11-01	BJ	10-30	20	10	insert
101	11-01	BJ	10-29	10	20	raw
102	11-01	BJ	10-30	10	30	insert
102	10-30	BJ	10-29	20	20	raw
101	10-30	BJ	10-28	5	40	raw
104	10-30	SH	10-29	10	20	raw

result

user_id	load_dt	load_dt	last_vist_dt	cost	max_dwell
101	11-01	BJ	10-29 -> 10-30	10 + 20	max(10, 20)
102	11-01	BJ	10-30	10	30
102	10-30	BJ	10-29	20	20
101	10-30	BJ	10-28	5	40
104	10-30	SH	10-29	10	20

aggrate-key-model-insert

In the example above, there were originally 4 rows of data in the table. After inserting 2 rows, aggregation operations on the dimension columns are performed based on the Key columns:

```
-- 4 rows raw data
INSERT INTO example_tbl_agg VALUES
(101, '2024-11-01', 'BJ', '2024-10-29', 10, 20),
(102, '2024-10-30', 'BJ', '2024-10-29', 20, 20),
(101, '2024-10-30', 'BJ', '2024-10-28', 5, 40),
(101, '2024-10-30', 'SH', '2024-10-29', 10, 20);
```

```
-- insert into 2 rows
INSERT INTO example_tbl_agg VALUES
(101, '2024-11-01', 'BJ', '2024-10-30', 20, 10),
(102, '2024-11-01', 'BJ', '2024-10-30', 10, 30);
```

```
-- check the rows of table
SELECT * FROM example_tbl_agg;
```

user_id	load_date	city	last_visit_dt	cost	max_dwell
102	2024-10-30	BJ	2024-10-29 00:00:00	20	20
102	2024-11-01	BJ	2024-10-30 00:00:00	10	30
101	2024-10-30	BJ	2024-10-28 00:00:00	5	40
101	2024-10-30	SH	2024-10-29 00:00:00	10	20
101	2024-11-01	BJ	2024-10-30 00:00:00	30	20

AGG_STATE

::: Info Tips: AGG_STATE is an experimental feature and is recommended for use in development and testing environments.

AGG_STATE cannot be used as a Key column. The aggregation function's signature must be declared when creating the table. Users don't need to specify length or default values. The data storage size depends on the function implementation.

```

set enable_agg_state = true;
CREATE TABLE aggstate(
  k1    int    NULL,
  v1    int    SUM,
  v2    agg_state<group_concat(string)> generic
)
AGGREGATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 3;

```

In this case, `agg_state` is used to declare the data type as `agg_state`, and `sum/group_concat` is the signature of the aggregation function. Note that `agg_state` is a data type, just like `int`, `array`, or `string`. `agg_state` can only be used with combinators such as [state](#), [merge](#), or [union](#). `agg_state` represents the intermediate result of an aggregation function. For example, for the aggregation function `group_concat`, `agg_state` can represent the intermediate state of `group_concat('a', 'b', 'c')`, rather than the final result.

The `agg_state` type needs to be generated using the state function. For this table, you need to use `group_concat_state`:

```

insert into aggstate values(1, 1, group_concat_state('a'));
insert into aggstate values(1, 2, group_concat_state('b'));
insert into aggstate values(1, 3, group_concat_state('c'));
insert into aggstate values(2, 4, group_concat_state('d'));

```

The calculation method in the table is shown in the diagram below:

K1	V1	V2
1	sum(1, 2, 3)	group_concat('a', 'b', 'c')
2	sum(4)	group_concat('d')

state-func-group-concat-state-result-1

When querying the table, the [merge](#) operation can be used to merge multiple state values and return the final aggregation result. Since `group_concat` requires ordering, the result may be unstable.

```

select group_concat_merge(v2) from aggstate;
+-----+
| group_concat_merge(v2) |
+-----+
| d,c,b,a                |
+-----+

```

If you do not want the final aggregation result, you can use `union` to combine multiple intermediate aggregation results and generate a new intermediate result.

```

insert into aggstate select 3, sum(v1), group_concat_union(v2) from aggstate;

```

The calculations in the table are as follows:

K1	V1	V2
1	sum(1, 2, 3)	group_concat('a', 'b', 'c')
2	sum(4)	group_concat('d')
3	sum(1, 2, 3, 4)	group_concat('a', 'b', 'c', 'd')

state-func-group-concat-state-result-2

The query result is as follows:

```
mysql> select sum(v1), group_concat_merge(v2) from aggstate;
+-----+-----+
| sum(v1) | group_concat_merge(v2) |
+-----+-----+
|      20 | c,b,a,d,c,b,a,d      |
+-----+-----+

mysql> select sum(v1), group_concat_merge(v2) from aggstate where k1 != 2;
+-----+-----+
| sum(v1) | group_concat_merge(v2) |
+-----+-----+
|      16 | c,b,a,d,c,b,a        |
+-----+-----+
```

Usage Notes

Suggestions for column types

Suggestions for column types when creating a table:

1. The Key column should precede all Value columns.
2. Whenever possible, choose integer types. This is because the calculation and search efficiency of integer types are much higher than that of strings.
3. For selecting integer types of different lengths, follow the principle of sufficiency.
4. For the lengths of VARCHAR and STRING types, also follow the principle of sufficiency.

Limitations of aggregate model

This section is about the limitations of the Aggregate Model.

The Aggregate Model only presents the aggregated data. That means we have to ensure the presentation consistency of data that has not yet been aggregated (for example, two different import batches). The following provides further explanation with examples.

Suppose that you have the following table schema:

ColumnName	Type	AggregationType	Comment
user_id	LARGEINT		User ID
date	DATE		Date when the data are imported
cost	BIGINT	SUM	Total user consumption

Assume that there are two batches of data that have been imported into the storage engine as follows:

batch 1

user_id	date	cost
10001	2017-11-20	50
10002	2017-11-21	39

batch 2

user_id	date	cost
10001	2017-11-20	1
10001	2017-11-21	5
10003	2017-11-22	22

As you can see, data about User 10001 in these two import batches have not yet been aggregated. However, in order to ensure that users can only query the aggregated data as follows:

user_id	date	cost
10001	2017-11-20	51
10001	2017-11-21	5
10002	2017-11-21	39
10003	2017-11-22	22

We have added an aggregation operator to the query engine to ensure the presentation consistency of data.

In addition, on the aggregate column (Value), when executing aggregate class queries that are inconsistent with the aggregate type, please pay attention to the semantics. For example, in the example above, if you execute the following query:

```
SELECT MIN(cost) FROM table;
```

The result will be 5, not 1.

Meanwhile, this consistency guarantee could considerably reduce efficiency in some queries.

Take the basic count (*) query as an example:

```
SELECT COUNT(*) FROM table;
```

In other databases, such queries return results quickly. Because in actual implementation, the models can get the query result by counting rows and saving the statistics upon import, or by scanning only one certain column of data to get count value upon query, with very little overhead. But in Doris's Aggregation Model, the overhead of such queries is **large**.

For the previous example:

batch 1

user_id	date	cost
10001	2017-11-20	50
10002	2017-11-21	39

batch 2

user_id	date	cost
10001	2017-11-20	1
10001	2017-11-21	5
10003	2017-11-22	22

Since the final aggregation result is:

user_id	date	cost
10001	2017-11-20	51
10001	2017-11-21	5

user_id	date	cost
10002	2017-11-21	39
10003	2017-11-22	22

The correct result of `select count (*) from table;` should be **4**. But if the model only scans the `user_id` column and operates aggregation upon query, the final result will be **3** (10001, 10002, 10003). And if it does not operate aggregation, the final result will be **5** (a total of five rows in two batches). Apparently, both results are wrong.

In order to get the correct result, we must read both the `user_id` and `date` column, and **performs aggregation** when querying. That is to say, in the `count (*)` query, Doris must scan all AGGREGATE KEY columns (in this case, `user_id` and `date`) and aggregate them to get the semantically correct results. That means if there are many aggregated columns, `count (*)` queries could involve scanning large amounts of data.

Therefore, if you need to perform frequent `count (*)` queries, we recommend that you simulate `count (*)` by adding a column of value 1 and aggregation type SUM. In this way, the table schema in the previous example will be modified as follows:

ColumnName	Type	AggregationType	Comment
user ID	BIGINT		User ID
date	DATE		Date when the data are imported
Cost	BIGINT	SUM	Total user consumption
count	BIGINT	SUM	For count queries

The above adds a count column, the value of which will always be **1**, so the result of `select count (*) from table;` is equivalent to that of `select sum (count) from table;` The latter is much more efficient than the former. However, this method has its shortcomings, too. That is, it requires that users will not import rows with the same values in the AGGREGATE KEY columns. Otherwise, `select sum (count) from table;` can only express the number of rows of the originally imported data, instead of the semantics of `select count (*) from table;`

Another method is to add a count column of value 1 but aggregation type of REPLACE. Then `select sum (count) from table;` and `select count (*) from table;` could produce the same results. Moreover, this method does not require the absence of same AGGREGATE KEY columns in the import data.

MoW Unique Key Model

The Merge on Write implementation in the Unique Model does not impose the same limitation as the Aggregate Model. In Merge on Write, the model adds a `delete bitmap` for each imported rowset to mark the data being overwritten or deleted. With the previous example, after Batch 1 is imported, the data status will be as follows:

batch 1

user_id	date	cost	delete bit
10001	2017-11-20	50	false
10002	2017-11-21	39	false

After Batch 2 is imported, the duplicate rows in the first batch will be marked as deleted, and the status of the two batches of data is as follows

batch 1

user_id	date	cost	delete bit
10001	2017-11-20	50	true
10002	2017-11-21	39	false

batch 2

user_id	date	cost	delete bit
10001	2017-11-20	1	false
10001	2017-11-21	5	false
10003	2017-11-22	22	false

In queries, all data marked true in the delete bitmap will not be read, so there is no need for data aggregation. Since there are 4 valid rows in the above data, the query result should also be 4. This also enables minimum overhead since it only scans one column of data.

In the test environment, count(*) queries in Merge on Write of the Unique Model deliver 10 times higher performance than that of the Aggregate Model.

Duplicate model

The Duplicate Model does not impose the same limitation as the Aggregate Model because it does not involve aggregation semantics. For any columns, it can return the semantically correct results in count(*) queries.

Key columns

For the Duplicate, Aggregate, and Unique Models, the Key columns will be specified when the table is created, but there exist some differences: In the Duplicate Model, the Key columns of the table can be regarded as just “sorting columns”, but not unique identifiers. In Aggregate and Unique Models, the Key columns are both “sorting columns” and “unique identifier columns”.

Suggestions for choosing data model

Since the data model was established when the table was built, and **irrevocable thereafter, it is very important to select the appropriate data model.**

1. The Aggregate Model can greatly reduce the amount of data scanned and query computation by pre-aggregation. Thus, it is very suitable for report query scenarios with fixed patterns. But this model is unfriendly to count(*) queries. Meanwhile, since the aggregation method on the Value column is fixed, semantic correctness should be considered in other types of aggregation queries.
2. The Unique Model guarantees the uniqueness of primary key for scenarios requiring a unique primary key. The downside is that it cannot exploit the advantage brought by pre-aggregation such as ROLLUP

in queries. Users who have high-performance requirements for aggregate queries are recommended to use the newly added Merge on Write implementation since version 1.2.

3. The Duplicate Model is suitable for ad-hoc queries of any dimensions. Although it may not be able to take advantage of the pre-aggregation feature, it is not limited by what constrains the Aggregate Model and can give full play to the advantage of columnar storage (reading only the relevant columns, but not all Key columns).
4. If user need to use partial-update, please refer to document [partial-update](#)

Data Distribution Concept

In Doris, the core of **data distribution** is to efficiently map the rows of data written to the table onto various **data shards (Tablets)** in the underlying storage through reasonable partitioning and bucketing strategies. Through data distribution strategies, Doris can fully utilize the storage and computing capabilities of multiple nodes, thereby supporting efficient storage and querying of large-scale data.

Overview of Data Distribution

Data Writing

When writing data, Doris first allocates the rows of data to the corresponding partitions based on the table's partitioning strategy. Then, according to the bucketing strategy, the rows of data are further mapped to specific shards within the partition, determining the storage location of the data rows.

Query Execution

During query execution, Doris's optimizer will trim data based on partitioning and bucketing strategies to maximize the reduction of the scanning range. In cases involving JOIN or aggregation queries, data transfer across nodes (Shuffle) may occur. Reasonable partitioning and bucketing design can reduce Shuffle and fully utilize **Colocate Join** to optimize query performance.

Node and Storage Architecture

Node Types

A Doris cluster consists of the following two types of nodes:

- **FE Node (Frontend)**: Manages cluster metadata (such as tables and shards) and is responsible for SQL parsing and execution planning.
- **BE Node (Backend)**: Stores data and is responsible for executing computational tasks. The results from BE are aggregated and returned to FE, which then returns them to the user.

Data Shard (Tablet)

The data stored in the BE node is divided into shards, with each shard being the smallest unit of data management in Doris and the basic unit for data movement and replication.

Partitioning Strategy

Partitioning is the first layer of logical division for data organization, used to divide the data in the table into smaller subsets. Doris provides the following two **partition types** and three **partition modes**:

Partition Types

- **Range Partitioning:** Allocates data rows to corresponding partitions based on the value range of the partition column.
- **List Partitioning:** Allocates data rows to corresponding partitions based on specific values of the partition column.

Partition Modes

- **Manual Partitioning:** Users manually create partitions (e.g., specified during table creation or added via ALTER statements).
 - **Dynamic Partitioning:** The system automatically creates partitions based on time scheduling rules, but does not create partitions on demand when writing data.
 - **Automatic Partitioning:** The system automatically creates corresponding partitions as needed during data writing, but care should be taken to avoid generating too many partitions with dirty data.
-

Bucketing Strategy

Bucketing is the second layer of logical division for data organization, used to further divide data rows into smaller units within a partition. Doris supports the following two bucketing methods:

- **Hash Bucketing:** Distributes data rows evenly across shards by calculating the `crc32` hash value of the bucketing column and taking the modulus of the number of buckets.
 - **Random Bucketing:** Randomly allocates data rows to shards. When using Random bucketing, the `load_to_single_tablet` option can be used to optimize the quick writing of small-scale data.
-

Data Distribution Optimization

Colocate Join

For large tables that frequently require JOIN or aggregation queries, the **Colocate** strategy can be enabled to place data with the same bucketing column values on the same physical node, reducing data transfer across nodes and significantly improving query performance.

Partition Pruning

During queries, Doris can prune irrelevant partitions through filtering conditions, thereby reducing the data scanning range and lowering I/O costs.

Bucketing Parallelism

During queries, a reasonable number of buckets can fully utilize the computational and I/O resources of the machines.

Data Distribution Goals

1. **Uniform Data Distribution** Ensure that data is evenly distributed across all BE nodes to avoid data skew that could overload certain nodes, thereby improving overall system performance.
2. **Optimize Query Performance** Reasonable partition pruning can significantly reduce the amount of data scanned, a reasonable number of buckets can enhance computational parallelism, and effective use of COLOCATE can lower Shuffle costs, improving JOIN and aggregation query efficiency.
3. **Flexible Data Management**
 - Time-based partitioning to store cold data (HDD) and hot data (SSD).
 - Regularly delete historical partitions to free up storage space.
4. **Control Metadata Scale** The metadata for each shard is stored in both FE and BE, so it is necessary to reasonably control the number of shards. The empirical recommendation is:
 - For every 10 million shards, FE requires at least 100GB of memory.
 - The number of shards handled by a single BE should be less than 20,000.
5. **Optimize Write Throughput**
 - The number of buckets should be reasonably controlled (recommended < 128) to avoid degrading write performance.
 - The number of partitions written at one time should be appropriate (recommended to write a small number of partitions at a time).

By carefully designing and managing partitioning and bucketing strategies, Doris can efficiently support the storage and query processing of large-scale data, meeting various complex business needs.

Manual partitioning

Partition columns

- Partition columns can be specified as one or multiple columns, and the partition columns must be KEY columns.
- When `allow_partition_column_nullable` is set to true, Range partition supports the use of NULL partition columns. List Partition does not support NULL partition columns at all times.
- Regardless of the type of partition column, double quotes are required when writing partition values.
- There is theoretically no upper limit on the number of partitions. However, each table is limited to 4096 partitions by default. If you want to exceed this limit, you can modify the FE configuration parameters `max_multi_partition_num` and `max_dynamic_partition_num`.
- When creating a table without partitioning, the system will automatically generate a full-range partition with the same name as the table name. This partition is not visible to users and cannot be deleted or modified.
- Overlapping ranges are not allowed when creating partitions.

RANGE partitioning

Partition columns are usually time columns for convenient management of old and new data. RANGE partitioning supports column types such as DATE, DATETIME, TINYINT, SMALLINT, INT, BIGINT, and LARGEINT.

Partition information supports the following four writing methods:

- **FIXED RANGE:** This method defines the partition as a left-closed, right-open interval.

```
PARTITION BY RANGE(col1[, col2, ...])
(
  PARTITION partition_name1 VALUES [("k1-lower1", "k2-lower1", "k3-lower1",...), ("k1-upper1", "k2-upper1",
"k3-upper1", ...)],
  PARTITION partition_name2 VALUES [("k1-lower1-2", "k2-lower1-2", ...), ("k1-upper1-2", MAXVALUE, )
)
```

For example:

```
PARTITION BY RANGE(`date`)
(
  PARTITION `p201701` VALUES [("2017-01-01"), ("2017-02-01")),
  PARTITION `p201702` VALUES [("2017-02-01"), ("2017-03-01")),
  PARTITION `p201703` VALUES [("2017-03-01"), ("2017-04-01"))
)
```

- **LESS THAN:** This method only defines the upper bound of the partition. The lower bound is determined by the upper bound of the previous partition.

```

PARTITION BY RANGE(col1[, col2, ...])
(
    PARTITION partition_name1 VALUES LESS THAN MAXVALUE | ("value1", "value2", ...),
    PARTITION partition_name2 VALUES LESS THAN MAXVALUE | ("value1", "value2", ...)
)

```

For example:

```

PARTITION BY RANGE(`date`)
(
    PARTITION `p201701` VALUES LESS THAN ("2017-02-01"),
    PARTITION `p201702` VALUES LESS THAN ("2017-03-01"),
    PARTITION `p201703` VALUES LESS THAN ("2017-04-01")
)

PARTITION BY RANGE(`date`)
(
    PARTITION `p201701` VALUES LESS THAN ("2017-02-01"),
    PARTITION `p201702` VALUES LESS THAN ("2017-03-01"),
    PARTITION `p201703` VALUES LESS THAN ("2017-04-01")
    PARTITION `other` VALUES LESS THAN (MAXVALUE)
)

```

LIST partitioning

Partition columns based on LIST partitioning support data types such as BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, LARGEINT, DATE, DATETIME, CHAR, and VARCHAR. Partition values are enumerated values. Only when the data is one of the enumerated values of the target partition, the partition can be hit.

Partitions support specifying the enumerated values contained in each partition through VALUES IN (...).

For example:

```

PARTITION BY LIST(city)
(
    PARTITION `p_cn` VALUES IN ("Beijing", "Shanghai", "Hong Kong"),
    PARTITION `p_usa` VALUES IN ("New York", "San Francisco"),
    PARTITION `p_jp` VALUES IN ("Tokyo")
)

```

LIST partitioning also supports multi-column partitioning, for example:

```

PARTITION BY LIST(id, city)
(
    PARTITION p1_city VALUES IN (("1", "Beijing"), ("1", "Shanghai")),
    PARTITION p2_city VALUES IN (("2", "Beijing"), ("2", "Shanghai")),
    PARTITION p3_city VALUES IN (("3", "Beijing"), ("3", "Shanghai"))
)

```

NULL partitioning

Partition columns based on NULL partitioning must be not null columns by default. If you need to use null columns, set the session variable allow_partition_column_nullable to true. For LIST partitioning, the

NULL partitioning is supported, while for RANGE partitioning, null values will be assigned to the less than partition. The columns are as follows:

LIST partitioning

```
mysql> create table null_list(
  -> k0 varchar null
  -> )
  -> partition by list (k0)
  -> (
  -> PARTITION pX values in ((NULL))
  -> )
  -> DISTRIBUTED BY HASH(`k0`) BUCKETS 1
  -> properties("replication_num" = "1");
Query OK, 0 rows affected (0.11 sec)

mysql> insert into null_list values (null);
Query OK, 1 row affected (0.19 sec)

mysql> select * from null_list;
+-----+
| k0    |
+-----+
| NULL  |
+-----+
1 row in set (0.18 sec)
```

RANGE partitioning with the less than partition

```
mysql> create table null_range(
  -> k0 int null
  -> )
  -> partition by range (k0)
  -> (
  -> PARTITION p10 values less than (10),
  -> PARTITION p100 values less than (100),
  -> PARTITION pMAX values less than (maxvalue)
  -> )
  -> DISTRIBUTED BY HASH(`k0`) BUCKETS 1
  -> properties("replication_num" = "1");
Query OK, 0 rows affected (0.12 sec)

mysql> insert into null_range values (null);
Query OK, 1 row affected (0.19 sec)

mysql> select * from null_range partition(p10);
+-----+
| k0    |
+-----+
| NULL  |
+-----+
1 row in set (0.18 sec)
```

RANGE partitioning without the less than partition

```
mysql> create table null_range2(
  -> k0 int null
  -> )
  -> partition by range (k0)
  -> (
```

```
-> PARTITION p200 values [("100"), ("200")]
-> )
-> DISTRIBUTED BY HASH(`k0`) BUCKETS 1
-> properties("replication_num" = "1");
Query OK, 0 rows affected (0.13 sec)

mysql> insert into null_range2 values (null);
ERROR 5025 (HY000): Insert has filtered data in strict mode, tracking_url=.....
```

Dynamic Partitioning

Dynamic partitioning will add and remove partitions in a rolling manner according to predefined rules, thereby managing the lifecycle of table partitions (TTL) and reducing data storage pressure. In scenarios such as log management and time-series data management, dynamic partitioning can typically be used to roll-delete expired data.

The diagram below illustrates lifecycle management using dynamic partitioning, with the following rules specified:

- The dynamic partition scheduling unit `dynamic_partition.time_unit` is set to `DAY`, organizing partitions by day;
- The dynamic partition start offset `dynamic_partition.start` is set to `-1`, retaining the partition from one day ago;
- The dynamic partition end offset `dynamic_partition.end` is set to `2`, retaining partitions for the next two days.

According to the above rules, as time progresses, a total of 4 partitions will always be retained: the partition from the past day, the current day partition, and the partitions for the next two days.

dynamic-partition

Usage Restrictions

When using dynamic partitioning, the following rules must be followed:

- Dynamic partitioning will fail when used simultaneously with Cross-Cluster Replication (CCR).
- Dynamic partitioning only supports Range type partitions on DATE/DATETIME columns.
- Dynamic partitioning only supports a single partition key.

Creating Dynamic Partitions

When creating a table, you can create a dynamic partitioned table by specifying the `dynamic_partition` property.

```
CREATE TABLE test_dynamic_partition(  
    order_id    BIGINT,  
    create_dt   DATE,  
    username    VARCHAR(20)  
)  
DUPLICATE KEY(order_id)  
PARTITION BY RANGE(create_dt) ()  
DISTRIBUTED BY HASH(order_id) BUCKETS 10  
PROPERTIES(  
    "dynamic_partition.enable" = "true",  
    "dynamic_partition.time_unit" = "DAY",  
    "dynamic_partition.start" = "-1",  
    "dynamic_partition.end" = "2",  
    "dynamic_partition.prefix" = "p",  
    "dynamic_partition.create_history_partition" = "true"  
);
```

In the example above, a dynamic partitioned table was created with the following specifications.

For detailed `dynamic_partition` parameters, refer to [Dynamic Partition Parameter Description](#).

Managing Dynamic Partitions

Modifying Dynamic Partition Properties

Tip:

When using the `ALTER TABLE` statement to modify dynamic partitioning, the changes will not take effect immediately. The dynamic partitions will be polled and checked at intervals specified by the `dynamic_partition_check_interval_seconds` parameter to complete the necessary partition creation and deletion operations.

In the example below, the `ALTER TABLE` statement is used to modify a non-dynamic partitioned table to a dynamic partitioned table:

```
CREATE TABLE test_partition(  
    order_id    BIGINT,  
    create_dt   DATE,  
    username    VARCHAR(20)  
)  
DUPLICATE KEY(order_id)  
PARTITION BY RANGE(create_dt) ()  
DISTRIBUTED BY HASH(order_id) BUCKETS 10;  
  
ALTER TABLE test_partition SET (  
    "dynamic_partition.enable" = "true",  
    "dynamic_partition.time_unit" = "DAY",  
    "dynamic_partition.start" = "-1",  
    "dynamic_partition.end" = "2",
```

```
"dynamic_partition.prefix" = "p",
"dynamic_partition.create_history_partition" = "true"
);
```

查看动态分区调度情况

通过 [SHOW-DYNAMIC-PARTITION](#) 可以查看当前数据库下，所有动态分区表的调度情况：

```
SHOW DYNAMIC PARTITION TABLES;
```

TableName	Enable	TimeUnit	Start	End	Prefix	Buckets	StartOf	LastUpdateTime	LastSchedulerTime	State	LastCreatePartitionMsg	LastDropPartitionMsg	ReservedHistoryPeriods
d3	true	WEEK	-3	3	p	1	MONDAY	N/A	2020-05-25 14:29:24	NORMAL	N/A	[2021-12-01,2021-12-31]	
d5	true	DAY	-7	3	p	32	N/A	N/A	2020-05-25 14:29:24	NORMAL	N/A	NULL

7 rows in set (0.02 sec)

Historical Partition Management

When specifying the number of dynamic partitions using the start and end attributes, historical partitions are not created all at once to avoid long waiting times. Only partitions after the current time are created. If you need to create all partitions at once, you must enable the create_history_partition parameter.

For example, if the current date is 2024-10-11 and you set start = -2 and end = 2:

- If create_history_partition = true is specified, all partitions are created immediately, resulting in five partitions: [10-09, 10-13].
- If create_history_partition = false is specified, only partitions from 10-11 onwards are created, resulting in three partitions: [10-11, 10-13].

Dynamic Partition Parameter Description

Dynamic Partition Property Parameters

Dynamic partition rule parameters are prefixed with dynamic_partition and can be set with the following rule parameters:

Parameter	Description
dynamic_partition.enable	NWhether to enable the dynamic partition feature. Can be set to TRUE or FALSE. If other required dynamic partition parameters are specified, it defaults to TRUE.
dynamic_partition.time_unit	YThe unit of dynamic partition scheduling. Can be set to HOUR, DAY, WEEK, MONTH, or YEAR, indicating partition creation or deletion by hour, day, week, month, or year respectively.
dynamic_partition.start	NThe starting offset for dynamic partitions, which is a negative number. The default value is -2147483648, meaning historical partitions are not deleted. Depending on the time_unit attribute, partitions before this offset based on the current day (week/month) will be deleted. Whether historical partitions after this offset up to the current time are created depends on dynamic_partition.create_history_partition.
dynamic_partition.end	YThe ending offset for dynamic partitions, which is a positive number. Depending on the time_unit attribute, partitions within the specified range ahead of the current day (week/month) are created in advance.
dynamic_partition.prefix	YThe prefix for dynamically created partition names.
dynamic_partition.buckets	NThe number of buckets corresponding to dynamically created partitions. Setting this parameter will override the number of buckets specified in DISTRIBUTED.
dynamic_partition.replication_num	NThe number of replicas corresponding to dynamically created partitions. If not specified, it defaults to the number of replicas specified when the table was created.
dynamic_partition.create_history_partition	NDefaults to false. When set to true, Doris will automatically create all partitions according to the rules below. Additionally, the parameter max_dynamic_partition_num will limit the total number of partitions to avoid creating too many partitions at once. If the number of partitions to be created exceeds the max_dynamic_partition_num value, the operation will be prohibited. This parameter does not take effect if the start attribute is not specified.
dynamic_partition.history_partition_num	NWhen create_history_partition is set to true, this parameter specifies the number of historical partitions to create. The default value is -1, meaning it is not set. This variable functions the same as dynamic_partition.start, and it is recommended to set only one of them simultaneously.

Parameter	Description
dynamic_partition.start_day_of_week	When time_unit is set to WEEK, this parameter specifies the starting day of the week. Values range from 1 to 7, where 1 represents Monday and 7 represents Sunday. The default is 1, meaning the week starts on Monday.
dynamic_partition.start_day_of_month	When time_unit is set to MONTH, this parameter specifies the starting date of the month. Values range from 1 to 28, where 1 represents the first day of the month and 28 represents the 28th day. The default is 1, meaning the month starts on the first day. Starting on the 29th, 30th, or 31st is not supported to avoid ambiguities caused by leap years or leap months.
dynamic_partition.reserved_history_periods	The time range of historical partitions that need to be retained. When dynamic_partition.time_unit is set to "DAY/WEEK/MONTH/YEAR", it should be set in the format [yyyy-MM-dd, yyyy-MM-dd], [...]. When dynamic_partition.time_unit is set to "HOUR", it should be set in the format [yyyy-MM-dd HH:mm:ss, yyyy-MM-dd HH:mm:ss], [...]. If not set, it defaults to "NULL".
dynamic_partition.time_zone	The time zone for dynamic partitioning, which defaults to the server's system time zone, such as Asia/Shanghai. For more time zone settings, refer to Time Zone Management .

FE Configuration Parameters

Dynamic partition parameter configurations in FE can be modified in the FE configuration file or via the ADMIN SET FRONTEND CONFIG command:

Parameter	Default Value	Description
dynamic_partition_enable	false	Whether to enable Doris's dynamic partition feature. This parameter only affects partition operations of dynamic partition tables and does not affect regular tables.
dynamic_partition_check_interval_seconds	600	The execution frequency of the dynamic partition thread, in seconds.
max_dynamic_partition_num	500	Limits the maximum number of partitions that can be created when creating a dynamic partition table to avoid creating too many partitions at once.

Dynamic Partition Best Practices

Example 1: Partition by day, retain partitions for the past 7 days and the current day, and pre-create partitions for the next 3 days.

```

CREATE TABLE tbl1 (
  order_id    BIGINT,
  create_dt   DATE,
  username    VARCHAR(20)
)
PARTITION BY RANGE(create_dt) ()
DISTRIBUTED BY HASH(create_dt)
PROPERTIES (
  "dynamic_partition.enable" = "true",
  "dynamic_partition.time_unit" = "DAY",
  "dynamic_partition.start" = "-7",
  "dynamic_partition.end" = "3",
  "dynamic_partition.prefix" = "p",
  "dynamic_partition.buckets" = "32"
);

```

Example 2: Partition by month, do not delete historical partitions, and pre-create partitions for the next 2 months. Additionally, set the starting day to the 3rd of each month.

```

CREATE TABLE tbl1 (
  order_id    BIGINT,
  create_dt   DATE,
  username    VARCHAR(20)
)
PARTITION BY RANGE(create_dt) ()
DISTRIBUTED BY HASH(create_dt)
PROPERTIES (
  "dynamic_partition.enable" = "true",
  "dynamic_partition.time_unit" = "MONTH",
  "dynamic_partition.end" = "2",
  "dynamic_partition.prefix" = "p",
  "dynamic_partition.buckets" = "8",
  "dynamic_partition.start_day_of_month" = "3"
);

```

Example 3: Partition by day, retain partitions for the past 10 days and the next 10 days, and retain historical data during the periods [2020-06-01, 2020-06-20] and [2020-10-31, 2020-11-15].

```

CREATE TABLE tbl1 (
  order_id    BIGINT,
  create_dt   DATE,
  username    VARCHAR(20)
)
PARTITION BY RANGE(create_dt) ()
DISTRIBUTED BY HASH(create_dt)
PROPERTIES (
  "dynamic_partition.enable" = "true",
  "dynamic_partition.time_unit" = "DAY",
  "dynamic_partition.start" = "-10",
  "dynamic_partition.end" = "10",
  "dynamic_partition.prefix" = "p",
  "dynamic_partition.buckets" = "8",
  "dynamic_partition.reserved_history_periods"="[2020-06-01,2020-06-20],[2020-10-31,2020-11-15]"
);

```

Auto Partition

Application scenario

The Auto Partition feature supports automatic detection of whether the corresponding partition exists during the data import process. If it does not exist, the partition will be created automatically and imported normally.

The auto partition function mainly solves the problem that the user expects to partition the table based on a certain column, but the data distribution of the column is scattered or unpredictable, so it is difficult to accurately create the required partitions when building or adjusting the structure of the table, or the number of partitions is so large that it is too cumbersome to create them manually.

Take the time type partition column as an example, in dynamic partitioning, we support the automatic creation of new partitions to accommodate real-time data at specific time periods. For real-time user behavior logs and other scenarios, this feature basically meets the requirements. However, in more complex scenarios, such as dealing with non-real-time data, the partition column is independent of the current system time and contains a large number of discrete values. At this time, to improve efficiency we want to partition the data based on this column, but the data may actually involve the partition can not be grasped in advance, or the expected number of required partitions is too large. In this case, dynamic partitioning or manually created partitions cannot meet our needs, while Auto Partition covers such needs.

Suppose the table DDL is as follows:

```
CREATE TABLE `DAILY_TRADE_VALUE`
(
  `TRADE_DATE`          datev2 NOT NULL COMMENT 'TRADE_DATE',
  `TRADE_ID`            varchar(40) NOT NULL COMMENT 'TRADE_ID',
  .....
)
UNIQUE KEY(`TRADE_DATE`, `TRADE_ID`)
PARTITION BY RANGE(`TRADE_DATE`)
(
  PARTITION p_2000 VALUES [('2000-01-01'), ('2001-01-01')),
  PARTITION p_2001 VALUES [('2001-01-01'), ('2002-01-01')),
  PARTITION p_2002 VALUES [('2002-01-01'), ('2003-01-01')),
  PARTITION p_2003 VALUES [('2003-01-01'), ('2004-01-01')),
  PARTITION p_2004 VALUES [('2004-01-01'), ('2005-01-01')),
  PARTITION p_2005 VALUES [('2005-01-01'), ('2006-01-01')),
  PARTITION p_2006 VALUES [('2006-01-01'), ('2007-01-01')),
  PARTITION p_2007 VALUES [('2007-01-01'), ('2008-01-01')),
  PARTITION p_2008 VALUES [('2008-01-01'), ('2009-01-01')),
  PARTITION p_2009 VALUES [('2009-01-01'), ('2010-01-01')),
  PARTITION p_2010 VALUES [('2010-01-01'), ('2011-01-01')),
  PARTITION p_2011 VALUES [('2011-01-01'), ('2012-01-01')),
  PARTITION p_2012 VALUES [('2012-01-01'), ('2013-01-01')),
  PARTITION p_2013 VALUES [('2013-01-01'), ('2014-01-01')),
  PARTITION p_2014 VALUES [('2014-01-01'), ('2015-01-01')),
  PARTITION p_2015 VALUES [('2015-01-01'), ('2016-01-01')),
  PARTITION p_2016 VALUES [('2016-01-01'), ('2017-01-01')),
  PARTITION p_2017 VALUES [('2017-01-01'), ('2018-01-01')),
  PARTITION p_2018 VALUES [('2018-01-01'), ('2019-01-01')),
  PARTITION p_2019 VALUES [('2019-01-01'), ('2020-01-01')),
  PARTITION p_2020 VALUES [('2020-01-01'), ('2021-01-01')),
  PARTITION p_2021 VALUES [('2021-01-01'), ('2022-01-01'))
```

```

)
DISTRIBUTED BY HASH(`TRADE_DATE`) BUCKETS 10
PROPERTIES (
  "replication_num" = "1"
);

```

The table stores a large amount of business history data, partitioned based on the date the transaction occurred. As you can see when building the table, we need to manually create the partitions in advance. If the data range of the partitioned columns changes, for example, 2022 is added to the above table, we need to create a partition by [ALTER-TABLE-PARTITION](#) to make changes to the table partition. If such partitions need to be changed, or subdivided at a finer level of granularity, it is very tedious to modify them. At this point we can rewrite the table DDL using Auto Partition.

Syntax

When creating a table, use the following syntax to populate the `partitions_definition` section in the [CREATE-TABLE](#) statement.

1. AUTO RANGE PARTITION:

```

AUTO PARTITION BY RANGE(<partition_expr>)
<origin_partitions_definition>

```

where

```

partition_expr ::= date_trunc ( <partition_column>, '<interval>' )

```

2. AUTO LIST PARTITION:

```

AUTO PARTITION BY LIST(`partition_col1` [, `partition_col2`, ...])
<origin_partitions_definition>

```

Sample

1. AUTO RANGE PARTITION

```

CREATE TABLE `date_table` (
  `TIME_STAMP` datev2 NOT NULL
) ENGINE=OLAP
DUPLICATE KEY(`TIME_STAMP`)
AUTO PARTITION BY RANGE (date_trunc(`TIME_STAMP`, 'month'))
(
)
DISTRIBUTED BY HASH(`TIME_STAMP`) BUCKETS 10
PROPERTIES (
  "replication_allocation" = "tag.location.default: 1"
);

```

2. AUTO LIST PARTITION

```
CREATE TABLE `str_table` (
  `str` varchar not null
) ENGINE=OLAP
DUPLICATE KEY(`str`)
AUTO PARTITION BY LIST (`str`)
()
DISTRIBUTED BY HASH(`str`) BUCKETS 10
PROPERTIES (
  "replication_allocation" = "tag.location.default: 1"
);
```

List Auto Partition supports multiple partition columns, which are written in the same way as normal List Partition: `AUTO PARTITION BY LIST (`col1`, `col2`, ...)`

Constraints

- In auto List Partition, the partition name length **must not exceed 50 characters**. This length is derived from the concatenation and escape of contents of partition columns on corresponding data rows, so the actual allowed length may be shorter.
- In auto Range Partition, the partition function only supports `date_trunc`, and the partition column supports only `DATE` or `DATETIME` types.
- In auto List Partition, function calls are not supported, and the partition column supports `BOOLEAN`, `TINYINT`, `SMALLINT`, `INT`, `BIGINT`, `LARGEINT`, `DATE`, `DATETIME`, `CHAR`, `VARCHAR` data types, with partition values being enumeration values.
- In auto List Partition, for every existing value in the partition column that does not correspond to a partition, a new independent partition will be created.

NULL value partition

When the session variable `allow_partition_column_nullable` is enabled:

- For Auto List Partition, the corresponding NULL value partition will be created automatically:

```
create table auto_null_list(
  k0 varchar null
)
auto partition by list (k0)
(
)
DISTRIBUTED BY HASH(`k0`) BUCKETS 1
properties("replication_num" = "1");

insert into auto_null_list values (null);

select * from auto_null_list;
+-----+
| k0    |
+-----+
| NULL  |
+-----+

select * from auto_null_list partition(px);
+-----+
| k0    |
+-----+
```

```
| NULL |  
+-----+
```

- For Auto Range Partition, **null columns are not supported to be partition columns.**

```
CREATE TABLE `range_table_nullable` (  
  `k1` INT,  
  `k2` DATETIMEV2(3),  
  `k3` DATETIMEV2(6)  
) ENGINE=OLAP  
DUPLICATE KEY(`k1`)  
AUTO PARTITION BY RANGE (date_trunc(`k2`, 'day'))  
(  
)  
DISTRIBUTED BY HASH(`k1`) BUCKETS 16  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 1"  
);  
  
ERROR 1105 (HY000): errCode = 2, detailMessage = AUTO RANGE PARTITION doesn't support NULL column
```

Example

When using Auto Partition, the example in the Application scenarios section can be rewritten as:

```
CREATE TABLE `DAILY_TRADE_VALUE`  
(  
  `TRADE_DATE`          datev2 NOT NULL COMMENT '交易日期',  
  `TRADE_ID`            varchar(40) NOT NULL COMMENT '交易编号',  
  .....  
)  
UNIQUE KEY(`TRADE_DATE`, `TRADE_ID`)  
AUTO PARTITION BY RANGE (date_trunc(`TRADE_DATE`, 'year'))  
(  
)  
DISTRIBUTED BY HASH(`TRADE_DATE`) BUCKETS 10  
PROPERTIES (  
  "replication_num" = "1"  
);
```

Take the example of a table with only two columns, at which point the new table has no default partitions:

```
show partitions from `DAILY_TRADE_VALUE`;  
Empty set (0.12 sec)
```

After inserting data and checking again, it is found that the table has created the corresponding partitions:

```
insert into `DAILY_TRADE_VALUE` values ('2012-12-13', 1), ('2008-02-03', 2), ('2014-11-11', 3);  
  
show partitions from `DAILY_TRADE_VALUE`;  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+  
| PartitionId | PartitionName | VisibleVersion | VisibleVersionTime | State | PartitionKey | Range  
| DistributionKey | Buckets | ReplicationNum | StorageMedium | CooldownTime | RemoteStoragePolicy |  
LastConsistencyCheckTime | DataSize | IsInMemory | ReplicaAllocation | IsMutable |  
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

```

+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
| 180060 | p20080101000000 | 2 | 2023-09-18 21:49:29 | NORMAL | TRADE_DATE | [types:
[DATEV2]; keys: [2008-01-01]; ..types: [DATEV2]; keys: [2009-01-01]; ) | TRADE_DATE | 10 | 1

+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+

```

It can be concluded that the partitions created by Auto Partition share the same functionality as partitions created by manual partitioning.

Conjunct with Dynamic Partition

Doris supports both Auto and Dynamic Partition. In this case, both functions are in effect:

1. Auto Partition will automatically create partitions on demand during data import;
2. Dynamic Partition will automatically create, recycle and dump partitions.

There is no conflict between the two syntaxes, just set the corresponding clauses/attributes at the same time. Please note that it is uncertain whether the partition in current period is created by Auto Partition or Dynamic Partition. Different creation methods will lead to different naming formats for the partitions.

This feature has been supported since Doris 2.1.7

Best Practice

In scenarios where you need to set a limit on the partition lifecycle, you can **disable the creation of Dynamic Partition, leaving the creation of partitions to be completed by Auto Partition**, and complete the management of the partition lifecycle through the Dynamic Partition's function of dynamically reclaiming partitions:

```

create table auto_dynamic(
  k0 datetime(6) NOT NULL
)
auto partition by range (date_trunc(k0, 'year'))
(
)
DISTRIBUTED BY HASH(`k0`) BUCKETS 2
properties(
  "dynamic_partition.enable" = "true",
  "dynamic_partition.prefix" = "p",
  "dynamic_partition.start" = "-50",

```

```

"dynamic_partition.end" = "0", --- Dynamic Partition No Partition Creation
"dynamic_partition.time_unit" = "year",
"replication_num" = "1"
);

```

This way we have both the flexibility of Auto Partition and consistency in partition names.

In some early versions prior to 2.1.7, this feature was not disabled but not recommended.

Partition Management

Since 2.1.6, Doris supports the `partitions` table function and the `auto_partition_name` function, which can be used to easily find and manage partitions for data.

When Auto Partition is enabled, partition names can be mapped to partitions using the `auto_partition_name` function. The `partitions` table function generates detailed partition information from partition names. Let's take the `DAILY_TRADE_VALUE` table as an example to see its current partition after we insert data:

```

select * from partitions("catalog"="internal","database"="optest","table"="DAILY_TRADE_VALUE") where
PartitionName = auto_partition_name('range', 'year', '2008-02-03');

```

PartitionId	PartitionName	VisibleVersion	VisibleVersionTime	State	PartitionKey	Range
127095	p20080101000000	2	2024-11-14 17:29:02	NORMAL	TRADE_DATE	[types: [DATEV2]; keys: [2008-01-01]; ..types: [DATEV2]; keys: [2009-01-01];) TRADE_DATE 10
1	HDD	9999-12-31 23:59:59	\N	985.000 B		
0	tag.location.default: 1	1	1	\N		

In this way the IDs and values of each partition can be precisely filtered for subsequent partition-specific operations (e.g. `insert overwrite partition`).

For a detailed grammar description, see: [auto_partition_name](#), [partitions](#).

Key points

- Similar to regular partitioned tables, auto List Partition supports multi-column partitioning with no syntax differences.

- If partitions are created during data insertion or import processes, and the entire import process is not completed (fails or is canceled), the created partitions will not be automatically deleted.
- Tables using Auto Partition only differ in the method of partition creation, switching from manual to automatic. The original usage of the table and its created partitions remains the same as non-Auto Partition tables or partitions.
- To prevent the accidental creation of too many partitions, Apache Doris controls the maximum number of partitions an Auto Partition table can accommodate through the `max_auto_partition_num` setting in the FE configuration. This value can be adjusted if needed.
- When importing data into a table with Auto Partition enabled, the coordinator sends data with a polling interval different from regular tables. Refer to `olap_table_sink_send_interval_auto_partition_factor` in [BE Configuration](#) for details. This setting does not have an impact after `enable_memtable_on_sink_node` is enabled.
- When use [insert-overwrite](#) to load data into Auto Partition table, the behaviour is detailed in the INSERT OVERWRITE documentation.
- If metadata operations are involved when importing and creating partitions, the import process may fail.

Data Bucketing

A partition can further be divided into different data buckets based on business logic. Each bucket will be stored as a physical data tablet. A reasonable bucket strategy can effectively reduce the amount of data scanned during queries, thereby improving query performance and increasing query concurrency.

Bucket Methods

Doris supports two bucket methods: Hash Bucketing and Random Bucketing.

Hash Bucketing

When creating a table or adding a partition, users need to select one or more columns as the bucket columns and specify the number of buckets. Within the same partition, the system performs a hash calculation based on the bucket key and the number of buckets. Data with the same hash value will be allocated to the same bucket. For example, in the figure below, partition p250102 is divided into three buckets based on the region column, and rows with the same hash value are placed into the same bucket.

hash-bucket

It is recommended to use Hash Bucketing in the following scenarios:

- When the business needs to frequently filter based on a certain field, you can use this field as the bucket key for Hash Bucketing to improve query efficiency.
- When the data distribution in the table is relatively uniform, Hash Bucketing is also a suitable choice.

The following example shows how to create a table with Hash Bucketing. For detailed syntax, please refer to the CREATE TABLE statement.

```
CREATE TABLE demo.hash_bucket_tbl(
  oid      BIGINT,
  dt       DATE,
  region    VARCHAR(10),
  amount    INT
)
DUPLICATE KEY(oid)
PARTITION BY RANGE(dt) (
  PARTITION p250101 VALUES LESS THAN("2025-01-01"),
  PARTITION p250102 VALUES LESS THAN("2025-01-02")
)
DISTRIBUTED BY HASH(region) BUCKETS 8;
```

In the example, `DISTRIBUTED BY HASH(region)` specifies the creation of Hash Bucketing and selects the `region` column as the bucket key. Meanwhile, `BUCKETS 8` specifies the creation of 8 buckets.

Random Bucketing

In each partition, Random Bucketing randomly distributes data to various buckets without relying on the hash value of a certain field. Random Bucketing ensures uniform data distribution, thus avoiding data skew caused by improper bucket key selection.

During data import, each batch of a single import job will be randomly written to a tablet, ensuring uniform data distribution. For example, in one operation, eight batches of data are randomly allocated to three buckets under partition `p250102`.

random-bucket

When using Random Bucketing, you can enable the single-tablet import mode (set `load_to_single_tablet` to `true`). During large-scale data imports, one batch of data will only be written to one data tablet, helping to improve the concurrency and throughput of data imports, reducing write amplification caused by data imports and Compaction, thereby ensuring cluster stability.

It is recommended to use Random Bucketing in the following scenarios:

- In scenarios of arbitrary dimension analysis, where the business does not frequently filter or join queries based on a specific column, you can choose Random Bucketing.
- When the data distribution of frequently queried columns or combinations of columns is extremely uneven, using Random Bucketing can avoid data skew.
- Random Bucketing cannot be pruned based on bucket keys and will scan all data in the hit partition, so it is not recommended for point query scenarios.
- Only DUPLICATE tables can use Random partitioning. UNIQUE and AGGREGATE tables cannot use Random Bucketing.

The following example shows how to create a table with Random Bucketing. For detailed syntax, please refer to the CREATE TABLE statement:

```
CREATE TABLE demo.random_bucket_tbl(
  oid      BIGINT,
  dt       DATE,
  region   VARCHAR(10),
  amount   INT
)
DUPLICATE KEY(oid)
PARTITION BY RANGE(dt) (
  PARTITION p250101 VALUES LESS THAN("2025-01-01"),
  PARTITION p250102 VALUES LESS THAN("2025-01-02")
)
DISTRIBUTED BY RANDOM BUCKETS 8;
```

In the example, the statement `DISTRIBUTED BY RANDOM` specifies the use of Random Bucketing. Creating Random Bucketing does not require selecting a bucket key, and the statement `BUCKETS 8` specifies the creation of 8 buckets.

Choosing Bucket Keys

Note

Only Hash Bucketing requires selecting bucket keys; Random Bucketing does not require selecting bucket keys.

Bucket keys can be one or more columns. If it is a DUPLICATE table, any Key column or Value column can be used as the bucket key. If it is an AGGREGATE or UNIQUE table, to ensure gradual aggregation, the bucket column must be a Key column.

Generally, you can choose bucket keys based on the following rules:

- **Using Query Filter Conditions:** Using query filter conditions for Hash Bucketing helps data pruning and reduces data scan volume;
- **Using High Cardinality Columns:** Selecting high cardinality (many unique values) columns for Hash Bucketing helps to evenly distribute data across each bucket;

- **High-Concurrency Point Query Scenarios:** It is recommended to select a single column or fewer columns for bucketing. Point queries may only trigger a scan of one bucket, and the probability of different queries triggering scans of different buckets is high, thereby reducing the IO impact between queries.
- **High-Throughput Query Scenarios:** It is recommended to select multiple columns for bucketing to make data more evenly distributed. If the query conditions cannot include the equality conditions of all bucket keys, it will increase query throughput and reduce the latency of single queries.

Choosing the Number of Buckets

In Doris, a bucket is stored as a physical file (tablet). The number of tablets in a table equals `partition_num` (number of partitions) multiplied by `bucket_num` (number of buckets). Once the number of Partitions is specified, it cannot be changed.

When determining the number of buckets, you need to consider machine expansion in advance. Starting from version 2.0, Doris supports automatically setting the number of buckets in partitions based on machine resources and cluster information.

Manually Setting the Number of Buckets

You can specify the number of buckets using the `DISTRIBUTED` statement:

```
-- Set hash bucket num to 8
DISTRIBUTED BY HASH(region) BUCKETS 8

-- Set random bucket num to 8
DISTRIBUTED BY RANDOM BUCKETS 8
```

When determining the number of buckets, two principles are usually followed: quantity and size. If there is a conflict between the two, the size principle is prioritized:

- **Size Principle:** Keep each tablet between **1 GB and 20 GB** compressed data (excluding index), or under **10 GB** for Unique Key tables. Too small a tablet may result in poor aggregation effect and increase metadata management pressure; too large a tablet is not conducive to replica migration and supplementation and will increase the cost of retrying Schema Change operations. You can check actual tablet sizes with `SHOW TABLETS FROM your_table`.
- **Quantity Principle:** Without considering expansion, it is recommended that the number of tablets for a table be slightly more than the number of disks in the entire cluster.

The bucket count should be a multiple of the number of BEs for even data distribution. Generally, the bucket count per partition should not exceed **128** — if you need more, consider partitioning the table first.

For example, assuming there are 10 BE machines with one disk per BE, you can follow the recommendations below for data bucketing:

Partition Size	Recommended Number of Buckets
< 1 GB	1 bucket

Partition Size	Recommended Number of Buckets
1-10 GB	10 buckets
10-200 GB	10-20 buckets
> 200 GB	Consider partitioning first

Data sizes refer to compressed data size in Doris. You can check actual sizes with `SHOW TABLETS FROM your_table`.

Note

The data volume of the table can be viewed using the `SHOW DATA` command. The result needs to be divided by the number of replicas and the data volume of the table.

Automatic Bucket Number Setting

The automatic bucket number calculation function will automatically predict the future partition size based on the partition size over a period of time, and determine the number of buckets accordingly.

```
-- Set hash bucket auto
DISTRIBUTED BY HASH(region) BUCKETS AUTO
properties("estimate_partition_size" = "20G")

-- Set random bucket auto
DISTRIBUTED BY HASH(region) BUCKETS AUTO
properties("estimate_partition_size" = "20G")
```

When creating buckets, you can adjust the estimated partition size through the `estimate_partition_size` attribute. This parameter is optional, and if not provided, Doris will default to 10GB. Please note that this parameter is not related to the future partition size calculated by the system based on historical partition data.

Maintaining Data Buckets

Note

Currently, Doris only supports modifying the number of buckets in newly added partitions and does not support the following operations:

1. Modifying the bucketing type
2. Modifying the bucket key
3. Modifying the number of buckets for existing buckets

When creating a table, the number of buckets for each partition is uniformly specified through the `DISTRIBUTED` statement. To cope with data growth or reduction, you can specify the number of buckets for the new partition when dynamically adding partitions. The following example shows how to modify the number of buckets in newly added partitions using the `ALTER TABLE` command:

```
-- Modify hash bucket table
ALTER TABLE demo.hash_bucket_tbl
ADD PARTITION p250103 VALUES LESS THAN("2025-01-03")
DISTRIBUTED BY HASH(region) BUCKETS 16;

-- Modify random bucket table
ALTER TABLE demo.random_bucket_tbl
ADD PARTITION p250103 VALUES LESS THAN("2025-01-03")
DISTRIBUTED BY RANDOM BUCKETS 16;

-- Modify dynamic partition table
ALTER TABLE demo.dynamic_partition_tbl
SET ("dynamic_partition.buckets"="16");
```

After modifying the number of buckets, you can use the SHOW PARTITION command to check the updated number of buckets.

Common Issues

1. Incomplete syntax error prompts may occur in longer table creation statements. Here are some possible syntax errors for manual troubleshooting:

- Syntax structure errors. Please carefully read [HELP CREATE TABLE](#) and check the relevant syntax structure.
- Reserved words. When user-defined names encounter reserved words, they need to be enclosed in backticks ``. It is recommended to use this symbol for all custom names.
- Chinese characters or full-width characters. Non-UTF8 encoded Chinese characters or hidden full-width characters (spaces, punctuation, etc.) can cause syntax errors. It is recommended to use a text editor that displays invisible characters for inspection.

2. Failed to create partition [xxx]. Timeout

Doris creates tables sequentially based on partition granularity. When a partition fails to create, this error may occur. Even if partitions are not used, when there is a problem with table creation, Failed to create partition may still be reported because, as mentioned earlier, Doris creates an unmodifiable default partition for tables without specified partitions.

When encountering this error, it is usually because the BE encountered a problem when creating data tablets. You can troubleshoot by following these steps:

- In the fe.log, search for the Failed to create partition log entry at the corresponding timestamp. In this log entry, you may find a series of number pairs similar to {10001-10010}. The first number in the pair represents the Backend ID, and the second number represents the Tablet ID. For example, this number pair indicates that the creation of Tablet ID 10010 on Backend ID 10001 failed.
- Go to the be.INFO log of the corresponding Backend and search for Tablet ID-related logs within the corresponding time period to find error messages.
- Here are some common tablet creation failure errors, including but not limited to:
 - The BE did not receive the relevant task. In this case, you cannot find Tablet ID-related logs in be.INFO or the BE reports success but actually fails. For these issues, please refer to the [Installation and Deployment](#) section to check the connectivity between FE and BE.
 - Pre-allocated memory failure. This may be because the byte length of a row in the table exceeds 100KB.
 - Too many open files. The number of open file handles exceeds the Linux system limit. You need to modify the handle limit of the Linux system.
- If there is a timeout when creating data tablets, you can also extend the timeout by setting `tablet_create_timeout_second=xxx` and `max_create_table_timeout_second=xxx` in the fe.conf file. By default, `tablet_create_timeout_second` is set to 1 second, and `max_create_table_timeout_second` is set to 60 seconds. The overall timeout is calculated as `min(tablet_create_timeout_second * replication_num, max_create_table_timeout_second)`. For specific parameter settings, please refer to the [FE Configuration](#) section.

3. The table creation command does not return results for a long time.

- Doris's table creation command is a synchronous command. The timeout for this command is currently set simply as (tablet num * replication num) seconds. If many data tablets are created and some of them fail to create, it may result in a long wait before returning an error.
- Under normal circumstances, the table creation statement should return within a few seconds or tens of seconds. If it exceeds one minute, it is recommended to cancel the operation directly and check the relevant errors in the FE or BE logs.

More Help

For more detailed information on data partitioning, you can refer to the [CREATE TABLE](#) command manual or enter `HELP CREATE TABLE;` in the MySQL client to get more help information.

Basic concepts

This document mainly introduces table creation and data partitioning in Doris, as well as potential problems and solutions encountered during table creation operations.

Row & Column

In Doris, data is logically described in the form of tables.

A table consists of rows and columns:

- **Row:** Represents a single line of user data;
- **Column:** Used to describe different fields in a row of data;
- **Columns** can be divided into two types: **Key** and **Value**. From a business perspective, **Key** and **Value** can correspond to **dimension columns** and **metric columns** respectively. The key columns in Apache Doris are those specified in the table creation statement, which are the columns following the keywords `unique key`, `aggregate key`, or `duplicate key`. The remaining columns are value columns. From the perspective of the aggregation model, rows with the same **Key** columns will be aggregated into a single row. The aggregation method for value columns is specified by the user during table creation. For more information on aggregation models, refer to the Doris [Data Model](#).

Partition & Bucket

Doris uses a two-level partitioning and bucketing method to organize and manage data.

Partition

Partition refers to dividing the table into smaller, more manageable, non-overlapping subsets based on specific column values in the table. Each subset of data is called a partition. Each row of data belongs to exactly one specific partition. Partitions can be seen as the smallest logical management unit.

Currently, Doris supports two types of partitioning: **Range** and **List**. If no partition is specified during table creation, Doris will generate a default partition containing all the data in the table, which is transparent to the user.

Partitioning based on data distribution and query patterns offers several benefits:

- **Improved Query Performance:** Partitioning allows the system to prune irrelevant partitions based on the query conditions, reducing the amount of data scanned and significantly improving query efficiency. This is especially beneficial when handling large datasets, as the partition strategy can greatly reduce I/O overhead.
- **Flexible Management:** Partitioning allows data to be split based on logic such as time or geography, facilitating data archiving, cleaning, and backup. For example, partitioning by time can effectively manage historical and newly added data, supporting efficient time-based data maintenance strategies.

Bucket

Bucketing refers to further dividing the data within a partition into smaller, non-overlapping units according to some rule. Each row of data belongs to exactly one specific bucket. Unlike partitioning, which divides data based on specific column values, bucketing attempts to evenly distribute the data across predefined buckets, thereby reducing data skew. Bucketing improves query performance by ensuring even data distribution and enhancing data locality.

Currently, Doris supports two types of bucketing: Hash and Random.

A bucket corresponds to a data shard (Tablet) at the physical level, and data shards are physically stored independently. They are the smallest physical storage units for operations like data movement and replication.

Proper bucketing offers several advantages:

- **Even Data Distribution:** Bucketing evenly distributes data across buckets, reducing the risk of data concentration or skew, and preventing resource overload on specific nodes or storage devices.
- **Reduced Hotspots:** By distributing data evenly, bucketing helps to reduce the risk of overloading specific nodes or partitions, preventing hotspots, and improving system stability and processing capability.
- **Improved Concurrency Performance:** Bucketing enhances the performance of concurrent queries, especially when multiple query requests need to access different data within the same partition. The granularity of bucketing allows the system to efficiently process multiple requests in parallel, thereby improving throughput.

Example of creating a table

CREATE TABLE in Apache Doris is a synchronous command which returns the result once the SQL is executed. Successful returns indicate successful table creation. For more information, refer to [CREATE-TABLE](#) or input the HELP CREATE TABLE command.

The following code sample introduces how to create tables in Apache Doris by RANGE partitioning and Hash buckets.

```
-- Range Partition
CREATE TABLE IF NOT EXISTS example_range_tbl
(
  `user_id` LARGEINT NOT NULL COMMENT "User ID",
  `date` DATE NOT NULL COMMENT "Date when the data are imported",
  `timestamp` DATETIME NOT NULL COMMENT "Timestamp when the data are imported",
  `city` VARCHAR(20) COMMENT "User location city",
  `age` SMALLINT COMMENT "User age",
  `sex` TINYINT COMMENT "User gender",
  `last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT "User last visit time",
  `cost` BIGINT SUM DEFAULT "0" COMMENT "Total user consumption",
  `max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum user dwell time",
  `min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum user dwell time"
)
ENGINE=OLAP
AGGREGATE KEY(`user_id`, `date`, `timestamp`, `city`, `age`, `sex`)
PARTITION BY RANGE(`date`)
(
  PARTITION `p201701` VALUES [("2017-01-01"), ("2017-02-01")),
```

```

PARTITION `p201702` VALUES [("2017-02-01"), ("2017-03-01")),
PARTITION `p201703` VALUES [("2017-03-01"), ("2017-04-01"))
)
DISTRIBUTED BY HASH(`user_id`) BUCKETS 16
PROPERTIES
(
  "replication_num" = "1"
);

```

Here use Aggregate Key Model as an example. In Aggregate Key Model, all columns that are specified with an aggregation type (SUM, REPLACE, MAX, or MIN) are Value columns. The rest are the Key columns.

For more information about what fields can be set in the PROPERTIES section of CREATE TABLE, refer to [CREATE-TABLE](#).

The default type of ENGINE is OLAP. Only OLAP is responsible for data management and storage by Apache Doris itself. Other engine types, such as MySQL, Broker and ES, are essentially just mappings to tables in other external databases or systems, allowing Apache Doris to read this data. However, Apache Doris itself does not create, manage, or store any tables or data for engine types except OLAP.

IF NOT EXISTS indicates that if the table has not been created before, it will be created. Note that this only checks if the table name exists and does not check if the schema of the new table is the same as the schema of an existing table. Therefore, if there is a table with the same name but a different schema, this command will also return successfully, but it does not mean that a new table with a new schema has been created.

Advanced Features and Examples

Doris supports advanced data partitioning methods, including Dynamic Partition, Auto Partition, and Auto Bucket, which enable more flexible data management. The following are examples of implementations: more convenient. Rewrite the above example with Auto Range Partition as follows:

Auto Partition

[Auto Partition](#) supports automatic creation of corresponding partitions according to user-defined rules during data import.

```

CREATE TABLE IF NOT EXISTS example_range_tbl
(
  `user_id` LARGEINT NOT NULL COMMENT "User ID",
  `date` DATE NOT NULL COMMENT "Date when the data are imported",
  `timestamp` DATETIME NOT NULL COMMENT "Timestamp when the data are imported",
  `city` VARCHAR(20) COMMENT "User location city",
  `age` SMALLINT COMMENT "User age",
  `sex` TINYINT COMMENT "User gender",
  `last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT "User last visit time",
  `cost` BIGINT SUM DEFAULT "0" COMMENT "Total user consumption",
  `max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum user dwell time",
  `min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum user dwell time"
)
ENGINE=OLAP
AGGREGATE KEY(`user_id`, `date`, `timestamp`, `city`, `age`, `sex`)
AUTO PARTITION BY RANGE(date_trunc(`date`, 'month')) --- Using months as partition granularity
()
DISTRIBUTED BY HASH(`user_id`) BUCKETS 16
PROPERTIES

```

```
(
  "replication_num" = "1"
);
```

As above, when the data is imported, Doris will automatically create the corresponding partitions as date with a granularity of month level. 2018-12-01 and 2018-12-31 will fall into the same partition, while 2018-11-12 will fall into the leading partition. Auto Partition also supports List partition, please check Auto Partition's documentation for more usage.

Dynamic Partition

[Dynamic Partition](#) is an automatic partition creation and recovery management method based on the real time, rewrite the above example with dynamic partitioning as follows:

```
CREATE TABLE IF NOT EXISTS example_range_tbl
(
  `user_id` LARGEINT NOT NULL COMMENT "User ID",
  `date` DATE NOT NULL COMMENT "Date when the data are imported",
  `timestamp` DATETIME NOT NULL COMMENT "Timestamp when the data are imported",
  `city` VARCHAR(20) COMMENT "User location city",
  `age` SMALLINT COMMENT "User age",
  `sex` TINYINT COMMENT "User gender",
  `last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT "User last visit time",
  `cost` BIGINT SUM DEFAULT "0" COMMENT "Total user consumption",
  `max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum user dwell time",
  `min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum user dwell time"
)
ENGINE=OLAP
AGGREGATE KEY(`user_id`, `date`, `timestamp`, `city`, `age`, `sex`)
PARTITION BY RANGE(`date`)
()
DISTRIBUTED BY HASH(`user_id`) BUCKETS 16
PROPERTIES
(
  "replication_num" = "1",
  "dynamic_partition.enable" = "true",
  "dynamic_partition.time_unit" = "WEEK", --- Partition granularity is week
  "dynamic_partition.start" = "-2", --- Retain two weeks forward
  "dynamic_partition.end" = "2", --- Two weeks after creation in advance
  "dynamic_partition.prefix" = "p",
  "dynamic_partition.buckets" = "8"
);
```

Dynamic partition supports tiered storage, customised copy number and other features, see the dynamic partition documentation for details.

Auto&Dynamic Partition

Supported since Doris 2.1.7

Auto Partition and Dynamic Partition each have their own advantages, and combining the two enables flexible on-demand partition creation and automatic reclamation:

```

CREATE TABLE IF NOT EXISTS example_range_tbl
(
    `user_id` LARGEINT NOT NULL COMMENT "User ID",
    `date` DATE NOT NULL COMMENT "Date when the data are imported",
    `timestamp` DATETIME NOT NULL COMMENT "Timestamp when the data are imported",
    `city` VARCHAR(20) COMMENT "User location city",
    `age` SMALLINT COMMENT "User age",
    `sex` TINYINT COMMENT "User gender",
    `last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT "User last visit time",
    `cost` BIGINT SUM DEFAULT "0" COMMENT "Total user consumption",
    `max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum user dwell time",
    `min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum user dwell time"
)
ENGINE=OLAP
AGGREGATE KEY(`user_id`, `date`, `timestamp`, `city`, `age`, `sex`)
AUTO PARTITION BY RANGE(date_trunc(`date`, 'month')) --- Using months as partition granularity
()
DISTRIBUTED BY HASH(`user_id`) BUCKETS 16
PROPERTIES
(
    "replication_num" = "1",
    "dynamic_partition.enable" = "true",
    "dynamic_partition.time_unit" = "month", --- Both must have the same granularity
    "dynamic_partition.start" = "-2", --- Dynamic Partition automatically cleans up partitions that are more
    than two weeks old
    "dynamic_partition.end" = "0", --- Dynamic Partition does not create future partitions. it is left
    entirely to Auto Partition.
    "dynamic_partition.prefix" = "p",
    "dynamic_partition.buckets" = "8"
);

```

For detailed suggestions on this feature, see [Auto Partition Conjoint with Dynamic Partition](#).

Auto Bucket

When the user is not sure of a reasonable number of buckets, Auto Bucket for Doris to complete the estimation, and the user only needs to provide the estimated amount of table data:

```

CREATE TABLE IF NOT EXISTS example_range_tbl
(
    `user_id` LARGEINT NOT NULL COMMENT "User ID",
    `date` DATE NOT NULL COMMENT "Date when the data are imported",
    `timestamp` DATETIME NOT NULL COMMENT "Timestamp when the data are imported",
    `city` VARCHAR(20) COMMENT "User location city",
    `age` SMALLINT COMMENT "User age",
    `sex` TINYINT COMMENT "User gender",
    `last_visit_date` DATETIME REPLACE DEFAULT "1970-01-01 00:00:00" COMMENT "User last visit time",
    `cost` BIGINT SUM DEFAULT "0" COMMENT "Total user consumption",
    `max_dwell_time` INT MAX DEFAULT "0" COMMENT "Maximum user dwell time",
    `min_dwell_time` INT MIN DEFAULT "99999" COMMENT "Minimum user dwell time"
)
ENGINE=OLAP
AGGREGATE KEY(`user_id`, `date`, `timestamp`, `city`, `age`, `sex`)
PARTITION BY RANGE(`date`)
(
    PARTITION `p201701` VALUES LESS THAN ("2017-02-01"),
    PARTITION `p201702` VALUES LESS THAN ("2017-03-01"),
    PARTITION `p201703` VALUES LESS THAN ("2017-04-01"),
    PARTITION `p2018` VALUES [("2018-01-01"), ("2019-01-01"))
)
DISTRIBUTED BY HASH(`user_id`) BUCKETS AUTO

```

```

|         | "is_being_synced" = "false",
|
|         | "storage_format" = "V2",
|
|         | "light_schema_change" = "true",
|
|         | "disable_auto_compaction" = "false",
|
|         | "enable_single_replica_compaction" = "false"
|
|         | );
|
+-----+
-----+

```

Or run the `show partitions from your_table` command.

```

> show partitions from example_range_tbl

```

Alter partitions

You can add a new partition by running the `alter table add partition` command.

```

ALTER TABLE example_range_tbl ADD PARTITION p201704 VALUES LESS THAN("2020-05-01") DISTRIBUTED BY
HASH(`user_id`) BUCKETS 5;

```

For more information about how to alter partitions, refer to [ALTER-TABLE-PARTITION](#).

Partition Retrieval

The `partitions` table function(supported since 2.1.5) and the `information_schema.partitions` system table(supported since 2.1.7) record partition information for the cluster. The partition information can be extracted from the corresponding table for use when automatically managing partitions:

```

--- Find the partition with the corresponding value in the Auto Partition table.
mysql> select * from partitions("catalog"="internal", "database"="optest", "table"="DAILY_TRADE_VALUE") where
PartitionName = auto_partition_name('range', 'year', '2008-02-03');

Data Types

Apache Doris support standard SQL syntax, using MySQL Network Connection Protocol, highly compatible with MySQL syntax protocol. Therefore, in terms of data type support, Apache Doris aligns as closely as possible with MySQL-related data types

The list of data types supported by Doris is as follows:

Numeric data type

Type Name	Storage (bytes)	Description
BOOLEAN	1	Boolean data type that stores only two values: 0 represents false, 1 represents true.
TINYINT	1	Integer value, signed range is from -128 to 127.
SMALLINT	2	Integer value, signed range is from -32768 to 32767.
INT	4	Integer value, signed range is from -2147483648 to 2147483647.
BIGINT	8	Integer value, signed range is from -9223372036854775808 to 9223372036854775807.
LARGEINT	16	Integer value, range is $[-2^{127} + 1 \text{ to } 2^{127} - 1]$.
FLOAT	4	Single precision floating point number, range is $[-3.4 * 10^{38} \text{ to } 3.4 * 10^{38}]$.
DOUBLE	8	Double precision floating point number, range is $[-1.79 * 10^{308} \text{ to } 1.79 * 10^{308}]$.
DECIMAL	4/8/16/32	An exact fixed-point number defined by precision (total number of digits) and scale (number of digits to the right of the decimal point). Format: DECIMAL(P[,S]), where P is precision and S is scale. The range for P is [1, MAX_P], where MAX_P=38 when enable_decimal256=false, and MAX_P=76 when enable_decimal256=true, and for S is [0, P]. The default value of enable_decimal256 is false. Setting it to true can get more accurate results, but it will bring some performance loss. Storage requirements:

Datetime data type

Type name	Storeage (bytes)	Description
DATE	4	DATE holds values for a calendar year, month and day, the supported range is ['0000-01-01', '9999-12-31']. Default print format: 'yyyy-MM-dd'.

Type name	Storage (bytes)	Description
DATETIME	8	A DATE and TIME combination Format: DATETIME ([P]). The optional parameter P represents time precision, with a value range of [0,6], supporting up to 6 decimal places (microseconds). When not set, it is 0. The supported range is ['0000-01-01 00:00:00 [.000000]', '9999-12-31 23:59:59 [.999999]']. Default print format: 'yyy-MM-dd HH: mm: ss. SSSSSS'.

String data type

Type name	Storage (bytes)	Description
CHAR	M	A FIXED length string, the parameter M specifies the column length in characters. The range of M is from 1 to 255.
VARCHAR	Variable Length	A VARIABLE length string , the parameter M specifies the maximum string length in characters. The range of M is from 1 to 65533. The variable-length string is stored in UTF-8 encoding. English characters occupy 1 byte, and Chinese characters occupy 3 bytes.
STRING	Variable Length	A VARIABLE length string, default supports 1048576 bytes (1 MB), and a limit of maximum precision of 2147483643 bytes (2 GB). Size can be configured string_type_length_soft_limit_bytes adjusted through BE. String type can only be used in value column, not in key column and partition bucket column.

Semi-structured data type

Type name	Storage (bytes)	Description
ARRAY	Variable Length	Arrays composed of elements of type T cannot be used as key columns. Currently supported for use in tables with Duplicate and Unique models.
MAP	Variable Length	Maps consisting of elements of type K and V, cannot be used as Key columns. These maps are currently supported in tables using the Duplicate and Unique models.
STRUCT	Variable Length	A structure composed of multiple Fields can also be understood as a collection of multiple columns. It cannot be used as a Key. Currently, STRUCT can only be used in tables of Duplicate models. The name and number of Fields in a Struct are fixed and are always Nullable.
JSON	Variable Length	Binary JSON type, stored in binary JSON format, access internal JSON fields through JSON function. Supported up to 1048576 bytes (1MB) by default, and can be adjusted to a maximum of 2147483643 bytes (2GB). This limit can be modified through the BE configuration parameter 'jsonb_type_length_soft_limit_bytes'.
VARIANT	Variable Length	The VARIANT data type is dynamically adaptable, specifically designed for semi-structured data like JSON. It can store any JSON object and automatically splits JSON fields into subcolumns for improved storage efficiency and query performance. The length limits and configuration methods are the same as for the STRING type. However, the VARIANT type can only be used in value columns and cannot be used in key columns or partition / bucket columns.

Aggregation data type

Type name	Storage (bytes)	Description
HLL	Variable Length	HLL stands for HyperLogLog, is a fuzzy deduplication. It performs better than Count Distinct when dealing with large datasets. The error rate of HLL is typically around 1%, and sometimes it can reach 2%. HLL cannot be used as a key column, and the aggregation type is HLL_UNION when creating a table. Users do not need to specify the length or default value as it is internally controlled based on the aggregation level of the data. HLL columns can only be queried or used through the companion functions such as hll_union_agg, hll_raw_agg, hll_cardinality, and hll_hash.
BITMAP	Variable Length	BITMAP type can be used in Aggregate tables, Unique tables or Duplicate tables. - When used in a Unique table or a Duplicate table, BITMAP must be employed as non-key columns. - When used in an Aggregate table, BITMAP must also serve as non-key columns, and the aggregation type must be set to BITMAP_UNION during table creation. Users do not need to specify the length or default value as it is internally controlled based on the aggregation level of the data. BITMAP columns can only be queried or used through the companion functions such as bitmap_union_count, bitmap_union, bitmap_hash, and bitmap_hash64.
QUANTILE_STATE	Variable Length	A type used to calculate approximate quantile values. When loading, it performs pre-aggregation for the same keys with different values. When the number of values does not exceed 2048, it records all data in detail. When the number of values is greater than 2048, it employs the TDigest algorithm to aggregate (cluster) the data and store the centroid points after clustering. QUANTILE_STATE cannot be used as a key column and should be paired with the aggregation type QUANTILE_UNION when creating a table. Users do not need to specify the length or default value as it is internally controlled based on the aggregation level of the data. QUANTILE_STATE columns can only be queried or used through the companion functions such as QUANTILE_PERCENT, QUANTILE_UNION, and TO_QUANTILE_STATE.
AGG_STATE	Variable Length	Aggregate function can only be used with state/merge/union function combinators. AGG_STATE cannot be used as a key column. When creating a table, the signature of the aggregate function needs to be declared alongside. Users do not need to specify the length or default value. The actual data storage size depends on the function's implementation.

IP types

Type Name	Storage (bytes)	Description
IPv4	4	It is used in conjunction with the ipv4_* family of functions.
IPv6	16	It is used in conjunction with the ipv6_* family of functions.

You can also view all the data types supported by Doris with the `SHOW DATA TYPES;` statement.

Column Compression

Doris adopts a **columnar storage** model to organize and store data, which is particularly suitable for analytical workloads and can significantly improve query efficiency. In columnar storage, each column of the table is stored independently, facilitating the application of compression techniques and thus improving storage efficiency. Doris provides various compression algorithms, allowing users to choose the appropriate compression method based on workload requirements to optimize storage and query performance.

Why Compression is Needed

In Doris, data compression mainly has the following two core objectives:

- 1. Improve Storage Efficiency** Compression can significantly reduce the disk space required for data storage, allowing more data to be stored on the same physical resources.
- 2. Optimize Performance** The volume of compressed data is smaller, requiring fewer I/O operations during queries, thereby accelerating query response times. Modern compression algorithms typically have very fast decompression speeds, which can enhance read efficiency while reducing storage space.

Supported Compression Algorithms

Doris supports various compression algorithms, each with different trade-offs between compression ratio and decompression speed, allowing users to choose the appropriate algorithm based on their needs:

Compression Type	Characteristics	Applicable Scenarios
No Compression	- No compression applied to data.	Suitable for scenarios where compression is not needed, such as when the data is already compressed or storage space is not an issue.
LZ4	- Very fast compression and decompression speeds. - Moderate compression ratio.	Suitable for scenarios with high decompression speed requirements, such as real-time queries or high-concurrency loads.
LZ4F (LZ4 Frame)	- Extended version of LZ4 supporting more flexible compression configurations. - Fast speed with moderate compression ratio.	Needed when fast compression is required with fine control over configurations.
LZ4HC (LZ4 High Compression)	- Higher compression ratio compared to LZ4, but slower compression speed. - Decompression speed is comparable to LZ4.	Needed when a higher compression ratio is required, while still focusing on decompression speed.
ZSTD (Zstandard)	- High compression ratio with flexible compression level adjustments. - Decompression speed remains fast even at high compression ratios.	Required for high storage efficiency demands, while balancing query performance.
Snappy	- Designed for fast decompression. - Moderate compression ratio.	Required for scenarios with high decompression speed and low CPU overhead demands.

Compression Type	Characteristics	Applicable Scenarios
Zlib	<ul style="list-style-type: none"> - Good balance between compression ratio and speed. - Slower compression and decompression speeds compared to other algorithms, but higher compression ratio. 	Required for scenarios with high storage efficiency demands and insensitivity to decompression speed, such as archiving and cold data storage.

Compression Principles

Column Compression Due to the adoption of columnar storage, Doris can independently compress each column in the table. This method enhances compression efficiency because the data in the same column often has similar distribution characteristics.

Encoding Before Compression Before compressing data, Doris encodes the column data (e.g., **dictionary encoding**, **run-length encoding**, etc.) to transform the data into a form more suitable for compression, further enhancing compression efficiency.

Page Compression Doris adopts a **page**-level compression strategy. The data in each column is divided into multiple pages, and the data within each page is compressed independently. By compressing by page, Doris can efficiently handle large-scale datasets while ensuring high compression ratios and decompression performance.

Configurable Compression Strategies Users can specify the compression algorithm to be used when creating a table. This flexibility allows users to make the best choice between compression efficiency and performance based on specific workloads.

Factors Affecting Compression Effectiveness

Although different compression algorithms have their own advantages and disadvantages, the effectiveness of compression depends not only on the chosen algorithm but also on the following factors:

Order of Data

The order of data has a significant impact on compression effectiveness. For columns with high sequentiality (e.g., timestamps or continuous numeric columns), compression algorithms can typically achieve better results. The more regular the order of the data, the more repetitive patterns the compression algorithm can identify during compression, thus improving the compression ratio.

Data Redundancy

The more duplicate values in a data column, the more pronounced the compression effect. For example, using dictionary encoding on duplicate values can significantly reduce storage space. However, for data columns without obvious duplicates, the compression effect may not meet expectations.

Data Type

The type of data can also affect compression effectiveness. Generally, numeric data types (such as integers and floating-point numbers) are easier to compress than string data types. For data types with a wide range of

values, the effectiveness of the compression algorithm may be impacted.

Column Length

The length of data in a column can also affect compression effectiveness. Shorter columns are usually easier to compress than longer columns because compression algorithms can more efficiently find repetitive patterns in shorter data blocks.

Nulls

When the proportion of null values in a column is high, the compression algorithm may be more effective because it can encode these null values as a special pattern, reducing storage space.

How to Choose the Right Compression Algorithm

Choosing the right compression algorithm should be based on workload characteristics:

- For **high-performance real-time analysis** scenarios, it is recommended to use **LZ4** or **Snappy**.
- For scenarios prioritizing **storage efficiency**, it is recommended to use **ZSTD** or **Zlib**.
- For scenarios that need to balance speed and compression ratio, **LZ4F** can be chosen.
- For **archiving or cold data storage** scenarios, it is advisable to use **Zlib** or **LZ4HC**.

Setting Compression in Doris

When creating a table, you can specify the compression algorithm to determine how the data is stored:

```
```sql CREATE TABLE example_table ( id INT, name STRING, age INT ) DUPLICATE KEY(id) DISTRIBUTED BY HASH(id) BUCKETS 10 PROPERTIES ( "compression" = "zstd" );
```

# Index Overview

---

Database indexes are used to accelerate queries. To speed up different query scenarios, Doris supports various rich indexes.

## Index Types and Principles

From the perspective of accelerating queries and their principles, Doris indexes are categorized into two main types: point query indexes and skip indexes. - **Point Query Indexes:** Commonly used to speed up point queries, the principle is to locate which rows satisfy the WHERE conditions through the index and directly read those rows. Point query indexes are very effective when the number of rows meeting the conditions is small. Doris's point query indexes include Prefix Index and Inverted Index.

- **Prefix Index:** Doris stores data in an ordered manner according to the sort key and creates a sparse prefix index every 1024 rows. The key in the index is the value of the sorted column in the first row of the current 1024 rows. If the query involves a sorted column, the system will find the first row of the relevant 1024-row group and start scanning from there.
- **Inverted Index:** For columns with an inverted index, an posting list is created mapping each value to a set of row ids. For equality queries, it first finds the set of row ids from the posting list, then directly reads the data of those rows, avoiding row-by-row scanning. Inverted indexes can also accelerate range filtering and fulltext search. The algorithms are more complex, but the basic principles are similar. (Note: the previous BITMAP index has been replaced by the more powerful inverted index.)
- **Skip Indexes:** Commonly used to accelerate analysis, the principle is to determine data blocks that do not satisfy the WHERE conditions through the index and skip these blocks, only reading the data blocks that may satisfy the conditions and then performing a row-by-row filter to finally get the rows that meet the conditions. Skip indexes are more effective when the number of rows meeting the conditions is large. Doris's skip indexes include ZoneMap indexes, BloomFilter indexes, and NGram BloomFilter indexes.
  - **ZoneMap Index:** Automatically maintains statistics for each column, recording the maximum, minimum, and whether there are NULL values for each data file (Segment) and data block (Page). For equality queries, range queries, and IS NULL, it can determine whether the data file and data block can contain the data that meets the conditions based on the maximum value, minimum value, and whether there are NULL values. If not, Doris skips reading the corresponding file or data block, reducing IO and accelerating queries.
  - **BloomFilter Index:** Stores values of the indexed column in a BloomFilter data structure, which can quickly determine whether a value is in the BloomFilter with very low storage space. For equality queries, if the value is not in the BloomFilter, the corresponding data file or data block can be skipped, reducing IO and accelerating queries.
  - **NGram BloomFilter Index:** Used to accelerate text LIKE queries. The principle is similar to the BloomFilter index, but instead of storing the original text values, it performs NGram tokenization of the text and stores each token in the BloomFilter. For LIKE queries, the LIKE pattern is also tokenized using NGram. If any token is not in the BloomFilter, the corresponding data file or data block does not meet the LIKE condition and can be skipped.

Among the above indexes, the prefix index and ZoneMap index are built-in indexes automatically maintained by Doris, requiring no user management. Inverted indexes, BloomFilter indexes, and NGram BloomFilter indexes need to be manually created and managed by the user based on the scenario.

- Comparison of characteristics of different types of indexes

Type	Index	Advantages	Limitations
Point Query	Prefix Index	Built-in index, best performance. Only one prefix index per table.	Only one prefix index per table.
Point Query	Inverted Index	Supports tokenization and keyword matching. Building index on any column. Multi-condition combination and accelerating more functions.	Large index storage space, similar to raw data.
Skipp	ZoneMap Index	Built-in index, small index storage space. Only one prefix index per table.	Only one prefix index per table.
Skipp	BloomFilter Index	More precise than ZoneMap, medium index space.	Supports few query types. Only supports equal (not others: not equal, range, LIKE, MATCH).
Skipp	NGram BloomFilter	Supports LIKE acceleration, medium index space.	Supports few query types. Only supports LIKE acceleration.

- List of operators and functions for index acceleration

Operator or Function	Prefix Index	Inverted Index	ZoneMap Index	BloomFilter Index	NGram BloomFilter Index
=	YES	YES	YES	YES	NO
!=	YES	YES	NO	NO	NO
IN	YES	YES	YES	YES	NO
NOT IN	YES	YES	NO	NO	NO
>, >=, <, <=, BETWEEN	YES	YES	YES	NO	NO
IS NULL	YES	YES	YES	NO	NO
IS NOT NULL	YES	YES	NO	NO	NO
LIKE	NO	NO	NO	NO	YES
MATCH, MATCH_*	NO	YES	NO	NO	NO
array_contains	NO	YES	NO	NO	NO
array_overlaps	NO	YES	NO	NO	NO
is_ip_address_in_range	NO	YES	NO	NO	NO

## Index Design Guidelines

The design and optimization of database table indexes are closely related to data distribution and queries, requiring testing and optimization based on the actual scenario. Although there is no “silver bullet,” Doris continuously strives to reduce the difficulty of using indexes. Users can follow these simple guidelines for index selection and testing.

1. Specify the most frequently used filter condition as the KEY to automatically create a prefix index, as it has the best filtering effect. However, only one prefix index can be created per table, so it should be used for the most frequent filter condition.
2. For non-key fields that require filter acceleration, the first choice is to create an inverted index due to its broad applicability and multi-condition combination. The second choice includes the following two indexes:
  - If there is a need for string LIKE matching, add an NGram BloomFilter index.
  - If index storage space is critical, replace the inverted index with a BloomFilter index.
3. If performance is not as expected, analyze the amount of data filtered by the index and the time consumed through QueryProfile. Refer to the detailed documentation of each index for specifics.

# Sort Key and Prefix Index

---

## Index Principles

Doris stores data in a structure similar to SSTable (Sorted String Table). This structure is an ordered data structure that can be sorted and stored according to one or more specified columns. In such a data structure, looking up conditions on all or part of the sorted columns is highly efficient.

In the Aggregate, Unique, and Duplicate data models, the underlying data storage is sorted according to the columns specified in the CREATE TABLE statement under AGGREGATE KEY, UNIQUE KEY, and DUPLICATE KEY respectively. These keys are referred to as sort keys. With sort keys, Doris can quickly locate the required data without scanning the entire table by specifying conditions on the sorted columns during a query, thereby reducing search complexity and speeding up the query.

Based on the sort keys, Doris introduces a prefix index. The prefix index is a sparse index. The data in the table forms a logical data block (Data Block) according to the corresponding number of rows. Each logical data block stores an index entry in the prefix index table, where the length of the index entry does not exceed 36 bytes. The entry content is the prefix composed of the sorted columns of the first row in the data block. When looking up the prefix index table, it helps determine the starting row number of the logical data block where the row data is located. Because the prefix index is relatively small, it can be fully cached in memory, allowing for quick data block location and significantly improving query efficiency.

**The first 36 bytes of a row in a data block are used as the prefix index for that row. When encountering a VARCHAR type, the prefix index is directly truncated. If the first column is VARCHAR, even if it does not reach 36 bytes, it will be directly truncated, and the subsequent columns will not be included in the prefix index.**

## Use Cases

Prefix indexes can speed up equality queries and range queries.

## Managing Indexes

There is no specific syntax to define a prefix index. When creating a table, the first 36 bytes of the table's Key are automatically taken as the prefix index.

## Recommendations for Prefix Index Selection

**Because the Key definition of a table is unique, a table has only one set of prefix indexes. Therefore, it is important to choose an appropriate prefix index when designing the table structure. The following recommendations can be considered:**

1. Choose the fields most commonly used in WHERE filtering conditions as the Key.

2. Place the more frequently used fields at the front, as prefix indexes are only effective for fields in the WHERE condition that are part of the Key's prefix.

For queries that use other columns not covered by the prefix index as conditions, the efficiency may not meet the requirements. There are two solutions: 1. Create an inverted index on the columns that require accelerated queries, as a table can have many inverted indexes. 2. For DUPLICATE tables, multi-prefix indexes can be indirectly achieved by creating corresponding strongly consistent materialized views with adjusted column orders. For more details, refer to query acceleration/materialized views.

## Using Indexes

Prefix indexes are used to accelerate equality and range queries in the WHERE clause. They automatically take effect when applicable, and there is no special syntax required.

The acceleration effect of the prefix index can be analyzed using the following metrics in the Query Profile: - RowsKeyRangeFiltered: The number of rows filtered by the prefix index, which can be compared with other Rows values to analyze the filtering effect of the index.

## Example Usage

- Suppose the sorted columns of a table are as follows, then the prefix index would be: user\_id (8 Bytes) + age (4 Bytes) + message (prefix 20 Bytes).

ColumnName	Type
user_id	BIGINT
age	INT
message	VARCHAR(100)
max_dwell_time	DATETIME
min_dwell_time	DATETIME

- Suppose the sorted columns of a table are as follows, then the prefix index would be user\_name (20 Bytes). Even if it does not reach 36 bytes, it is directly truncated due to encountering VARCHAR, and subsequent columns are not included.

ColumnName	Type
user_name	VARCHAR(20)
age	INT
message	VARCHAR(100)
max_dwell_time	DATETIME
min_dwell_time	DATETIME

- When our query condition is the prefix of the prefix index, it can significantly speed up the query. For example, in the first example, executing the following query:

```
SELECT * FROM table WHERE user_id = 1829239 AND age = 20;
```

This query will be much more efficient than the following query:

```
SELECT * FROM table WHERE age = 20;
```

Therefore, choosing the correct column order when creating a table can greatly improve query efficiency.

# Inverted Index

---

## Indexing Principle

[Inverted Index](#) is a commonly used indexing technique in the field of information retrieval. It divides text into individual words and constructs a word -> document IDs index, allowing for quick searches to determine which documents contain a specific word.

Starting from version 2.0.0, Doris supports inverted indexes, which can be used for full-text searches on text types, equality, and range queries on normal numerical and date types, and quickly filtering rows that meet the criteria from massive amounts of data.

In Doris's implementation of the inverted index, each row in the table corresponds to a document, and each column corresponds to a field in the document. Thus, using an inverted index, you can quickly locate rows containing specific keywords, thereby accelerating the WHERE clause.

Unlike other indexes in Doris, the inverted index uses independent files at the storage layer, corresponding one-to-one with data files but physically stored independently. This approach allows for creating and deleting indexes without rewriting data files, significantly reducing processing overhead.

## Usage Scenarios

Inverted indexes have a wide range of applications and can accelerate equality, range, and full-text searches (keyword matching, phrase matching, etc.). A table can have multiple inverted indexes, and the conditions of multiple inverted indexes can be combined arbitrarily during queries.

The functionality of inverted indexes is briefly introduced as follows:

**1. Accelerate full-text searches for string types** - Support for keyword search, including matching multiple keywords simultaneously MATCH\_ALL and matching any one keyword MATCH\_ANY.

- Support for phrase queries MATCH\_PHRASE
- Support for tokenized regular expression queries MATCH\_REGEXP
- Support for English, Chinese, and Unicode tokenizers

**2. Accelerate normal equality and range queries, covering and replacing the functionality of BITMAP index**

- Support for fast filtering of string, numerical, and datetime types for =, !=, >, >=, <, <=
- Support for fast filtering of string, numerical, and datetime array types for array\_contains

**3. Support for comprehensive logical combinations**

- Not only supports acceleration for AND conditions but also for OR and NOT conditions
- Supports arbitrary logical combinations of multiple conditions with AND, OR, NOT

## 4. Flexible and efficient index management

- Support for defining inverted indexes when creating a table
- Support for adding inverted indexes to existing tables, with incremental index construction without rewriting existing data in the table
- Support for deleting inverted indexes from existing tables without rewriting existing data in the table

### There are some limitations to using inverted indexes:

1. Floating-point types FLOAT and DOUBLE, which have precision issues, do not support inverted indexes due to inaccurate precision. The solution is to use the precisely accurate DECIMAL type, which supports inverted indexes.
2. Some complex data types do not yet support inverted indexes, including MAP, STRUCT, JSON, HLL, BITMAP, QUANTILE\_STATE, AGG\_STATE.
3. DUPLICATE and UNIQUE table models with Merge-on-Write enabled support building inverted indexes on any column. However, AGGREGATE and UNIQUE models without Merge-on-Write enabled only support building inverted indexes on Key columns, as non-Key columns cannot have inverted indexes. This is because these two models require reading all data for merging, so indexes cannot be used for pre-filtering.

## Managing Indexes

### Defining Inverted Indexes When Creating a Table

In the table creation statement, after the COLUMN definition, is the index definition:

```
CREATE TABLE table_name
(
 column_name1 TYPE1,
 column_name2 TYPE2,
 column_name3 TYPE3,
 INDEX idx_name1(column_name1) USING INVERTED [PROPERTIES(...)] [COMMENT 'your comment'],
 INDEX idx_name2(column_name2) USING INVERTED [PROPERTIES(...)] [COMMENT 'your comment']
)
table_properties;
```

Syntax explanation:

1. **idx\_column\_name(column\_name) is mandatory**, column\_name **is the name of the column for the index, must be a column defined earlier**, idx\_column\_name **is the index name, must be unique at the table level, recommended naming convention: prefix idx\_ before the column name**
2. **USING INVERTED is mandatory to specify that the index type is an inverted index**
3. **PROPERTIES is optional to specify additional properties of the inverted index, currently supported properties are:**

## **parser: specifies the tokenizer**

- By default, it is unspecified, meaning no tokenization
  - `english`: English tokenization, suitable for columns with English text, uses spaces and punctuation for tokenization, high performance
  - `chinese`: Chinese tokenization, suitable for columns with mainly Chinese text, lower performance than English tokenization
    - `unicode`: Unicode tokenization, suitable for mixed Chinese and English, and mixed multilingual texts. It can tokenize email prefixes and suffixes, IP addresses, and mixed character and number strings, and can tokenize Chinese by characters.

Tokenization results can be verified using the `TOKENIZE` SQL function, see the following sections for details.

## **parser\_mode**

**Specifies the tokenization mode, currently supported modes for `parser = chinese` are:**

- `fine_grained`: fine-grained mode, tends to generate shorter, more words, e.g., ‘`武汉市长江大桥`’ will be tokenized into ‘`武汉`’, ‘`武汉市`’, ‘`市长`’, ‘`长江`’, ‘`长江大桥`’, ‘`大桥`’
  - `coarse_grained`: coarse-grained mode, tends to generate longer, fewer words, e.g., ‘`武汉市长江大桥`’ will be tokenized into ‘`武汉市`’, ‘`长江大桥`’
  - default `coarse_grained`

## **support\_phrase**

**Specifies whether the index supports `MATCH_PHRASE` phrase query acceleration**

- `true`: supported, but the index requires more storage space
  - `false`: not supported, more storage efficient, can use `MATCH_ALL` to query multiple keywords
    - From versions 2.0.14, 2.1.5 and 3.0.1, the default is `true` if `parser` is set. Otherwise default to `false`.

For example, the following example specifies Chinese tokenization, coarse-grained mode, and supports phrase query acceleration.

```
INDEX idx_name(column_name) USING INVERTED PROPERTIES("parser" = "chinese", "parser_mode" = "coarse_grained", "support_phrase" = "true")
```

## **char\_filter**

**Specifies preprocessing the text before tokenization, usually to affect tokenization behavior**

`char_filter_type`: specifies different functional `char_filters` (currently only supports `char_replace`)

`char_replace` replaces each char in the pattern with a char in the replacement

- `char_filter_pattern`: characters to be replaced
  - `char_filter_replacement`: replacement character array, optional, defaults to a space character

For example, the following example replaces dots and underscores with spaces, thus treating them as word separators, affecting tokenization behavior.

```
INDEX idx_name(column_name) USING INVERTED PROPERTIES("parser" = "unicode", "char_filter_type" = "char_replace", "char_filter_pattern" = "._", "char_filter_replacement" = " ")
```

## **ignore\_above**

### **Specifies the length limit for non-tokenized string indexes (parser not specified)**

- Strings longer than the length set by `ignore_above` will not be indexed. For string arrays, `ignore_above` applies to each array element separately, and elements longer than `ignore_above` will not be indexed.
  - Default is 256, unit is bytes

## **lower\_case**

### **Whether to convert tokens to lowercase for case-insensitive matching**

- `true`: convert to lowercase
  - `false`: do not convert to lowercase
    - From version 2.1.2, the default is `true`, automatically converting to lowercase. Earlier versions default to `false`.

## **stopwords**

### **Specifying the stopwords list to use, which will affect the behavior of the tokenizer**

- The default built-in stopwords list includes meaningless words such as 'is,' 'the,' 'a,' etc. When writing or querying, the tokenizer will ignore words that are in the stopwords list.
  - `none`: Use an empty stopwords list

## **4. COMMENT is optional for specifying index comments**

## **Adding Inverted Indexes to Existing Tables**

### **1. ADD INDEX**

Supports both `CREATE INDEX` and `ALTER TABLE ADD INDEX` syntax. The parameters are the same as those used when defining indexes during table creation.

```
-- Syntax 1
CREATE INDEX idx_name ON table_name(column_name) USING INVERTED [PROPERTIES(...)] [COMMENT 'your comment'];
-- Syntax 2
ALTER TABLE table_name ADD INDEX idx_name(column_name) USING INVERTED [PROPERTIES(...)] [COMMENT 'your comment'];
```

## 2. BUILD INDEX

The CREATE / ADD INDEX operation only adds the index definition. New data written after this operation will generate inverted indexes, but existing data requires using BUILD INDEX to trigger indexing:

```
-- Syntax 1, by default, builds the index for all partitions in the table
BUILD INDEX index_name ON table_name;
-- Syntax 2, you can specify partitions, one or more
BUILD INDEX index_name ON table_name PARTITIONS(partition_name1, partition_name2);
```

To check the progress of BUILD INDEX, use SHOW BUILD INDEX:

```
SHOW BUILD INDEX [FROM db_name];
-- Example 1, view the progress of all BUILD INDEX tasks
SHOW BUILD INDEX;
-- Example 2, view the progress of BUILD INDEX tasks for a specific table
SHOW BUILD INDEX where TableName = "table1";
```

To cancel BUILD INDEX, use CANCEL BUILD INDEX:

```
CANCEL BUILD INDEX ON table_name;
CANCEL BUILD INDEX ON table_name (job_id1, job_id2, ...);
```

**BUILD INDEX creates an asynchronous task executed by multiple threads on each BE. The number of threads can be set using the BE config `alter_index_worker_count`, with a default value of 3.**

In versions before and 2.1.4, BUILD INDEX would keep retrying until it succeeded. Starting from this version, failure and timeout mechanisms prevent endless retries.

1. If the majority of replicas for a tablet fail to BUILD INDEX, the entire BUILD INDEX operation fails.
2. If the time exceeds `alter_table_timeout_second`, the BUILD INDEX operation times out.
3. Users can trigger BUILD INDEX multiple times; indexes that have already been built successfully will not be rebuilt.

## Deleting Inverted Indexes from Existing Tables

```
-- Syntax 1
DROP INDEX idx_name ON table_name;
-- Syntax 2
ALTER TABLE table_name DROP INDEX idx_name;
```

**DROP INDEX deletes the index definition, so new data will no longer write to the index. This creates an asynchronous task to perform the index deletion, executed by multiple threads on each BE. The number of threads can be set using the BE parameter `alter_index_worker_count`, with a default value of 3.**

## Viewing Inverted Index

- Syntax 1: The INDEX section in the table schema with USING INVERTED indicates an inverted index SHOW CREATE TABLE table\_name;
- Syntax 2: IndexType as INVERTED indicates an inverted index SHOW INDEX FROM table\_name;

## Using Indexes

### Accelerating Queries with Inverted Indexes

```
-- 1. Full-text search keyword matching using MATCH_ANY and MATCH_ALL
SELECT * FROM table_name WHERE column_name MATCH_ANY | MATCH_ALL 'keyword1 ...';

-- 1.1 Rows in the content column containing keyword1
SELECT * FROM table_name WHERE content MATCH_ANY 'keyword1';

-- 1.2 Rows in the content column containing keyword1 or keyword2; you can add more keywords
SELECT * FROM table_name WHERE content MATCH_ANY 'keyword1 keyword2';

-- 1.3 Rows in the content column containing both keyword1 and keyword2; you can add more keywords
SELECT * FROM table_name WHERE content MATCH_ALL 'keyword1 keyword2';

-- 2. Full-text search phrase matching using MATCH_PHRASE

-- 2.1 Rows in the content column containing both keyword1 and keyword2, where keyword2 must immediately
follow keyword1
-- 'keyword1 keyword2', 'wordx keyword1 keyword2', 'wordx keyword1 keyword2 wordy' all match because they
contain 'keyword1 keyword2' with keyword2 immediately following keyword1
-- 'keyword1 wordx keyword2' does not match because there is a word between keyword1 and keyword2
-- 'keyword2 keyword1' does not match because the order is reversed
-- To use MATCH_PHRASE, you need to enable "support_phrase" = "true" in PROPERTIES.
SELECT * FROM table_name WHERE content MATCH_PHRASE 'keyword1 keyword2';

-- 2.2 Rows in the content column containing both keyword1 and keyword2, with a slop (maximum word distance)
of 3
-- 'keyword1 keyword2', 'keyword1 a keyword2', 'keyword1 a b c keyword2' all match because the slop is 0, 1,
and 3 respectively, all within 3
-- 'keyword1 a b c d keyword2' does not match because the slop is 4, exceeding 3
-- 'keyword2 keyword1', 'keyword2 a keyword1', 'keyword2 a b c keyword1' also match because when slop > 0,
the order of keyword1 and keyword2 is not required. To enforce the order, Doris provides a + sign after slop
SELECT * FROM table_name WHERE content MATCH_PHRASE 'keyword1 keyword2 ~3';
-- To enforce order, use a positive sign with slop; 'keyword1 a b c keyword2' matches, while 'keyword2 a b c
keyword1' does not
SELECT * FROM table_name WHERE content MATCH_PHRASE 'keyword1 keyword2 ~3+';

-- 2.3 Prefix matching the last word keyword2, with a default limit of 50 prefixes (controlled by session
variable inverted_index_max_expansions)
-- It is necessary to ensure that keyword1 and keyword2 remain adjacent in the original text after
tokenization, with no other words in between.
-- 'keyword1 keyword2abc' matches because keyword1 is identical and keyword2abc is a prefix of keyword2
-- 'keyword1 keyword2' also matches because keyword2 is a prefix of keyword2
-- 'keyword1 keyword3' does not match because keyword3 is not a prefix of keyword2
-- 'keyword1 keyword3abc' does not match because keyword3abc is not a prefix of keyword2
SELECT * FROM table_name WHERE content MATCH_PHRASE_PREFIX 'keyword1 keyword2';

-- 2.4 If only one word is provided, it defaults to a prefix query with a limit of 50 prefixes (controlled by
session variable inverted_index_max_expansions)
SELECT * FROM table_name WHERE content MATCH_PHRASE_PREFIX 'keyword1';
```

```
-- 2.5 Regular expression matching on tokenized words, with a default limit of 50 matches (controlled by
session variable inverted_index_max_expansions)
-- Similar to MATCH_PHRASE_PREFIX but with regex instead of prefix
SELECT * FROM table_name WHERE content MATCH_REGEXP 'key.*';

-- 3. Normal equality, range, IN, and NOT IN queries using standard SQL syntax, for example:
SELECT * FROM table_name WHERE id = 123;
SELECT * FROM table_name WHERE ts > '2023-01-01 00:00:00';
SELECT * FROM table_name WHERE op_type IN ('add', 'delete');

-- 4. Full-text search across multiple columns using the multi_match function
-- Parameters:
-- First N parameters are column names to search
-- Second-to-last parameter specifies match mode: 'any'/'all'/'phrase'/'phrase_prefix'
-- Last parameter is the keyword or phrase to search for

-- 4.1 Rows where 'keyword1' appears in ANY of col1,col2,col3 (OR logic)
select * FROM table_name WHERE multi_match(col1, col2, col3, 'any', 'keyword1');

-- 4.2 Rows where 'keyword1' appears in ALL of col1,col2,col3 (AND logic)
select * FROM table_name WHERE multi_match(col1, col2, col3, 'all', 'keyword1');

-- 4.3 Rows where the exact phrase 'keyword1' appears in ANY of col1,col2,col3 (exact phrase match)
select * FROM table_name WHERE multi_match(col1, col2, col3, 'phrase', 'keyword1');

-- 4.4 Rows where a phrase starting with 'keyword1' appears in ANY of col1,col2,col3 (phrase prefix match)
-- For example, will match content like "keyword123"
select * FROM table_name WHERE multi_match(col1, col2, col3, 'phrase_prefix', 'keyword1');
```

## Analyzing Index Acceleration Effects Through Profiles

Inverted query acceleration can be toggled using the session variable `enable_inverted_index_query`, which is set to true by default. To verify the acceleration effect of the index, it can be set to false to turn it off.

The acceleration effect of the inverted index can be analyzed using the following metrics in the Query Profile: -

RowsInvertedIndexFiltered: The number of rows filtered by the inverted index, which can be compared with other Rows values to analyze the filtering effect of the index. - InvertedIndexFilterTime: The time consumed by the inverted index. - InvertedIndexSearcherOpenTime: The time taken to open the inverted index. - InvertedIndexSearcherSearchTime: The time taken for internal queries within the inverted index.

## Verifying Tokenization Effects Using Tokenization Functions

To check the actual effect of tokenization or to tokenize a piece of text, you can use the `TOKENIZE` function for verification.

The first parameter of the `TOKENIZE` function is the text to be tokenized, and the second parameter specifies the tokenization parameters used when creating the index.

```
SELECT TOKENIZE('I love Doris', "parser="english"); +-----+ | tokenize('I love
Doris', "parser="english") | +-----+ | ["I", "love", "doris"] | +
-----+
```

## Usage Example

Demonstrating the creation of an inverted index, full-text search, and regular queries using 1 million

records from HackerNews. This includes a simple performance comparison with queries without indexing.

### ### Table Creation

```
```sql
CREATE DATABASE test_inverted_index;

USE test_inverted_index;

-- Create a table with an inverted index on the comment field
-- USING INVERTED specifies the index type as an inverted index
-- PROPERTIES("parser" = "english") specifies using the "english" tokenizer; other options include
-- "chinese" for Chinese tokenization and "unicode" for mixed-language tokenization. If the "parser" parameter
-- is not specified, no tokenization is applied.

CREATE TABLE hackernews_1m
(
  `id` BIGINT,
  `deleted` TINYINT,
  `type` String,
  `author` String,
  `timestamp` DateTimeV2,
  `comment` String,
  `dead` TINYINT,
  `parent` BIGINT,
  `poll` BIGINT,
  `children` Array<BIGINT>,
  `url` String,
  `score` INT,
  `title` String,
  `parts` Array<INT>,
  `descendants` INT,
  INDEX idx_comment (`comment`) USING INVERTED PROPERTIES("parser" = "english") COMMENT 'inverted index for
comment'
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 10
PROPERTIES ("replication_num" = "1");
```

Data Import

Importing Data via Stream Load

```
wget https://qa-build.oss-cn-beijing.aliyuncs.com/regression/index/hacknernews_1m.csv.gz

curl --location-trusted -u root: -H "compress_type:gzip" -T hacknernews_1m.csv.gz -XPUT
http://127.0.0.1:8030/api/test_inverted_index/hacknernews_1m/_stream_load
{
  "TxnId": 2,
  "Label": "a8a3e802-2329-49e8-912b-04c800a461a6",
  "TwoPhaseCommit": "false",
  "Status": "Success",
  "Message": "OK",
  "NumberTotalRows": 1000000,
  "NumberLoadedRows": 1000000,
  "NumberFilteredRows": 0,
  "NumberUnselectedRows": 0,
  "LoadBytes": 130618406,
  "LoadTimeMs": 8988,
  "BeginTxnTimeMs": 23,
  "StreamLoadPutTimeMs": 113,
  "ReadDataTimeMs": 4788,
```

```

    "WriteDataTimeMs": 8811,
    "CommitAndPublishTimeMs": 38
}

```

Confirm Data Import Success with SQL count()

```

SELECT count() FROM hackernews_1m;
+-----+
| count() |
+-----+
| 1000000 |
+-----+

```

Queries

01 Full-Text Search

- Using LIKE to match and count rows containing 'OLAP' in the comment column took 0.18s.

```

SELECT count() FROM hackernews_1m WHERE comment LIKE '%OLAP%';
+-----+
| count() |
+-----+
|      34 |
+-----+

```

- Using full-text search with MATCH_ANY based on the inverted index to count rows containing 'OLAP' in the comment column took 0.02s, resulting in a 9x speedup. The performance improvement would be even more significant on larger datasets.

The difference in the number of results is due to the inverted index normalizing the terms by converting them to lowercase, among other processes, hence MATCH_ANY yields more results than LIKE.

```

SELECT count() FROM hackernews_1m WHERE comment MATCH_ANY 'OLAP';
+-----+
| count() |
+-----+
|      35 |
+-----+

```

- Similarly, comparing the performance for counting occurrences of 'OLTP', 0.07s vs 0.01s. Due to caching, both LIKE and MATCH_ANY improved, but the inverted index still provided a 7x speedup.

```

SELECT count() FROM hackernews_1m WHERE comment LIKE '%OLTP%';
+-----+
| count() |
+-----+
|      48 |
+-----+

SELECT count() FROM hackernews_1m WHERE comment MATCH_ANY 'OLTP';
+-----+
| count() |
+-----+

```

count()
51

- Counting rows where both 'OLAP' and 'OLTP' appear took 0.13s vs 0.01s, a 13x speedup.

To require multiple terms to appear simultaneously (AND relationship), use MATCH_ALL 'keyword1 keyword2 ...'.

```
SELECT count() FROM hackernews_1m WHERE comment LIKE '%OLAP%' AND comment LIKE '%OLTP%';
```

count()
14

```
SELECT count() FROM hackernews_1m WHERE comment MATCH_ALL 'OLAP OLTP';
```

count()
15

- Counting rows where either 'OLAP' or 'OLTP' appears took 0.12s vs 0.01s, a 12x speedup.

To require any one or more of multiple terms to appear (OR relationship), use MATCH_ANY 'keyword1 keyword2 ...'.

```
SELECT count() FROM hackernews_1m WHERE comment LIKE '%OLAP%' OR comment LIKE '%OLTP%';
```

count()
68

```
SELECT count() FROM hackernews_1m WHERE comment MATCH_ANY 'OLAP OLTP';
```

count()
71

02 Standard Equality and Range Queries

- Range query on a DateTime type column

```
SELECT count() FROM hackernews_1m WHERE timestamp > '2007-08-23 04:17:00';
```

count()
999081

- Adding an inverted index for the timestamp column

```
-- For date-time types, USING INVERTED does not require specifying a parser
-- CREATE INDEX is one syntax for creating an index, another method will be shown later
CREATE INDEX idx_timestamp ON hackernews_1m(timestamp) USING INVERTED;
```

```
BUILD INDEX idx_timestamp ON hackernews_1m;
```

- Checking the index creation progress. From the difference between FinishTime and CreateTime, we can see that building the inverted index for 1 million rows on the timestamp column took only 1 second.

```
SHOW ALTER TABLE COLUMN;
```

JobId	TableName	CreateTime	FinishTime	IndexName	IndexId
10030	hackernews_1m	2023-02-10 19:44:12.929	2023-02-10 19:44:13.938	hackernews_1m	10031
10008		1:1994690496	3	FINISHED	NULL
				2592000	

```
-- If the table has no partitions, PartitionName defaults to TableName
```

```
SHOW BUILD INDEX;
```

JobId	TableName	PartitionName	AlterInvertedIndexes	CreateTime	FinishTime	TransactionId	State	Msg	Progress
10191	hackernews_1m	hackernews_1m	[ADD INDEX idx_timestamp (`timestamp`) USING INVERTED],	2023-06-26 15:32:33.894	2023-06-26 15:32:34.847	3	FINISHED	NULL	

- After the index is created, range queries use the same query syntax. Doris will automatically recognize the index for optimization. However, due to the small dataset, the performance difference is not significant.

```
SELECT count() FROM hackernews_1m WHERE timestamp > '2007-08-23 04:17:00';
```

count()
999081

- Performing similar operations on a numeric column parent with an equality match query.

```
SELECT count() FROM hackernews_1m WHERE parent = 11189;
```

count()
2

```
-- For numeric types, USING INVERTED does not require specifying a parser
```

```
-- ALTER TABLE t ADD INDEX is the second syntax for creating an index
ALTER TABLE hackernews_1m ADD INDEX idx_parent(parent) USING INVERTED;
```

```
-- Execute BUILD INDEX to create the inverted index for existing data
BUILD INDEX idx_parent ON hackernews_1m;
```

```
SHOW ALTER TABLE COLUMN;
```

JobId	TableName	CreateTime	FinishTime	IndexName	IndexId	
OriginIndexId	SchemaVersion	TransactionId	State	Msg	Progress	Timeout
10030	hackernews_1m	2023-02-10 19:44:12.929	2023-02-10 19:44:13.938	hackernews_1m	10031	
10008	1:1994690496	3	FINISHED	NULL	2592000	
10053	hackernews_1m	2023-02-10 19:49:32.893	2023-02-10 19:49:33.982	hackernews_1m	10054	
10008	1:378856428	4	FINISHED	NULL	2592000	

```
SHOW BUILD INDEX;
```

JobId	TableName	PartitionName	AlterInvertedIndexes	CreateTime	FinishTime	TransactionId	State	Msg	Progress
11005	hackernews_1m	hackernews_1m	[ADD INDEX idx_parent (`parent`) USING INVERTED],	2023-06-26 16:25:10.167	2023-06-26 16:25:10.838	1002	FINISHED	NULL	

```
SELECT count() FROM hackernews_1m WHERE parent = 11189;
```

count()
2

- Creating an inverted index for the string column author without tokenization. Equality queries can also leverage the index for speedup.

```
```sql SELECT count() FROM hackernews_1m WHERE author = 'faster';
+-----+ | count() | +-----+
20 | +-----+
```

– Here, USING INVERTED is used without tokenizing the author column, treating it as a single term

```
ALTER TABLE hackernews_1m ADD INDEX idx_author(author) USING INVERTED;
```

– Execute BUILD INDEX to add the inverted index for existing data

```
BUILD INDEX idx_author ON hackernews_1m;
```

Creating an incremental index for 1 million author records took only 1.5 seconds.

```
SHOW ALTER TABLE COLUMN;
```

JobId	TableName		CreateTime		FinishTime	
			IndexName		IndexId	
OriginIndexId	SchemaVersion	TransactionId	State	Msg	Progress	Timeout

10030	hackernews_1m	2023-02-10 19:44:12.929	2023-02-10 19:44:13.938	hackernews_1m	10031	10008
1:1994690496	3	FINISHED	NULL	2592000		
10053	hackernews_1m	2023-02-10 19:49:32.893	2023-02-10 19:49:33.982	hackernews_1m	10054	10008
1:378856428	4	FINISHED	NULL	2592000		
10076	hackernews_1m	2023-02-10 19:54:20.046	2023-02-10 19:54:21.521	hackernews_1m	10077	10008
1:1335127701	5	FINISHED	NULL	2592000		

```
SHOW BUILD INDEX ORDER BY CreateTime DESC LIMIT 1;
```

JobId	TableName	PartitionName	AlterInvertedIndexes	CreateTime
FinishTime	TransactionId	State	Msg	Progress
13006	hackernews_1m	hackernews_1m	[ADD INDEX idx_author (`author`) USING INVERTED],	2023-06-26 17:23:02.610
2023-06-26 17:23:03.755	3004	FINISHED	NULL	

– After creating the index, string equality matches also showed significant acceleration.

```
SELECT count() FROM hackernews_1m WHERE author = 'faster';
```

count()
20

# BloomFilter Index

## Indexing Principles

The BloomFilter index is a type of skip index based on BloomFilter. Its principle is to use BloomFilter to skip data blocks that do not meet the specified conditions for equality queries, thereby reducing IO and accelerating queries.

BloomFilter is a fast lookup algorithm proposed by Bloom in 1970, which uses multiple hash functions. It is commonly used in scenarios where quick determination of whether an element belongs to a set is needed without requiring 100% accuracy. BloomFilter has the following characteristics:

- A space-efficient probabilistic data structure used to check if an element is in a set.
- For a membership check, BloomFilter returns one of two results: possibly in the set or definitely not in the set.

A BloomFilter consists of a very long binary bit array and a series of hash functions. The bit array is initially all set to 0. When an element is to be checked, it is hashed by a series of hash functions to generate a series of values, and the bits at these positions in the array are set to 1.

The figure below shows an example of a BloomFilter with  $m=18$  and  $k=3$  (where  $m$  is the size of the bit array and  $k$  is the number of hash functions). Elements  $x$ ,  $y$ , and  $z$  in the set are hashed by 3 different hash functions into the bit array. When querying element  $w$ , if any bit calculated by the hash functions is 0, then  $w$  is not in the set. Conversely, if all bits are 1, it only indicates that  $w$  may be in the set, but not definitely, due to possible hash collisions.

Bloom\_filter

Thus, if all bits at the calculated positions are 1, it only indicates that the element may be in the set, not definitely, due to possible hash collisions. This is the “false positive” nature of BloomFilter. Therefore, a BloomFilter-based index can only skip data that does not meet the conditions but cannot precisely locate data that does.

The Doris BloomFilter index is built on a per-page basis, with each data block storing a BloomFilter. During writing, each value in the data block is hashed into the corresponding BloomFilter. During querying, for equality

conditions, it is checked if the BloomFilter of each data block contains the value. If not, the data block is skipped, reducing IO and speeding up the query.

## Use Cases

BloomFilter indexes can accelerate equality queries (including = and IN) and are effective for high cardinality fields, such as unique id fields like userid.

### BloomFilter has the following limitations:

1. It has no effect on queries other than in and =, such as !=, NOT IN, >, <, etc.
2. It does not support BloomFilter indexing on columns of type Tinyint, Float, Double.
3. It has limited acceleration effect on low cardinality fields. For example, a “gender” field with only two values will likely be included in almost every data block, making the BloomFilter index meaningless.

To check the effect of a BloomFilter index on a query, you can analyze relevant metrics in the Query Profile.

- BlockConditionsFilteredBloomFilterTime is the time consumed by the BloomFilter index.
- RowsBloomFilterFiltered is the number of rows filtered out by the BloomFilter. You can compare it with other Rows values to analyze the filtering effect of the BloomFilter index.

## Managing Indexes

### Creating a BloomFilter Index When Creating a Table

Due to historical reasons, the syntax for defining BloomFilter indexes differs from the general INDEX syntax used for inverted indexes. BloomFilter indexes are specified in the table’s PROPERTIES using “bloom\_filter\_columns”, which can specify one or more fields.

```
PROPERTIES (
 "bloom_filter_columns" = "column_name1,column_name2"
);
```

### Viewing BloomFilter Indexes

```
SHOW CREATE TABLE table_name;
```

### Adding or Removing BloomFilter Indexes on an Existing Table

Modify the table’s bloom\_filter\_columns property via ALTER TABLE to add or remove BloomFilter indexes.

#### Add a BloomFilter index for column\_name3

```
ALTER TABLE table_name SET ("bloom_filter_columns" = "column_name1,column_name2,column_name3");
```

## Remove the BloomFilter index for column\_name1

```
ALTER TABLE table_name SET ("bloom_filter_columns" = "column_name2,column_name3");
```

## Using Indexes

BloomFilter index is used to accelerate equality queries in the WHERE clause. It automatically takes effect when applicable, and there is no special syntax required.

The acceleration effect of the BloomFilter index can be analyzed using the following metrics in the Query Profile: - RowsBloomFilterFiltered: The number of rows filtered by the BloomFilter index, which can be compared with other Rows values to analyze the filtering effect of the index. - BlockConditionsFilteredBloomFilterTime: The time consumed by the BloomFilter inverted index.

## Usage Example

Here is an example of how to create a BloomFilter index in Doris.

The BloomFilter index in Doris is created by adding the “bloom\_filter\_columns” property in the CREATE TABLE statement, with k1, k2, k3 being the key columns for the BloomFilter index. For example, the following creates BloomFilter indexes on saler\_id and category\_id.

```
CREATE TABLE IF NOT EXISTS sale_detail_bloom (
 sale_date date NOT NULL COMMENT "Sale date",
 customer_id int NOT NULL COMMENT "Customer ID",
 saler_id int NOT NULL COMMENT "Salesperson",
 sku_id int NOT NULL COMMENT "Product ID",
 category_id int NOT NULL COMMENT "Product category",
 sale_count int NOT NULL COMMENT "Sales quantity",
 sale_price DECIMAL(12,2) NOT NULL COMMENT "Unit price",
 sale_amt DECIMAL(20,2) COMMENT "Total sales amount"
)
DUPLICATE KEY(sale_date, customer_id, saler_id, sku_id, category_id)
DISTRIBUTED BY HASH(saler_id) BUCKETS 10
PROPERTIES (
 "replication_num" = "1",
 "bloom_filter_columns"="saler_id,category_id"
);
```

# N-Gram BloomFilter Index

---

## Indexing Principles

n-gram tokenization is a method of splitting a sentence or a piece of text into multiple adjacent word groups. The NGram BloomFilter index, similar to the BloomFilter index, is a skip index based on BloomFilter.

Unlike the BloomFilter index, the NGram BloomFilter index is used to accelerate text LIKE queries. Instead of storing the original text values, it tokenizes the text using NGram and stores each token in the BloomFilter. For LIKE queries, the pattern in LIKE '%pattern%' is also tokenized using NGram. Each token is checked against the BloomFilter, and if any token is not found, the corresponding data block does not meet the LIKE condition and can be skipped, reducing IO and accelerating the query.

## Use Cases

The NGram BloomFilter index can only accelerate string LIKE queries, and the number of consecutive characters in the LIKE pattern must be greater than or equal to the N defined in the NGram index.

**- NGram BloomFilter only supports string columns and can only accelerate LIKE queries.**

- NGram BloomFilter index and BloomFilter index are mutually exclusive, meaning a column can only have one or the other.
- The performance analysis of the NGram BloomFilter index is similar to that of the BloomFilter index.

## Managing Indexes

### Creating an NGram BloomFilter Index

The index definition follows the COLUMN definition in the CREATE TABLE statement:

```
INDEX `idx_column_name` (`column_name`) USING NGRAM_BF PROPERTIES("gram_size"="3", "bf_size"="1024") COMMENT 'username ngram_bf index'
```

Explanation of the syntax:

1. `idx_column_name(column_name)` is mandatory. `column_name` is the column to be indexed and must appear in the column definitions above. `idx_column_name` is the index name, which must be unique at the table level. It is recommended to name it with a prefix `idx_` followed by the column name.
2. `USING NGRAM_BF` is mandatory and specifies that the index type is an NGram BloomFilter index.
3. `PROPERTIES` is optional and is used to specify additional properties for the NGram BloomFilter index. The supported properties are:

- **gram\_size**: The N in NGram, specifying the number of consecutive characters to form a token. For example, 'This is a simple ngram example' with N = 3 would be tokenized into 'This is a', 'is a simple', 'a simple ngram', 'simple ngram example' (4 tokens).
- **bf\_size**: The size of the BloomFilter in bits. bf\_size determines the size of the index corresponding to each data block. The larger this value, the more storage space it occupies, but the lower the probability of hash collisions.

It is recommended to set **gram\_size** to the minimum length of the string in LIKE queries but not less than 2. Generally, "gram\_size"="3", "bf\_size"="1024" is recommended, then adjust based on the Query Profile.

4. COMMENT is optional and specifies an index comment.

## Viewing NGram BloomFilter Index

– Syntax 1: The INDEX section in the table schema with USING NGRAM\_BF indicates an inverted index

```
SHOW CREATE TABLE table_name;
```

– Syntax 2: IndexType as NGRAM\_BF indicates an inverted index

```
SHOW INDEX FROM table_name;
```

## Deleting an NGram BloomFilter Index

```
ALTER TABLE table_ngrambf DROP INDEX idx_ngrambf;
```

## Modifying an NGram BloomFilter Index

```
CREATE INDEX idx_column_name2(column_name2) ON table_ngrambf USING NGRAM_BF PROPERTIES("gram_size"="3",
"bf_size"="1024") COMMENT 'username ngram_bf index';
```

```
ALTER TABLE table_ngrambf ADD INDEX idx_column_name2(column_name2) USING NGRAM_BF PROPERTIES("gram_size"="3",
"bf_size"="1024") COMMENT 'username ngram_bf index';
```

## Using Indexes

To use NGram BloomFilter index, you need to set the following parameters (enable\_function\_pushdown is false by default):

```
SET enable_function_pushdown = true;
```

NGram BloomFilter index is used to accelerate LIKE queries, for example: SELECT count() FROM table1 WHERE message LIKE '%error%';

The acceleration effect of the BloomFilter index (including NGram) can be analyzed using the following metrics in the Query Profile: - RowsBloomFilterFiltered: The number of rows filtered by the BloomFilter index, which

can be compared with other Rows values to analyze the filtering effect of the index. -  
BlockConditionsFilteredBloomFilterTime: The time consumed by the BloomFilter inverted index.

## Usage Example

This section demonstrates the usage and effectiveness of the NGram BloomFilter index using a dataset of Amazon product reviews, amazon\_reviews.

### Table Creation

```
CREATE TABLE `amazon_reviews` (
 `review_date` int(11) NULL,
 `marketplace` varchar(20) NULL,
 `customer_id` bigint(20) NULL,
 `review_id` varchar(40) NULL,
 `product_id` varchar(10) NULL,
 `product_parent` bigint(20) NULL,
 `product_title` varchar(500) NULL,
 `product_category` varchar(50) NULL,
 `star_rating` smallint(6) NULL,
 `helpful_votes` int(11) NULL,
 `total_votes` int(11) NULL,
 `vine` boolean NULL,
 `verified_purchase` boolean NULL,
 `review_headline` varchar(500) NULL,
 `review_body` string NULL
) ENGINE=OLAP
DUPLICATE KEY(`review_date`)
COMMENT 'OLAP'
DISTRIBUTED BY HASH(`review_date`) BUCKETS 16
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1",
 "compression" = "ZSTD"
);
```

### Data Import

Download the dataset using wget or other tools from the following URLs:

```
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2010.snappy.parquet
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2011.snappy.parquet
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2012.snappy.parquet
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2013.snappy.parquet
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2014.snappy.parquet
https://datasets-documentation.s3.eu-west-3.amazonaws.com/amazon_reviews/amazon_reviews_2015.snappy.parquet
```

Import the data using stream load:

```
curl --location-trusted -u root: -T amazon_reviews_2010.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
curl --location-trusted -u root: -T amazon_reviews_2011.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
curl --location-trusted -u root: -T amazon_reviews_2012.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
curl --location-trusted -u root: -T amazon_reviews_2013.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
```

```
curl --location-trusted -u root: -T amazon_reviews_2014.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
curl --location-trusted -u root: -T amazon_reviews_2015.snappy.parquet -H "format:parquet"
http://127.0.0.1:8030/api/${DB}/amazon_reviews/_stream_load
```

The data file may exceed 10 GB, and you may need to adjust the `streaming_load_max_mb` in `be.conf` to prevent exceeding the upload size limit of the stream load. You can dynamically adjust it by following the steps below:

```
curl -X POST http://{be_ip}:{be_http_port}/api/update_config?streaming_load_max_mb=32768
```

Every BE needs to execute the above command.

**Run a count query to confirm successful data import:**

```
mysql> SELECT COUNT(*) FROM amazon_reviews;
+-----+
| count(*) |
+-----+
| 135589433 |
+-----+
```

## Querying

First, run the query without any index. The WHERE clause contains a LIKE condition, and the query takes 7.60 seconds:

```
SELECT
 product_id,
 any_value(product_title),
 AVG(star_rating) AS rating,
 COUNT(*) AS count
FROM
 amazon_reviews
WHERE
 review_body LIKE '%is super awesome%'
GROUP BY
 product_id
ORDER BY
 count DESC,
 rating DESC,
 product_id
LIMIT 5;
```

**Results:**

product_id	any_value(product_title)	rating	count
B00992CF6W	Minecraft	4.8235294117647056	17
B009UX2YAC	Subway Surfers	4.777777777777777	9
B00DJFIMW6	Minion Rush: Despicable Me Official Game	4.875	8
B0086700CM	Temple Run	5	6

product_id	any_value(product_title)	rating	count
B00KWVZ750	Angry Birds Epic RPG	5	6

5 rows in set (7.60 sec)

Next, add an NGram BloomFilter index and run the same query again. The query takes 0.93 seconds, an 8x performance improvement:

```
ALTER TABLE amazon_reviews ADD INDEX review_body_ngram_idx(review_body) USING NGRAM_BF
PROPERTIES("gram_size"="10", "bf_size"="10240");
```

product_id	any_value(product_title)	rating	count
B00992CF6W	Minecraft	4.8235294117647056	17
B009UX2YAC	Subway Surfers	4.777777777777777	9
B00DJFIMW6	Minion Rush: Despicable Me Official Game	4.875	8
B0086700CM	Temple Run	5	6
B00KWVZ750	Angry Birds Epic RPG	5	6

5 rows in set (0.93 sec)

# Schema Change

Users can modify the schema of Doris tables through the [Alter Table](#) operation. Schema changes mainly involve column modifications and index changes. This article mainly introduces column-related schema changes; for index-related changes, please refer to [Table Index](#) to understand the different methods of changing indexes.

## Principles Introduction

Doris supports two types of schema change operations: lightweight schema change and heavyweight schema change. The differences mainly lie in the complexity of the execution process, execution speed, and resource consumption.

Feature	Lightweight Schema Change	Heavyweight Schema Change
Execution Speed	Seconds (almost real-time)	Minutes, hours, days (depends on the amount of data in the table; the larger the data, the slower the execution)
Data Rewrite Needed	No	Yes, involves rewriting data files
System Performance Impact	Minimal	May impact system performance, especially during data conversion
Resource Consumption	Low	High, will consume computing resources to reorganize data, and the storage space occupied by the table's data involved in the process will double.
Operation Types	Add, delete value columns, rename columns, modify VARCHAR length	Modify column data types, change primary keys, modify column order, etc.

## Lightweight Schema Change

Lightweight schema change refers to simple schema modification operations that do not involve data rewriting. These operations are usually performed at the metadata level and only require modifying the table's metadata without involving physical modifications to data files. Lightweight schema change operations can typically be completed in seconds and do not significantly impact system performance. Lightweight schema changes include:

- Adding or deleting value columns
- Renaming columns
- Modifying the length of VARCHAR columns (except for UNIQUE and DUP table key columns).

## Heavyweight Schema Change

Heavyweight schema change involves rewriting or converting data files, and these operations are relatively complex, usually requiring the assistance of Doris's Backend (BE) to perform actual data modifications or reorganizations. Heavyweight schema change operations typically involve deep changes to the table's data

structure and may affect the physical layout of storage. All operations that do not support lightweight schema changes fall under heavyweight schema changes, such as:

- Changing the data type of a column
- Modifying the order of columns

Heavyweight operations will start a task in the background for data conversion. The background task will convert each tablet of the table, rewriting the original data into new data files on a tablet basis. During the data conversion process, a “double write” phenomenon may occur, where new data is simultaneously written to both the new tablet and the old tablet. After the data conversion is complete, the old tablet will be deleted, and the new tablet will replace it.

## Job Management

### View Jobs

Users can view the progress of schema change jobs through the [SHOW ALTER TABLE COLUMN](#) command. This command allows users to see the currently executing or completed schema change jobs. When a schema change job involves materialized views, this command will display multiple rows, each corresponding to a materialized view. An example is as follows:

```
mysql > SHOW ALTER TABLE COLUMN\G;
***** 1. row *****
 JobId: 20021
 TableName: tbl1
 CreateTime: 2019-08-05 23:03:13
 FinishTime: 2019-08-05 23:03:42
 IndexName: tbl1
 IndexId: 20022
 OriginIndexId: 20017
 SchemaVersion: 2:792557838
 TransactionId: 10023
 State: FINISHED
 Msg:
 Progress: NULL
 Timeout: 86400
1 row in set (0.00 sec)
```

### Cancel Jobs

If the job status is not FINISHED or CANCELLED, you can cancel the schema change job using the following command:

```
CANCEL ALTER TABLE COLUMN FROM tbl_name;
```

## Usage Examples

### Rename Column

```
ALTER TABLE [database.]table RENAME COLUMN old_column_name new_column_name;
```

For specific syntax, refer to [ALTER TABLE RENAME](#).

## Add a Column

- If an aggregate model adds a value column, the `agg_type` must be specified.
- If a non-aggregate model (such as `DUPLICATE KEY`) adds a key column, the `KEY` keyword must be specified.

### *Adding a column to a non-aggregate table*

#### 1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 col1 int,
 col2 int,
 col3 int,
 col4 int,
 col5 int
) DUPLICATE KEY(col1, col2, col3)
DISTRIBUTED BY RANDOM BUCKETS 10;
```

#### 2. Add a key column `key_col` after `col1` in `example_db.my_table`

```
ALTER TABLE example_db.my_table ADD COLUMN key_col INT KEY DEFAULT "0" AFTER col1;
```

#### 3. Add a value column `value_col` after `col4` in `example_db.my_table`

```
ALTER TABLE example_db.my_table ADD COLUMN value_col INT DEFAULT "0" AFTER col4;
```

### *Adding a column to an aggregate table*

#### 1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 col1 int,
 col2 int,
 col3 int,
 col4 int SUM,
 col5 varchar(32) REPLACE DEFAULT "abc"
) AGGREGATE KEY(col1, col2, col3)
DISTRIBUTED BY HASH(col1) BUCKETS 10;
```

#### 2. Add a key column `key_col` after `col1` in `example_db.my_table`

```
ALTER TABLE example_db.my_table ADD COLUMN key_col INT DEFAULT "0" AFTER col1;
```

#### 3. Add a value column `value_col` of `SUM` aggregation type after `col4` in `example_db.my_table`

```
ALTER TABLE example_db.my_table ADD COLUMN value_col INT SUM DEFAULT "0" AFTER col4;
```

## Add Multiple Columns

- If an aggregate model adds a value column, the `agg_type` must be specified.
- If an aggregate model adds a key column, the `KEY` keyword must be specified.

### *Adding multiple columns to an aggregate table*

#### 1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 col1 int,
 col2 int,
 col3 int,
 col4 int SUM,
 col5 varchar(32) REPLACE DEFAULT "abc"
) AGGREGATE KEY(col1, col2, col3)
DISTRIBUTED BY HASH(col1) BUCKETS 10;
```

#### 2. Add multiple columns to `example_db.my_table` (aggregate model)

```
ALTER TABLE example_db.my_table
ADD COLUMN (c1 INT DEFAULT "1", c2 FLOAT SUM DEFAULT "0");
```

## Delete Column

- Partition columns cannot be deleted.
- `UNIQUE` key columns cannot be deleted.

To delete a column from `example_db.my_table`

#### 1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 col1 int,
 col2 int,
 col3 int,
 col4 int SUM,
 col5 varchar(32) REPLACE DEFAULT "abc"
) AGGREGATE KEY(col1, col2, col3)
DISTRIBUTED BY HASH(col1) BUCKETS 10;
```

#### 2. Delete the `col4` column from `example_db.my_table`

```
ALTER TABLE example_db.my_table DROP COLUMN col4;
```

## Modify Column Type and Position

- If an aggregate model modifies a value column, the `agg_type` must be specified.
- If a non-aggregate type modifies a key column, the **KEY** keyword must be specified.

- Only the type of the column can be modified; other attributes of the column must remain the same.
- Partition columns and bucket columns cannot be modified.
- The following type conversions are currently supported (users need to be aware of precision loss):
  - TINYINT/SMALLINT/INT/BIGINT/LARGEINT/FLOAT/DOUBLE types can be converted to larger numeric types.
  - TINYINT/SMALLINT/INT/BIGINT/LARGEINT/FLOAT/DOUBLE/DECIMAL can be converted to VARCHAR.
  - VARCHAR supports modifying the maximum length.
  - VARCHAR/CHAR can be converted to TINYINT/SMALLINT/INT/BIGINT/LARGEINT/FLOAT/DOUBLE.
  - VARCHAR/CHAR can be converted to DATE (currently supports six formats: "%Y-%m-%d", "%y-%m-%d", "%Y%m%d", "%y%m%d", "%Y/%m/%d", "%y/%m/%d").
  - DATETIME can be converted to DATE (only retains year-month-day information, e.g., 2019-12-09 21:47:05 <=> 2019-12-09).
  - DATE can be converted to DATETIME (hours, minutes, and seconds are automatically set to zero, e.g., 2019-12-09 <=> 2019-12-09 00:00:00).
  - FLOAT can be converted to DOUBLE.
  - INT can be converted to DATE (if the INT type data is invalid, the conversion fails, and the original data remains unchanged).
  - All types except DATE and DATETIME can be converted to STRING, but STRING cannot be converted to any other type.

## 1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 col0 int,
 col1 int DEFAULT "1",
 col2 int,
 col3 varchar(32),
 col4 int SUM,
 col5 varchar(32) REPLACE DEFAULT "abc"
) AGGREGATE KEY(col0, col1, col2, col3)
DISTRIBUTED BY HASH(col0) BUCKETS 10;
```

## 2. Modify the type of key column col1 to BIGINT and move it after column col2

```
ALTER TABLE example_db.my_table
MODIFY COLUMN col1 BIGINT KEY DEFAULT "1" AFTER col2;
```

Note: Whether modifying a key column or a value column, the complete column information must be declared.

3. Modify the maximum length of the val5 column in the base table. The original val5 was (val5 VARCHAR(32) REPLACE DEFAULT "abc")

```
ALTER TABLE example_db.my_table
MODIFY COLUMN col5 VARCHAR(64) REPLACE DEFAULT "abc";
```

Note: Only the type of the column can be modified; other attributes of the column must remain the same.

4. Modify the length of a field in a key column

```
ALTER TABLE example_db.my_table
MODIFY COLUMN col3 varchar(50) KEY NULL comment 'to 50';
```

## Reorder

- All columns must be listed.
- Value columns must be after key columns.

1. Create table statement

```
CREATE TABLE IF NOT EXISTS example_db.my_table(
 k1 int DEFAULT "1",
 k2 int,
 k3 varchar(32),
 k4 date,
 v1 int SUM,
 v2 int MAX,
) AGGREGATE KEY(k1, k2, k3, k4)
DISTRIBUTED BY HASH(k1) BUCKETS 10;
```

2. Reorder the columns in example\_db.my\_table

```
ALTER TABLE example_db.my_table
ORDER BY (k3,k1,k2,k4,v2,v1);
```

## Limitations

- A table can only have one schema change job running at the same time.
- Partition columns and bucket columns cannot be modified.
- If an aggregate table has value columns aggregated using the REPLACE method, key columns cannot be deleted.
- Unique tables cannot delete key columns.
- When adding value columns with aggregation types of SUM or REPLACE, the default value of that column has no meaning for historical data.
- Because historical data has lost detailed information, the value of the default cannot actually reflect the aggregated value.

- When modifying column types, all fields except Type must be supplemented with the original column's information.
- Note that, except for the new column type, aggregation method, Nullable attribute, and default value must be supplemented according to the original information.
- Modifying aggregation types, Nullable attributes, and default values is not supported.

## Related Configurations

### FE Configuration

- `alter_table_timeout_second`: The default timeout for jobs, 86400 seconds.

### BE Configuration

- `alter_tablet_worker_count`: The number of threads used on the BE side to execute historical data conversion. The default is 3. If you want to speed up schema change jobs, you can appropriately increase this parameter and restart BE. However, too many conversion threads may increase IO pressure and affect other operations.
- `alter_index_worker_count`: The number of threads used on the BE side to execute historical data index building (Note: currently only supports inverted indexes). The default is 3. If you want to speed up index change jobs, you can appropriately increase this parameter and restart BE. However, too many threads may increase IO pressure and affect other operations.

# Auto-Increment Column

---

In Doris, the auto increment column is a feature that automatically generates a unique numeric value, commonly used to create unique identifiers for each row of data, such as primary keys. Each time a new record is inserted, the auto increment column automatically assigns an incrementing value, eliminating the need for manually specifying the number. By using Doris's auto increment column, data uniqueness and consistency are ensured, simplifying the data insertion process, reducing human error, and improving data management efficiency. This makes the auto increment column an ideal choice for scenarios requiring unique identifiers, such as user IDs and more.

## Functionality

For tables with an auto-increment column, Doris processes data writes as follows:

- **Auto-Population (Column Excluded):** If the written data does not include the auto-increment column, Doris generates and populates unique values for this column.
- **Partial Specification (Column Included):**
  - **Null Values:** Doris replaces null values in the written data with system-generated unique values.
  - **Non-Null Values:** User-provided values remain unchanged.

:::caution Attention User-provided non-null values can disrupt the uniqueness of the auto-increment column. :::

## Uniqueness

Doris guarantees **table-wide uniqueness** for values it generates in the auto-increment column. However:

- **Guaranteed Uniqueness:** This applies only to system-generated values.
- **User-Provided Values:** Doris does not validate or enforce uniqueness for values specified by users in the auto-increment column. This may result in duplicate entries.

## Density

Auto-increment values generated by Doris are generally **dense** but with some considerations:

- **Potential Gaps:** Gaps may appear due to performance optimizations. Each backend node (BE) pre-allocates a block of unique values for efficiency, and these blocks do not overlap between nodes.
- **Non-Chronological Values:** Doris does not guarantee that values generated in later writes are larger than those from earlier writes.

:::info Note Auto-increment values cannot be used to infer the chronological order of writes. :::

## Syntax

To use auto-increment columns, you need to add the `AUTO_INCREMENT` attribute to the corresponding column during table creation ([CREATE-TABLE](#)). To manually specify the starting value for an auto-increment column, you can do so by using the `AUTO_INCREMENT(start_value)` statement when creating the table. If not specified, the default starting value is 1.

## Examples

1. Creating a duplicate table with an auto-increment column as the key column.

```
CREATE TABLE `demo`.`tbl` (
 `id` BIGINT NOT NULL AUTO_INCREMENT,
 `value` BIGINT NOT NULL
) ENGINE=OLAP
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 10
PROPERTIES (
 "replication_allocation" = "tag.location.default: 3"
);
```

2. Creating a duplicate table with an auto-increment column as the key column, and setting the starting value to 100.

```
```sql  
CREATE TABLE `demo`.`tbl` (  
  `id` BIGINT NOT NULL AUTO_INCREMENT(100),  
  `value` BIGINT NOT NULL  
) ENGINE=OLAP  
DUPLICATE KEY(`id`)  
DISTRIBUTED BY HASH(`id`) BUCKETS 10  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 3"  
);
```

3. Creating a duplicate table with an auto-increment column as one of the value columns.

```
CREATE TABLE `demo`.`tbl` (  
  `uid` BIGINT NOT NULL,  
  `name` BIGINT NOT NULL,  
  `id` BIGINT NOT NULL AUTO_INCREMENT,  
  `value` BIGINT NOT NULL  
) ENGINE=OLAP  
DUPLICATE KEY(`uid`, `name`)  
DISTRIBUTED BY HASH(`uid`) BUCKETS 10  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 3"  
);
```

4. Creating a unique table with an auto-increment column as the key column.

```
CREATE TABLE `demo`.`tbl` (  
  `id` BIGINT NOT NULL AUTO_INCREMENT,  
  `name` varchar(65533) NOT NULL,  
  `value` int(11) NOT NULL  
) ENGINE=OLAP  
UNIQUE KEY(`id`)
```

```
DISTRIBUTED BY HASH(`id`) BUCKETS 10
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"enable_unique_key_merge_on_write" = "true"
);
```

5. Creating a unique table with an auto-increment column as one of the value columns.

```
CREATE TABLE `demo`.`tbl` (
  `text` varchar(65533) NOT NULL,
  `id` BIGINT NOT NULL AUTO_INCREMENT,
) ENGINE=OLAP
UNIQUE KEY(`text`)
DISTRIBUTED BY HASH(`text`) BUCKETS 10
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"enable_unique_key_merge_on_write" = "true"
);
```

Constraints and Limitations

- Auto-increment columns can only be used in Duplicate or Unique model tables.
- A table can have only one auto-increment column.
- The auto-increment column must be of type BIGINT and cannot be NULL.
- The manually specified starting value for an auto-increment column must be 0 or greater.

Usage

Loading

Consider the table below:

```
CREATE TABLE `demo`.`tbl` (
  `id` BIGINT NOT NULL AUTO_INCREMENT,
  `name` varchar(65533) NOT NULL,
  `value` int(11) NOT NULL
) ENGINE=OLAP
UNIQUE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 10
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"enable_unique_key_merge_on_write" = "true"
);
```

When using the insert into statement to write data without including the auto-increment column `id`, Doris automatically generates and fills unique values for the column.

```
insert into tbl(name, value) values("Bob", 10), ("Alice", 20), ("Jack", 30);

select * from tbl order by id;
+-----+-----+-----+
| id   | name | value |
+-----+-----+-----+
| 1    | Bob  | 10    |
| 2    | Alice| 20    |
```

3	Jack	30
---	------	----

Similarly, when using stream load to load the file `test.csv` without specifying the auto-increment column `id`, Doris will automatically populate the `id` column with generated values.

`test.csv`:

```
Tom, 40
John, 50
```

```
curl --location-trusted -u user:passwd -H "columns:name,value" -H "column_separator:," -T ./test1.csv
http://{host}:{port}/api/{db}/tbl/_stream_load
```

```
select * from tbl order by id;
+-----+-----+-----+
| id  | name | value |
+-----+-----+-----+
| 1  | Bob  | 10    |
| 2  | Alice| 20    |
| 3  | Jack | 30    |
| 4  | Tom  | 40    |
| 5  | John | 50    |
+-----+-----+-----+
```

When writing data using the `INSERT INTO` statement and specifying the auto-increment column `id`, any null values in the written data for that column will be replaced with generated values.

```
insert into tbl(id, name, value) values(null, "Doris", 60), (null, "Nereids", 70);

select * from tbl order by id;
+-----+-----+-----+
| id  | name  | value |
+-----+-----+-----+
| 1  | Bob   | 10    |
| 2  | Alice | 20    |
| 3  | Jack  | 30    |
| 4  | Tom   | 40    |
| 5  | John  | 50    |
| 6  | Doris | 60    |
| 7  | Nereids | 70   |
+-----+-----+-----+
```

Partial Update

When performing a partial update on a merge-on-write Unique table with an auto-increment column:

If the auto-increment column is a key column, users must explicitly specify it during partial updates. As a result, the target columns for partial updates must include the auto-increment column. In this case, the behavior aligns with that of standard partial updates.

```
CREATE TABLE `demo`.`tbl2` (
  `id` BIGINT NOT NULL AUTO_INCREMENT,
  `name` varchar(65533) NOT NULL,
```

```

`value` int(11) NOT NULL DEFAULT "0"
) ENGINE=OLAP
UNIQUE KEY(`id`)

| 4 | added | 0 |
+-----+-----+-----+

```

When the auto-increment column is a non-key column and no value is provided, its value will be derived from existing rows in the table. If a value is specified for the auto-increment column, null values in the written data will be replaced with generated values, while non-null values will remain unchanged. These records will then be processed according to the semantics of partial updates.

```

CREATE TABLE `demo`.`tbl3` (
  `id` BIGINT NOT NULL,
  `name` varchar(100) NOT NULL,
  `score` BIGINT NOT NULL,
  `aid` BIGINT NOT NULL AUTO_INCREMENT
) ENGINE=OLAP
UNIQUE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
"replication_allocation" = "tag.location.default: 3",
"enable_unique_key_merge_on_write" = "true"
);

insert into tbl3(id, name, score) values(1, "Doris", 100), (2, "Nereids", 200), (3, "Bob", 300);

select * from tbl3 order by id;
+-----+-----+-----+-----+
| id | name | score | aid |

+-----+-----+-----+-----+
| 1   | Doris | 999   | 1000 |
| 2   | Nereids | 888   | 1    |
| 3   | Bob   | 300   | 500  |
+-----+-----+-----+-----+

```

Usage Scenarios

Dictionary Encoding

Using bitmaps for audience analysis in user profiling involves creating a user dictionary, where each user is assigned a unique integer as their dictionary value. Aggregating these dictionary values can improve the performance of bitmap operations.

For example, in an offline UV (Unique Visitors) and PV (Page Views) analysis scenario, consider a detailed user behavior table:

```

CREATE TABLE `demo`.`dwd_dup_tbl` (
  `user_id` varchar(50) NOT NULL,
  `dim1` varchar(50) NOT NULL,
  `dim2` varchar(50) NOT NULL,
  `dim3` varchar(50) NOT NULL,
  `dim4` varchar(50) NOT NULL,
  `dim5` varchar(50) NOT NULL,
  `visit_time` DATE NOT NULL
) ENGINE=OLAP
DUPLICATE KEY(`user_id`)
DISTRIBUTED BY HASH(`user_id`) BUCKETS 32
PROPERTIES (
  "replication_allocation" = "tag.location.default: 3"
);

```

Using the auto-increment column to create the following dictionary table:

```

CREATE TABLE `demo`.`dictionary_tbl` (
  `user_id` varchar(50) NOT NULL,

```

```

    `aid` BIGINT NOT NULL AUTO_INCREMENT
) ENGINE=OLAP
UNIQUE KEY(`user_id`)
DISTRIBUTED BY HASH(`user_id`) BUCKETS 32
PROPERTIES (
    "replication_allocation" = "tag.location.default: 3",
    "enable_unique_key_merge_on_write" = "true"
);

```

Write the `user_id` values from existing data into the dictionary table to map `user_id` to corresponding integer values:

```

insert into dictionary_tbl(user_id)
select user_id from dwd_dup_tbl group by user_id;

```

Alternatively, write only the `user_id` values from incremental data into the dictionary table.

```

insert into dictionary_tbl(user_id)
select dwd_dup_tbl.user_id from dwd_dup_tbl left join dictionary_tbl
on dwd_dup_tbl.user_id = dictionary_tbl.user_id where dwd_dup_tbl.visit_time > '2023-12-10' and
dictionary_tbl.user_id is NULL;

```

In practical applications, Flink connectors can be used to write data into Doris.

To store aggregated results for the statistical dimensions `dim1`, `dim3`, and `dim5`, create the following table:

```

CREATE TABLE `demo`.`dws_agg_tbl` (
    `dim1` varchar(50) NOT NULL,
    `dim3` varchar(50) NOT NULL,
    `dim5` varchar(50) NOT NULL,
    `user_id_bitmap` BITMAP BITMAP_UNION NOT NULL,
    `pv` BIGINT SUM NOT NULL
) ENGINE=OLAP
AGGREGATE KEY(`dim1`,`dim3`,`dim5`)
DISTRIBUTED BY HASH(`user_id`) BUCKETS 32
PROPERTIES (
    "replication_allocation" = "tag.location.default: 3"
);

```

Save the aggregated data into the results table.

```

insert into dws_agg_tbl
select dwd_dup_tbl.dim1, dwd_dup_tbl.dim3, dwd_dup_tbl.dim5, BITMAP_UNION(TO_BITMAP(dictionary_tbl.aid)),
COUNT(1)
from dwd_dup_tbl INNER JOIN dictionary_tbl on dwd_dup_tbl.user_id = dictionary_tbl.user_id;

```

Execute UV and PV queries with the following statement:

```

select dim1, dim3, dim5, user_id_bitmap as uv, pv from dws_agg_tbl;

```

Efficient Pagination

Pagination is often required when displaying data on a page. Traditional pagination usually involves using LIMIT, OFFSET, and ORDER BY in SQL queries. For example, consider the following business table designed for display:

```
CREATE TABLE `demo`.`records_tbl` (  
  `key` int(11) NOT NULL COMMENT "",  
  `name` varchar(26) NOT NULL COMMENT "",  
  `address` varchar(41) NOT NULL COMMENT "",  
  `city` varchar(11) NOT NULL COMMENT "",  
  `nation` varchar(16) NOT NULL COMMENT "",  
  `region` varchar(13) NOT NULL COMMENT "",  
  `phone` varchar(16) NOT NULL COMMENT "",  
  `mktsegment` varchar(11) NOT NULL COMMENT ""  
) DUPLICATE KEY (`key`, `name`)  
DISTRIBUTED BY HASH(`key`) BUCKETS 10  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 3"  
);
```

Assuming 100 records are displayed per page, the following SQL query can be used to fetch data for the first page:

```
select * from records_tbl order by `key`, `name` limit 100;
```

To fetch data for the second page, you can use the following query:

```
select * from records_tbl order by `key`, `name` limit 100 offset 100;
```

However, when performing deep pagination queries (with large offsets), this method can be inefficient, as it reads all data into memory for sorting before processing, even if only a small number of rows are needed. By using an auto-increment column, each row is assigned a unique value, enabling the use of a query like WHERE unique_value > x LIMIT y to filter out a large portion of the data in advance, making pagination more efficient.

To illustrate this, an auto-increment column is added to the business table, giving each row a unique identifier:

```
CREATE TABLE `demo`.`records_tbl2` (  
  `key` int(11) NOT NULL COMMENT "",  
  `name` varchar(26) NOT NULL COMMENT "",  
  `address` varchar(41) NOT NULL COMMENT "",  
  `city` varchar(11) NOT NULL COMMENT "",  
  `nation` varchar(16) NOT NULL COMMENT "",  
  `region` varchar(13) NOT NULL COMMENT "",  
  `phone` varchar(16) NOT NULL COMMENT "",  
  `mktsegment` varchar(11) NOT NULL COMMENT "",  
  `unique_value` BIGINT NOT NULL AUTO_INCREMENT  
) DUPLICATE KEY (`key`, `name`)  
DISTRIBUTED BY HASH(`key`) BUCKETS 10  
PROPERTIES (  
  "replication_num" = "3"  
);
```

For pagination with 100 records per page, the following SQL query can be used to fetch the data for the first page:

```
select * from records_tbl2 order by unique_value limit 100;
```

By recording the maximum value of `unique_value` from the returned results, let's assume it is 99. The following query can then be used to fetch data for the second page:

```
select * from records_tbl2 where unique_value > 99 order by unique_value limit 100;
```

If directly querying data from a later page and it's inconvenient to retrieve the maximum value of `unique_value` from the previous page's results (for example, when fetching data starting from the 101st page), the following query can be used:

```
select key, name, address, city, nation, region, phone, mktsegment
from records_tbl2, (select unique_value as max_value from records_tbl2 order by unique_value limit 1 offset
9999) as previous_data
where records_tbl2.unique_value > previous_data.max_value
order by records_tbl2.unique_value limit 100;
```

Tiered Storage Overview

To help users reduce storage costs, Doris provides flexible options for cold data management.

Cold Data Options	Applicable Conditions	Features
Compute-Storage Separation	Users have the capability to deploy a compute-storage separation setup	<ul style="list-style-type: none">- Data is stored as a single replica in object storage- Local caching accelerates hot data access- Independent scaling of storage and compute resources significantly reduces costs
Local Tiering	In the compute-storage integrated mode, users want to further optimize local storage resources	<ul style="list-style-type: none">- Supports cooling cold data from SSD to HDD- Fully utilizes the tiered characteristics of local storage to save high-performance storage costs
Remote Tiering	In the compute-storage integrated mode, users want to reduce costs using affordable object storage or HDFS	<ul style="list-style-type: none">- Cold data is stored as a single replica in object storage or HDFS- Hot data continues to use local storage- Cannot be combined with local tiering for the same table

With the above options, Doris can flexibly adapt to different deployment scenarios, achieving a balance between query efficiency and storage cost.

Tiered Storage of SSD and HDD

Doris supports tiered storage between different disk types (SSD and HDD), combining dynamic partitioning features to dynamically migrate data from SSD to HDD based on the characteristics of hot and cold data. This approach reduces storage costs while maintaining high performance for hot data reads and writes.

Dynamic Partitioning and Tiered Storage

By configuring dynamic partitioning parameters of a table, users can set which partitions are stored on SSD and automatically migrate to HDD after cooling.

- **Hot Partitions:** Recently active partitions, prioritized to be stored on SSD to ensure high performance.
- **Cold Partitions:** Partitions that are accessed less frequently, which will gradually migrate to HDD to reduce storage costs.

For more information on dynamic partitioning, please refer to: [Data Partitioning - Dynamic Partitioning](#).

Parameter Description

`dynamic_partition.hot_partition_num`

- **Function:**
 - Specifies how many of the most recent partitions are hot partitions, which are stored on SSD, while the remaining partitions are stored on HDD.
- **Note:**
 - `"dynamic_partition.storage_medium" = "HDD"` must be set simultaneously; otherwise, this parameter will not take effect.
 - If there are no SSD devices in the storage path, this configuration will cause partition creation to fail.

Example Description:

Assuming the current date is **2021-05-20**, with daily partitioning, the dynamic partitioning configuration is as follows:

```
"dynamic_partition.time_unit" = "DAY",  
"dynamic_partition.hot_partition_num" = 2  
"dynamic_partition.start" = -3  
"dynamic_partition.end" = 3
```

The system will automatically create the following partitions and configure their storage medium and cooling time:

```
p20210517: ["2021-05-17", "2021-05-18") storage_medium=HDD storage_cooldown_time=9999-12-31 23:59:59  
p20210518: ["2021-05-18", "2021-05-19") storage_medium=HDD storage_cooldown_time=9999-12-31 23:59:59  
p20210519: ["2021-05-19", "2021-05-20") storage_medium=SSD storage_cooldown_time=2021-05-21 00:00:00  
p20210520: ["2021-05-20", "2021-05-21") storage_medium=SSD storage_cooldown_time=2021-05-22 00:00:00  
p20210521: ["2021-05-21", "2021-05-22") storage_medium=SSD storage_cooldown_time=2021-05-23 00:00:00
```

```
p20210522: ["2021-05-22", "2021-05-23") storage_medium=SSD storage_cooldown_time=2021-05-24 00:00:00
p20210523: ["2021-05-23", "2021-05-24") storage_medium=SSD storage_cooldown_time=2021-05-25 00:00:00
```

dynamic_partition.storage_medium

- **Function:**
 - Specifies the final storage medium for dynamic partitions. The default is HDD, but SSD can be selected.
- **Note:**
 - When set to SSD, the hot_partition_num attribute will no longer take effect, and all partitions will default to SSD storage medium with a cooling time of 9999-12-31 23:59:59.

Example

1. Create a table with dynamic_partition

```
CREATE TABLE tiered_table (k DATE)
PARTITION BY RANGE(k)()
DISTRIBUTED BY HASH (k) BUCKETS 5
PROPERTIES
(
    "dynamic_partition.storage_medium" = "hdd",
    "dynamic_partition.enable" = "true",
    "dynamic_partition.time_unit" = "DAY",
    "dynamic_partition.hot_partition_num" = "2",
    "dynamic_partition.end" = "3",
    "dynamic_partition.prefix" = "p",
    "dynamic_partition.buckets" = "5",
    "dynamic_partition.create_history_partition" = "true",
    "dynamic_partition.start" = "-3"
);
```

2. Check storage medium of partitions

```
SHOW PARTITIONS FROM tiered_table;
```

You should have 7 partitions, 5 of which use SSD as the storage medium, while the other 2 use HDD.

```
p20210517: ["2021-05-17", "2021-05-18") storage_medium=HDD storage_cooldown_time=9999-12-31 23:59:59
p20210518: ["2021-05-18", "2021-05-19") storage_medium=HDD storage_cooldown_time=9999-12-31 23:59:59
p20210519: ["2021-05-19", "2021-05-20") storage_medium=SSD storage_cooldown_time=2021-05-21 00:00:00
p20210520: ["2021-05-20", "2021-05-21") storage_medium=SSD storage_cooldown_time=2021-05-22 00:00:00
p20210521: ["2021-05-21", "2021-05-22") storage_medium=SSD storage_cooldown_time=2021-05-23 00:00:00
p20210522: ["2021-05-22", "2021-05-23") storage_medium=SSD storage_cooldown_time=2021-05-24 00:00:00
p20210523: ["2021-05-23", "2021-05-24") storage_medium=SSD storage_cooldown_time=2021-05-25 00:00:00
```

Remote Storage

Overview

Remote storage supports placing cold data in external storage (such as object storage, HDFS).

Note

The data in remote storage has only one copy, and the reliability of the data depends on the reliability of the remote storage. You need to ensure that the remote storage has erasure coding (EC) or multi-replica technology to ensure data reliability.

Usage

Saving Cold Data to S3 Compatible Storage

Step 1: Create S3 Resource.

```
CREATE RESOURCE "remote_s3"
PROPERTIES
(
  "type" = "s3",
  "s3.endpoint" = "bj.s3.com",
  "s3.region" = "bj",
  "s3.bucket" = "test-bucket",
  "s3.root.path" = "path/to/root",
  "s3.access_key" = "bbb",
  "s3.secret_key" = "aaaa",
  "s3.connection.maximum" = "50",
  "s3.connection.request.timeout" = "3000",
  "s3.connection.timeout" = "1000"
);
```

When creating the S3 RESOURCE, a link verification to the S3 remote will be performed to ensure the correctness of the RESOURCE creation.

Step 2: Create STORAGE POLICY.

Then create a STORAGE POLICY associated with the RESOURCE created above:

```
CREATE STORAGE POLICY test_policy
PROPERTIES(
  "storage_resource" = "remote_s3",
  "cooldown_ttl" = "1d"
);
```

Step 3: Use STORAGE POLICY when creating a table.

```
CREATE TABLE IF NOT EXISTS create_table_use_created_policy
(
    k1 BIGINT,
    k2 LARGEINT,
    v1 VARCHAR(2048)
)
UNIQUE KEY(k1)
DISTRIBUTED BY HASH (k1) BUCKETS 3
PROPERTIES(
    "enable_unique_key_merge_on_write" = "false",
    "storage_policy" = "test_policy"
);
```

Note

If the UNIQUE table is set with "enable_unique_key_merge_on_write" = "true", this feature cannot be used.

Saving Cold Data to HDFS

Step 1: Create HDFS RESOURCE:

```
CREATE RESOURCE "remote_hdfs" PROPERTIES (
    "type"="hdfs",
    "fs.defaultFS"="fs_host:default_fs_port",
    "hadoop.username"="hive",
    "hadoop.password"="hive",
    "root_path"="/my/root/path",
    "dfs.nameservices" = "my_ha",
    "dfs.ha.namenodes.my_ha" = "my_namenode1, my_namenode2",
    "dfs.namenode.rpc-address.my_ha.my_namenode1" = "nn1_host:rpc_port",
    "dfs.namenode.rpc-address.my_ha.my_namenode2" = "nn2_host:rpc_port",
    "dfs.client.failover.proxy.provider.my_ha" =
"org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
);
```

Step 2: Create STORAGE POLICY.

```
CREATE STORAGE POLICY test_policy PROPERTIES (
    "storage_resource" = "remote_hdfs",
    "cooldown_ttl" = "300"
)
```

Step 3: Use STORAGE POLICY to create a table.

```
CREATE TABLE IF NOT EXISTS create_table_use_created_policy (
    k1 BIGINT,
    k2 LARGEINT,
    v1 VARCHAR(2048)
)
UNIQUE KEY(k1)
DISTRIBUTED BY HASH (k1) BUCKETS 3
```

```
PROPERTIES(  
  "enable_unique_key_merge_on_write" = "false",  
  "storage_policy" = "test_policy"  
);
```

Note

If the UNIQUE table is set with "enable_unique_key_merge_on_write" = "true", this feature cannot be used.

Cooling Existing Tables to Remote Storage

In addition to new tables supporting the setting of remote storage, Doris also supports setting remote storage for an existing table or PARTITION.

For an existing table, set remote storage by associating the created STORAGE POLICY with the table:

```
ALTER TABLE create_table_not_have_policy set ("storage_policy" = "test_policy");
```

For an existing PARTITION, set remote storage by associating the created STORAGE POLICY with the PARTITION:

```
ALTER TABLE create_table_partition MODIFY PARTITION (*) SET("storage_policy"="test_policy");
```

Note that if the user specifies different Storage Policies for the entire Table and some Partitions when creating the table, the Storage Policy set for the Partition will be ignored, and all Partitions of the table will use the table's Policy. If you need a Partition's Policy to differ from others, you can modify it using the method described above for associating a Storage Policy with an existing Partition.

For more details, please refer to the Docs directory under [RESOURCE](#), [STORAGE POLICY](#), [CREATE TABLE](#), [ALTER TABLE](#), etc.

Configuring Compaction

- The BE parameter cold_data_compaction_thread_num can set the concurrency for executing remote storage Compaction, with a default of 2.
- The BE parameter cold_data_compaction_interval_sec can set the time interval for executing remote storage Compaction, with a default of 1800 seconds, which is half an hour.

Limitations

- Tables using remote storage do not support backup.

- Modifying the location information of remote storage, such as endpoint, bucket, or path, is not supported.
- Unique model tables with Merge-on-Write enabled do not support remote storage.
- Storage policies support creation, modification, and deletion. Before deleting a storage policy, ensure that no tables are referencing it.
- Once a storage policy is set, it cannot be unset.

Cold Data Space

Viewing

Method 1: You can view the size uploaded to the object by each BE through `show proc '/backends'`, in the `RemoteUsedCapacity` item, this method has a slight delay.

Method 2: You can view the size of each tablet occupied by the table through `show tablets from tableName`, in the `RemoteDataSize` item.

Garbage Collection

There may be situations that generate garbage data on remote storage:

1. Rowset upload fails but some segments are successfully uploaded.
2. The uploaded rowset did not reach consensus in multiple replicas.
3. Rowsets participating in compaction after compaction is completed.

Garbage data will not be cleaned up immediately. The BE parameter `remove_unused_remote_files_interval_sec` can set the time interval for garbage collection on remote storage, with a default of 21600 seconds, which is 6 hours.

Query and Performance Optimization

To optimize query performance and save object storage resources, local Cache has been introduced. When querying data from remote storage for the first time, Doris will load the data from remote storage to the local disk of the BE for caching. The Cache has the following characteristics:

- The Cache is actually stored on the local disk of the BE and does not occupy memory space.
- The Cache is managed through LRU and does not support TTL.

For specific configurations, please refer to [Data Cache](#).

FAQ

1. `ERROR 1105 (HY000): errCode = 2, detailMessage = Failed to create repository: connect to s3 failed: Unable to marshall request to JSON: host must not be null.`

The S3 SDK defaults to using the virtual-hosted style method. However, some object storage systems (such as MinIO) may not have virtual-hosted style access enabled or supported. In this case, we can add the `use_path_style` parameter to force the use of the path style method:

```
CREATE RESOURCE "remote_s3"
PROPERTIES
(
  "type" = "s3",
  "s3.endpoint" = "bj.s3.com",
  "s3.region" = "bj",
  "s3.bucket" = "test-bucket",
  "s3.root.path" = "path/to/root",
  "s3.access_key" = "bbb",
  "s3.secret_key" = "aaaa",
  "s3.connection.maximum" = "50",
  "s3.connection.request.timeout" = "3000",
  "s3.connection.timeout" = "1000",
  "use_path_style" = "true"
);
```

2. What happens after modifying parameters related to cooldown time?

Changes to cooldown-related parameters only take effect for data that has not yet been cooled to remote storage. For data that has already been cooled to remote storage, the changes do not apply. For example, if you change `cooldown_ttl` from 21 days to 7 days, data that is already in remote storage will not be moved back to local storage;

Hybrid Row-Columnar Storage

Hybrid Row-Columnar Storage

Doris uses columnar storage by default, with each column stored contiguously. Columnar storage offers excellent performance for analytical scenarios (such as aggregation, filtering, sorting, etc.), as it only reads the necessary columns, reducing unnecessary IO. However, in point query scenarios (such as `SELECT *`), all columns need to be read, requiring an IO operation for each column, which can lead to IOPS becoming a bottleneck, especially for wide tables with many columns (e.g., hundreds of columns).

To address the IOPS bottleneck in point query scenarios, starting from version 2.0.0, Doris supports Hybrid Row-Columnar Storage. When users create tables, they can specify whether to enable row storage. With row storage enabled, each row only requires one IO operation for point queries (such as `SELECT *`), significantly improving performance.

The principle of row storage is that an additional column is added during storage. This column concatenates all the columns of the corresponding row and stores them using a special binary format.

Syntax

When creating a table, specify whether to enable row storage, and the storage compression unit size `page_size` in the table's `PROPERTIES`.

Property	Default	Description
"store_row_column"	false	Enable row storage for all columns.
"row_store_page_size"	16384 (16 KB)	Size of the row-store page in bytes.

A page is the smallest unit for storage read and write operations, and `page_size` refers to the size of a row-store page. This means that reading a single row requires generating a page IO. The larger this value is, the better the compression effect and the lower the storage space usage. However, the IO overhead during point queries increases, resulting in lower performance (because each IO operation reads at least one page). Conversely, the smaller the value, the higher the storage space usage and the better the performance for point queries. The default value of 16KB is a balanced choice in most cases. If you prioritize query performance, you can configure a smaller value, such as 4KB or even lower. If you prioritize storage space, you can configure a larger value, such as 64KB or even higher.

Version 2.1 does not support the `row_store_columns` property to specify partial columns for row storage.

Example

The example below creates an 8-column table with row storage enabled. To optimize for high-concurrency point query performance, the `row_store_page_size` is configured to 4KB.

```
CREATE TABLE `tbl_point_query` (
  `key` int(11) NULL,
  `v1` decimal(27, 9) NULL,
  `v2` varchar(30) NULL,
  `v3` varchar(30) NULL,
  `v4` date NULL,
  `v5` datetime NULL,
  `v6` float NULL,
  `v7` datev2 NULL
) ENGINE=OLAP
UNIQUE KEY(`key`)
COMMENT 'OLAP'
DISTRIBUTED BY HASH(`key`) BUCKETS 1
PROPERTIES (
  "enable_unique_key_merge_on_write" = "true",
  "light_schema_change" = "true",
  "store_row_column" = "true",
  "row_store_page_size" = "4096"
);
```

Query:

```
SELECT * FROM tbl_point_query WHERE key = 100;
```

For more information on point query usage, please refer to [High-Concurrent Point Query](#).

Notice

1. Enabling row storage will increase the storage space used. The increase in storage space is related to the data characteristics and is generally 2 to 10 times the size of the original table. The exact space usage needs to be tested with actual data.
2. The `page_size` of row storage also affects the storage space. You can adjust it based on the table attribute parameter `row_store_page_size`.
3. Modifying the `store_row_column` property via `ALTER TABLE` is not supported.

Best Practices | Table Design

Best Practices

Data models

Doris arranges data in three models: DUPLICATE KEY model, UNIQUE KEY model, and AGGREGATE KEY model.

****Recommendations****

Because the data model is determined and **immutable** during table creation, it is important to select the most suitable data model.

1. The Duplicate Key model is a good fit for ad-hoc queries across any dimensions. It cannot leverage the benefits of pre-aggregation, but it is also not constrained by the limitations of an aggregation model, so it can take advantage of columnar storage (only reading the relevant columns without the need to read all key columns).
2. The Aggregate Key model, through pre-aggregation, can largely reduce the amount of data scanned and the computational workload for aggregate queries. It is particularly suitable for reporting queries with fixed patterns. However, this model is not friendly for count(*) queries. Additionally, since the aggregation method on the Value columns are fixed, users should pay extra attention to semantic correctness when performing other types of aggregate queries.
3. The Unique Key model is designed for scenarios that require unique primary key constraints. It can ensure the uniqueness of primary keys. The downside is that it cannot reap the benefits brought by materialization and pre-aggregation. For users with high-performance requirements for aggregate queries, it is recommended to use the Merge-on-Write feature of the Unique Key model since Doris 1.2.
4. Users with partial column update requirements might select from the following data models:
 1. Unique Key model (Merge-on-Write mode)
 2. Aggregate Key model (aggregated by REPLACE_IF_NOT_NULL)

DUPLICATE KEY model

duplicate-key-model-example

When only the sorting columns are specified, rows with the same key will not be merged.

This is applicable to analytical business scenarios where data does not require pre-aggregation:

- Analysis of raw data
- Analysis of log or time series data where only new data is appended.

Best practice

```
-- For example, log analysis that allows only appending new data with replicated KEYS.
CREATE TABLE session_data
(
    visitorid SMALLINT,
    sessionid BIGINT,
    visittime DATETIME,
    city CHAR(20),
    province CHAR(20),
    ip VARCHAR(32),
    browser CHAR(20),
    url VARCHAR(1024)
)
DUPLICATE KEY(visitorid, sessionid) -- Used solely for specifying sorting columns, rows with the same KEY
will not be merged.
DISTRIBUTED BY HASH(sessionid, visitorid) BUCKETS 10;
```

AGGREGATE KEY model

aggregate-key-model-example

Old and new records with the same AGGREGATE KEY will be aggregated. The currently supported aggregation methods are as follows:

1. SUM: calculates the sum by accumulating the values of multiple rows;
2. REPLACE: replaces the value in the previously imported rows with the value from the next batch of data;
3. MAX: retains the maximum value;
4. MIN: retains the minimum value;
5. REPLACE_IF_NOT_NULL: replaces non-null values. Unlike REPLACE, it does not replace null values;
6. HLL_UNION: aggregates columns of HLL type using the HyperLogLog algorithm;
7. BITMAP_UNION: aggregates columns of BITMAP type using bitmap union aggregation;

This is suitable for reporting and multi-dimensional analysis scenarios such as:

- Website traffic analysis
- Multi-dimensional analysis of data reports.

Best practice

```
-- Example of website traffic analysis
CREATE TABLE site_visit
(
    siteid INT,
    city SMALLINT,
    username VARCHAR(32),
    pv BIGINT SUM DEFAULT '0' -- PV caculation
)
AGGREGATE KEY(siteid, city, username) -- Rows with the same KEY will be merged, and non-key columns will be
```

```
aggregated based on the specified aggregation function.  
DISTRIBUTED BY HASH(siteid) BUCKETS 10;
```

UNIQUE KEY model

The new record will replace the old record that has the same UNIQUE KEY with it. Before Doris 1.2, the UNIQUE KEY model was implemented the same way as the REPLACE aggregation of the AGGREGATE KEY model. However, Since Doris 1.2, we have introduced the Merge-on-Write implementation for the UNIQUE KEY model, which provides better performance for aggregate queries.

This is suitable for analytical business scenarios that require updates, such as:

- Deduplicated order analysis
- Real-time synchronization of inserts, updates, and deletes.

Best practice

```
-- Example of deduplicated order analysis  
CREATE TABLE sales_order  
(  
  orderid    BIGINT,  
  status     TINYINT,  
  username   VARCHAR(32),  
  amount     BIGINT DEFAULT '0'  
)  
UNIQUE KEY(orderid) -- Rows of the same KEY will be merged  
DISTRIBUTED BY HASH(orderid) BUCKETS 10;
```

Index

Indexes can facilitate quick filtering and searching of data. Currently, Doris supports two types of indexes:

1. Built-in smart indexes, including prefix index and ZoneMap index.
2. User-created secondary indexes, including inverted index, BloomFilter index, Ngram BloomFilter index, and Bitmap index.

Prefix index

Prefix indexes are built-in indexes in the Aggregate, Unique, and Duplicate data models. The underlying data storage is sorted and stored based on the columns specified as the AGGREGATE KEY, UNIQUE KEY, or DUPLICATE KEY in their respective table creation statements. Prefix index, built on top of the sorted data, allows for quick data querying based on given prefix columns.

Prefix indexes are sparse indexes and cannot locate the exact row where a key is present. Instead, they can only roughly identify the range where the key may exist, and then use binary search algorithms to accurately locate the position of the key.

****Recommendations****

1. When creating a table, **the correct column order can greatly improve query efficiency.**

1. Since the column order is specified during table creation, a table can only have one type of prefix index. However, this may not be efficient enough for queries based on the columns without prefix index. In such cases, users can adjust the column order by creating materialized views.
2. The first field in a prefix index should always be the field of the longest query conditions and should be a high-cardinality field.
 1. Bucketing field: It should have relatively even data distribution and be frequently used, preferably a high-cardinality field.
 2. Int(4) + Int(4) + varchar(50): The prefix index length is only 28.
 3. Int(4) + varchar(50) + Int(4): The prefix index length is only 24.
 4. varchar(10) + varchar(50): The prefix index length is only 30.
 5. Prefix index (36 characters): The first field delivers the best query performance. If a varchar field is encountered, the prefix index will automatically truncate it to the first 20 characters.
 6. If possible, include the most frequently used query fields in the prefix index. Otherwise, specify them as the bucketing fields.
3. The field lengths in the prefix index should be as explicit as possible because Doris can only utilize the prefix index for the first 36 bytes.
4. If it is difficult to design a partitioning, bucketing, and prefix index strategy for your data range, consider introducing inverted indexes for acceleration.

ZoneMap index

ZoneMap index is index information automatically maintained on a per-column basis in the columnar storage format. It includes information such as Min/Max values and the number of Null values. During data querying, the ZoneMap index is utilized to select the data range to scan based on the filtered fields using range conditions.

For example, when filtering the “age” field with the following query statement:

```
SELECT * FROM table WHERE age > 0 and age < 51;
```

If the Short Key Index is not hit, the ZoneMap index will be used to determine the data range, known as the “ordinary” range, that needs to be scanned based on the query conditions for the “age” field. This reduces the number of pages that need to be scanned.

Inverted index

Doris supports inverted indexes since version 2.0.0. Inverted index can be used for full-text searches on text data and range queries on regular numeric and date types. It enables fast filtering of rows that meet the conditions from massive amounts of data.

Best practice

```
-- Inverted index can be specified during table creation or added later. This is an example of specifying it during table creation:  
CREATE TABLE table_name  
(
```

```

columns_definition,
INDEX idx_name1(column_name1) USING INVERTED [PROPERTIES("parser" = "english|unicode|chinese")] [COMMENT
'your comment']
INDEX idx_name2(column_name2) USING INVERTED [PROPERTIES("parser" = "english|unicode|chinese")] [COMMENT
'your comment']
INDEX idx_name3(column_name3) USING INVERTED [PROPERTIES("parser" = "chinese", "parser_mode" =
"fine_grained|coarse_grained")] [COMMENT 'your comment']
INDEX idx_name4(column_name4) USING INVERTED [PROPERTIES("parser" = "english|unicode|chinese",
"support_phrase" = "true|false")] [COMMENT 'your comment']
INDEX idx_name5(column_name4) USING INVERTED [PROPERTIES("char_filter_type" = "char_replace",
"char_filter_pattern" = ". _"), "char_filter_replacement" = " "] [COMMENT 'your comment']
INDEX idx_name5(column_name4) USING INVERTED [PROPERTIES("char_filter_type" = "char_replace",
"char_filter_pattern" = ". _")] [COMMENT 'your comment']
)
table_properties;

-- Example: keyword matching in full-text searches, implemented by MATCH_ANY MATCH_ALL
SELECT * FROM table_name WHERE column_name MATCH_ANY | MATCH_ALL 'keyword1 ...';

```

****Recommendations****

1. If it is difficult to design a partitioning, bucketing, and prefix index strategy for your data range, consider introducing inverted indexes for acceleration.

****Restrictions****

1. Different data models have different restrictions on inverted index.
 1. Aggregate KEY model: only allows inverted index for Key columns
 2. Unique KEY model: allows inverted index for any column after enabling Merge-on-Write
 3. Duplicate KEY model: allows inverted index for any column

BloomFilter index

Doris supports adding BloomFilter indexes to fields with high value distinctiveness, making it suitable for scenarios that involve equivalence queries on columns with high cardinality.

Best practice

```

-- Example: add "bloom_filter_columns"="k1,k2,k3" in the PROPERTIES of the table creation statement.
-- To create BloomFilter index for saler_id and category_id in the table.
CREATE TABLE IF NOT EXISTS sale_detail_bloom (
  sale_date date NOT NULL COMMENT "Sale data",
  customer_id int NOT NULL COMMENT "Customer ID",
  saler_id int NOT NULL COMMENT "Saler ID",
  sku_id int NOT NULL COMMENT "SKU ID",
  category_id int NOT NULL COMMENT "Category ID",
  sale_count int NOT NULL COMMENT "Sale count",
  sale_price DECIMAL(12,2) NOT NULL COMMENT "Sale price",
  sale_amt DECIMAL(20,2) COMMENT "Sale amount"
)
Duplicate KEY(sale_date, customer_id,saler_id,sku_id,category_id)
DISTRIBUTED BY HASH(saler_id) BUCKETS 10
PROPERTIES (

```

```
"bloom_filter_columns"="saler_id,category_id"
);
```

****Restrictions****

1. BloomFilter indexes are not supported for columns of type Tinyint, Float, and Double.
2. BloomFilter indexes can only accelerate filtering using “in” and “=” operators.
3. BloomFilter indexes must be built on high-cardinality columns (above 5000) in query conditions that involve “in” or “=” operators.
 1. BloomFilter indexes are suitable for non-prefix filtering.
 2. Queries will filter based on the high-frequency values in the column, and the filtering conditions are mostly “in” and “=”.
 3. Unlike Bitmap indexes, BloomFilter indexes are suitable for high-cardinality columns, such as UserID. If created on low-cardinality columns like “gender”, each block will contain almost all values, rendering the BloomFilter index meaningless.
 4. It is suitable for cases with data cardinality around half of the total range.
 5. For high-cardinality columns with equality (=) queries, such as ID numbers, using BloomFilter indexes can greatly accelerate performance.

Ngram BloomFilter index

Since 2.0.0, Doris has introduced the NGram BloomFilter index to improve the performance of “**LIKE**” queries.

Best practice

```
-- Example of creating NGram BloomFilter index in table creation statement
CREATE TABLE `nb_table` (
  `siteid` int(11) NULL DEFAULT "10" COMMENT "",
  `citycode` smallint(6) NULL COMMENT "",
  `username` varchar(32) NULL DEFAULT "" COMMENT "",
  INDEX idx_ngrambf (`username`) USING NGRAM_BF PROPERTIES("gram_size"="3", "bf_size"="256") COMMENT
'username ngram_bf index'
) ENGINE=OLAP
AGGREGATE KEY(`siteid`, `citycode`, `username`) COMMENT "OLAP"
DISTRIBUTED BY HASH(`siteid`) BUCKETS 10;

-- PROPERTIES("gram_size"="3", "bf_size"="256"), representing the number of grams and the byte size of the
BloomFilter
-- The number of grams is determined according to the query cases and is typically set to the length of the
majority of query strings. The number of bytes in the BloomFilter can be determined after testing. Generally,
a larger number of bytes leads to better filtering results, and it is recommended to start with a value of
256 for testing and evaluating the effectiveness. However, it's important to note that a larger number of
bytes also increases the storage cost of the index.
-- With high data cardinality, there is no need to set a large BloomFilter size. Conversely, with low data
cardinality, increase the BloomFilter size to enhance filtering efficiency.
```

****Restrictions****

1. NGram BloomFilter index only supports string columns.

2. NGram BloomFilter indexes and BloomFilter indexes are mutually exclusive, meaning that only one of them can be set for the same column.
3. The sizes of the NGram and the BloomFilter can both be optimized based on the actual situation. If the NGram size is relatively small, you may increase the BloomFilter size.
4. For data at the scale of billions or above, if there is a need for fuzzy matching, it is recommended to use inverted indexes or NGram BloomFilter.

Bitmap index

To accelerate data queries, Doris supports users in adding Bitmap indexes to certain fields. This is suitable for scenarios involving equivalence or range queries on columns with lower cardinality.

Best practice

```
-- Example: create Bitmap index for siteid on bitmap_table
CREATE INDEX [IF NOT EXISTS] bitmap_index_name ON
bitmap_table (siteid)
USING BITMAP COMMENT 'bitmap_siteid';
```

****Restrictions****

1. Bitmap indexes can only be created on a single column.
2. Bitmap indexes can be applied to all columns in the Duplicate and Unique Key models, as well as the key columns in the Aggregate Key model.
3. Bitmap indexes support the following data types:
 1. TINYINT
 2. SMALLINT
 3. INT
 4. BIGINT
 5. CHAR
 6. VARCHAR
 7. DATE
 8. DATETIME
 9. LARGEINT
 10. DECIMAL
 11. BOOL
4. Bitmap indexes only take effect under Segment V2. The storage format of tables with Bitmap indexes will be automatically converted to V2 format by default.
5. Bitmap indexes should be constructed within a certain cardinality range. It is not suitable for extremely high or low cardinality cases.
 1. It is recommended for columns with a cardinality between 100 and 100,000, such as the occupation field or city field. If the duplication rate is too high, there won't be significant advantages to build Bitmap indexes compared to other types of indexes. If the duplication rate is too low, Bitmap indexes can significantly reduce space efficiency and performance. Specific types of queries, such as count, OR, and AND operations, only require bitwise operations.

2. Bitmap indexes are more suitable for orthogonal queries.

Field type

Doris supports various field types, including precise deduplication with BITMAP, fuzzy deduplication with HLL, semi-structured data types such as ARRAY/MAP/JSON, as well as common numeric, string, and time types.

****Recommendations****

1. VARCHAR

1. Variable-length string with a length range of 1-65533 bytes. It is stored in UTF-8 encoding, where English characters typically occupy 1 byte.
2. There is often a misunderstanding about the performance difference between varchar(255) and varchar(65533). If the data stored in both cases is the same, the performance will be the same as well. When creating a table, if you are unsure about the maximum length of the field, it is recommended to use varchar(65533) to prevent import errors caused by excessively long strings.

2. STRING

1. Variable-length string with a default size of 1048576 bytes (1MB), which can be increased to 2147483643 bytes (2GB). It is stored in UTF-8 encoding, where English characters typically occupy 1 byte.
2. It can only be used in value columns but not key columns or partitioning columns.
3. It is suitable for storing large text content. However, if such a requirement does not exist, it is recommended to use VARCHAR. STRING columns have limitations as they cannot be used in key columns or partitioning columns.

3. Numeric fields: Choose the appropriate data type based on the required precision. There is no special restrictions on this.

4. Time fields: Note that if there is a high precision requirement (timestamp accurate to milliseconds), you need to specify the use of datetime(6). Otherwise, such timestamps are not supported by default.

5. It is recommended to use the JSON data type instead of string type for storing JSON data.

Create table

create-table-example

Considerations in creating a table include the setting of data partitions and buckets in addition to data model, index, and field types.

Best practice

```
-- Take Merge-on-Write tables in the Unique Key model as an example:  
-- Merge-on-Write in the Unique Key model is implemented in a different way from the Aggregate Key model. The  
performance of it is similar to that on the Duplicate Key model.  
-- In use cases requiring primary key constraints, the Aggregate Key model can deliver much better query  
performance compared to the Duplicate Key model, especially in aggregate queries and queries that involve  
filtering a large amount of data using indexes.  
  
-- For non-partitioned tables  
CREATE TABLE IF NOT EXISTS tbl_unique_merge_on_write  
(  
  `user_id` LARGEINT NOT NULL COMMENT "Use ID",  
  `username` VARCHAR(50) NOT NULL COMMENT "Username",  
  `register_time` DATE COMMENT "User registration time",  
  `city` VARCHAR(20) COMMENT "User city",  
  `age` SMALLINT COMMENT "User age",  
  `sex` TINYINT COMMENT "User gender",  
  `phone` LARGEINT COMMENT "User phone number",  
  `address` VARCHAR(500) COMMENT "User address"  
)  
UNIQUE KEY(`user_id`, `username`)  
-- Data volume of 3~5G  
DISTRIBUTED BY HASH(`user_id`) BUCKETS 10  
PROPERTIES (  
  -- In Doris 1.2.0, as a new feature, Merge-on-Write is disabled by default. Users can enable it by adding the  
following property.  
  "enable_unique_key_merge_on_write" = "true"  
)  
;  
  
-- For partitioned tables
```

```

CREATE TABLE IF NOT EXISTS tbl_unique_merge_on_write_p
(
  `user_id` LARGEINT NOT NULL COMMENT "Use ID",
  `username` VARCHAR(50) NOT NULL COMMENT "Username",
  `register_time` DATE COMMENT "User registration time",
  `city` VARCHAR(20) COMMENT "User city",
  `age` SMALLINT COMMENT "User age",
  `sex` TINYINT COMMENT "User gender",
  `phone` LARGEINT COMMENT "User phone number",
  `address` VARCHAR(500) COMMENT "User address"
)
UNIQUE KEY(`user_id`, `username`, `register_time`)
PARTITION BY RANGE(`register_time`) (
  PARTITION p00010101_1899 VALUES [('0001-01-01'), ('1900-01-01')),
  PARTITION p19000101 VALUES [('1900-01-01'), ('1900-01-02')),
  PARTITION p19000102 VALUES [('1900-01-02'), ('1900-01-03')),
  PARTITION p19000103 VALUES [('1900-01-03'), ('1900-01-04')),
  PARTITION p19000104_1999 VALUES [('1900-01-04'), ('2000-01-01')),
  FROM ("2000-01-01") TO ("2022-01-01") INTERVAL 1 YEAR,
  PARTITION p30001231 VALUES [('3000-12-31'), ('3001-01-01')),
  PARTITION p99991231 VALUES [('9999-12-31'), (MAXVALUE))
)
-- Data volume of 3~5G
DISTRIBUTED BY HASH(`user_id`) BUCKETS 10
PROPERTIES (
  -- In Doris 1.2.0, as a new feature, Merge-on-Write is disabled by default. Users can enable it by adding the
  following property.
  "enable_unique_key_merge_on_write" = "true",
  -- The unit for dynamic partition scheduling can be specified as HOUR, DAY, WEEK, MONTH, or YEAR.
  "dynamic_partition.time_unit" = "MONTH",
  -- The starting offset for dynamic partitioning is specified as a negative number. Depending on the value of
  the time_unit, it uses the current day (week/month) as the reference point, partitions prior to this offset
  will be deleted (TTL). If not specified, the default value is -2147483648, indicating that historical
  partitions will not be deleted.
  "dynamic_partition.start" = "-3000",
  -- The ending offset for dynamic partitioning is specified as a positive number. Depending on the value of
  the time_unit, it uses the current day (week/month) as the reference point. Create the corresponding
  partitions of the specified range in advance.
  "dynamic_partition.end" = "10",
  -- The prefix for names of the dynamically created partitions (required).
  "dynamic_partition.prefix" = "p",
  -- The number of buckets corresponding to the dynamically created partitions.
  "dynamic_partition.buckets" = "10",
  "dynamic_partition.enable" = "true",
  -- The following is the number of replicas corresponding to dynamically created partitions. If not specified,
  the default value will be the replication factor specified when creating the table, which is typically 3.
  "dynamic_partition.replication_num" = "3",
  "replication_num" = "3"
);

-- View existing partitions
-- The actual number of created partitions is determined by a combination of dynamic_partition.start,
dynamic_partition.end, and the settings of PARTITION BY RANGE.
show partitions from tbl_unique_merge_on_write_p;

```

****Restrictions****

1. The database character set should be specified as UTF-8 since only UTF-8 is supported.
2. The replication factor for tables must be 3 (if not specified, it defaults to 3).

3. The data volume of an individual tablet (**Tablet Count = Partition Count * Bucket Count * Replication Factor**) theoretically has no upper or lower bounds, except for small tables (in the range of hundreds of megabytes to one gigabyte), where it should be ensured to be within the range of 1 GB to 10 GB:

1. If the data volume of an individual tablet is too small, it can result in poor data aggregation performance and increased metadata management overhead.
2. If the data volume is too large, it hinders replica migration, synchronization, and increases the cost of schema changes or materialization operations (these operations are retried at the granularity of a tablet).

4. For data exceeding 500 million records, **partitioning and bucketing** strategies must be implemented:

1. Recommendations for bucketing:

1. For large tables, each tablet should be in the range of 1 GB to 10 GB to prevent the generation of too many small files.
2. For dimension tables of approximately 100 megabytes, the number of tablets should be controlled within the range of 3 to 5. This ensures a certain level of concurrency without generating excessive small files.
2. If partitioning is not feasible and the data grows rapidly without the possibility of dynamic time-based partitioning, it is advisable to increase the number of buckets to accommodate the data volume based on the data retention period (180 days). It is still recommended to keep the size of each bucket between 1 GB and 10 GB.
3. Apply salting to the bucketing field and use the same salting strategy for queries in order to leverage bucket pruning capabilities.
4. Random bucketing:
 1. If an OLAP table does not have fields that need to be updated, setting the data bucketing mode to RANDOM can avoid severe data skew. During data ingestion, each batch of data is randomly assigned to a tablet for writing.
 2. When the bucketing mode for a table is set to RANDOM, since there is no bucketing column, querying the table will scan all buckets in the hit partitions instead of querying specific buckets based on the values of the bucketing column. This setting is suitable for overall aggregation and analysis queries rather than high-concurrency point queries.
 3. If an OLAP table has a random distribution of data, setting the `load_to_single_tablet` parameter to true during data ingestion allows each task to write to a single tablet. This improves concurrency and throughput during large-scale data ingestion. It can also reduce the write amplification caused by data ingestion and compaction and ensure cluster stability.
5. Dimension tables, which grow slowly, can use a single partition and apply bucketing based on commonly used query conditions (where the data distribution of the bucketing field is relatively even).
6. Fact tables: We recommend using DATE or DATETIME as the partitioning column. In most cases, one partition per day is sufficient. For the bucketing strategy, use frequently queried columns with relatively even data distribution as the bucketing columns.

5. For scenarios where there is a large amount of historical partitioned data but the historical data is relatively small, unbalanced, or queried infrequently, you can use the following approach to place the data in special partitions. You can create historical partitions for historical data of small sizes (e.g., yearly partitions, monthly partitions). For example, you can create historical partitions for data FROM ("2000-01-01") TO ("2022-01-01") INTERVAL 1 YEAR:

```
PARTITION p00010101_1899 VALUES [('0001-01-01'), ('1900-01-01')),  
PARTITION p19000101 VALUES [('1900-01-01'), ('1900-01-02')),  
...  
PARTITION p19000104_1999 VALUES [('1900-01-04'), ('2000-01-01')),  
FROM ("2000-01-01") TO ("2022-01-01") INTERVAL 1 YEAR,  
PARTITION p30001231 VALUES [('3000-12-31'), ('3001-01-01')),  
PARTITION p99991231 VALUES [('9999-12-31'), (MAXVALUE)]
```

Loading Overview

Apache Doris offers various methods for importing and integrating data, allowing you to import data from various sources into the database. These methods can be categorized into four types:

- **Real-Time Writing:** Data is written into Doris tables in real-time via HTTP or JDBC, suitable for scenarios requiring immediate analysis and querying.
 - For small amounts of data (once every 5 minutes), you can use [JDBC INSERT](#).
 - For higher concurrency or frequency (more than 20 concurrent writes or multiple writes per minute), you can enable [Group Commit](#) and use JDBC INSERT or Stream Load.
 - For high throughput, you can use [Stream Load](#) via HTTP.
- **Streaming Synchronization:** Real-time data streams (e.g., Flink, Kafka, transactional databases) are imported into Doris tables, ideal for real-time analysis and querying.
 - You can use [Flink Doris Connector](#) to write Flink's real-time data streams into Doris.
 - You can use [Routine Load](#) or [Doris Kafka Connector](#) for Kafka's real-time data streams. Routine Load pulls data from Kafka to Doris and supports CSV and JSON formats, while Kafka Connector writes data to Doris, supporting Avro, JSON, CSV, and Protobuf formats.
 - You can use [Flink CDC](#) or [Datax](#) to write transactional database CDC data streams into Doris.
- **Batch Import:** Data is batch-loaded from external storage systems (e.g., Object Storage, HDFS, local files, NAS) into Doris tables, suitable for non-real-time data import needs.
 - You can use [Broker Load](#) to write files from Object Storage and HDFS into Doris.
 - You can use [INSERT INTO SELECT](#) to synchronously load files from Object Storage, HDFS, and NAS into Doris, and you can perform the operation asynchronously using a [JOB](#).
 - You can use [Stream Load](#) or [Doris Streamloader](#) to write local files into Doris.
- **External Data Source Integration:** Query and partially import data from external sources (e.g., Hive, JDBC, Iceberg) into Doris tables.
 - You can create a [Catalog](#) to read data from external sources and use [INSERT INTO SELECT](#) to synchronize this data into Doris, with asynchronous execution via [JOB](#).

Each import method in Doris is an implicit transaction by default. For more information on transactions, refer to [Transactions](#).

Quick Overview of Import Methods

Doris import process mainly involves various aspects such as data sources, data formats, import methods, error handling, data transformation, and transactions. You can quickly browse the scenarios suitable for each import method and the supported file formats in the table below.

Import Method	Use Case	Supported File Formats	Import Mode
Stream Load	Importing local files or push data in applications via HTTP.	csv, json, parquet, orc	Synchronous
Broker Load	Importing from object storage, HDFS, etc.	csv, json, parquet, orc	Asynchronous
INSERT INTO VALUES	Writing data via JDBC.	SQL	Synchronous
INSERT INTO SELECT	Importing from an external source like a table in a catalog or files in Object Storage, HDFS.	SQL	Synchronous, Asynchronous via Job
Routine Load	Real-time import from Kafka	csv, json	Asynchronous
MySQL Load	Importing from local files.	csv	Synchronous
Group Commit	Writing with high frequency.	Depending on the import method used	-

local file

Doris provides multiple ways to load data from local sources:

1. Stream Load

Load local files or data streams into Doris via HTTP protocol. Supports CSV, JSON, Parquet, and ORC formats. For more information, refer to the [Stream Load documentation](#).

2. Streamloader Tool

The Streamloader tool is a dedicated client tool for loading data into the Doris database, based on Stream Load. It can provide multi-file and concurrent load capabilities, reducing the time required for loading large volumes of data. For more documentation, refer to [Streamloader](#).

3. MySQL Load

Doris is compatible with MySQL protocol and supports using the standard [LOAD DATA](#) syntax to load local files, suitable for loading CSV files.

Using Stream Load to Load Data

Step 1: Prepare Data

Create a CSV file named `streamload_example.csv` with the following content:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create Table

Create a table in Doris with the following syntax:

```
CREATE TABLE testdb.test_streamload(
  user_id BIGINT NOT NULL COMMENT "User ID",
  name VARCHAR(20) COMMENT "User Name",
  age INT COMMENT "User Age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load Data

Submit a Stream Load job using curl:

```
curl --location-trusted -u <doris_user>:<doris_password> \  
-H "column_separator:," \  
-H "columns:user_id,name,age" \  
-T streamload_example.csv \  
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

Example of load result:

```
{  
  "TxnId": 3,  
  "Status": "Success",  
  "NumberTotalRows": 10,  
  "NumberLoadedRows": 10  
}
```

Step 4: Check Loaded Data

```
mysql> SELECT COUNT(*) FROM testdb.test_streamload;  
+-----+  
| count(*) |  
+-----+  
|      10 |  
+-----+
```

Using Streamloader Tool to Load Data

Step 1: Prepare Data

Create a CSV file named `streamloader_example.csv` with the same content as above.

Step 2: Create Table

Create the table in Doris with the same syntax as above.

Step 3: Load Data

Use the Streamloader tool to load data:

```
doris-streamloader --source_file="streamloader_example.csv" --url="http://localhost:8330" --  
header="column_separator:," --db="testdb" --table="test_streamload"
```

Example of load result:

```
Load Result: {  
  "Status": "Success",  
  "TotalRows": 10,  
}
```

```
"LoadedRows": 10
}
```

Step 4: Check Loaded Data

```
mysql> SELECT COUNT(*) FROM testdb.test_streamload;
+-----+
| count(*) |
+-----+
|        10 |
+-----+
```

Using MySQL Load to Load Data

Step 1: Prepare Data

Create a file named `client_local.csv` with the following sample data:

```
1,10
2,20
3,30
4,40
5,50
6,60
```

Step 2: Connect to MySQL Client

```
mysql --local-infile -h <fe_ip> -P <fe_query_port> -u root -D testdb
```

Step 3: Load Data

Execute the MySQL Load command:

```
LOAD DATA LOCAL
INFILE 'client_local.csv'
INTO TABLE testdb.t1
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n';
```

Step 4: Check Loaded Data

If the load is successful, the result will be displayed as follows:

```
Query OK, 6 rows affected (0.17 sec)
Records: 6  Deleted: 0  Skipped: 0  Warnings: 0
```

Kafka

Doris provides the following methods to load data from Kafka:

- **Using Routine Load to consume Kafka data**

Doris continuously consumes data from Kafka Topics through Routine Load. After submitting a Routine Load job, Doris generates load tasks in real-time to consume messages from the specified Topic in the Kafka cluster. Routine Load supports CSV and JSON formats, with Exactly-Once semantics, ensuring that data is neither lost nor duplicated. For more documentation, please refer to [Routine Load](#).

- **Doris Kafka Connector to consume Kafka data**

The Doris Kafka Connector is a tool for loading Kafka data streams into the Doris database. Users can easily load various serialization formats (such as JSON, Avro, Protobuf) through the Kafka Connect plugin, and it supports parsing data formats from the Debezium component. For more documentation, please refer to [Doris Kafka Connector](#).

In most cases, you can directly choose Routine Load for loading data without the need to integrate external components to consume Kafka data. When you need to load data in Avro or Protobuf formats, or data collected from upstream databases via Debezium, you can use the Doris Kafka Connector.

Using Routine Load to consume Kafka data

Usage Restrictions

1. Supported message formats are CSV and JSON. Each CSV message is one line, and the line does not contain a newline character at the end;
2. By default, it supports Kafka version 0.10.0.0 and above. If you need to use older versions (such as 0.9.0, 0.8.2, 0.8.1, 0.8.0), you need to modify the BE configuration to set `kafka_broker_version_fallback` to a compatible older version, or set `property.broker.version.fallback` when creating the Routine Load. Using older versions may result in some new features being unavailable, such as setting Kafka partition offsets based on time.

Operation Example

In Doris, create a persistent Routine Load load task through the `CREATE ROUTINE LOAD` command, which can be divided into single-table load and multi-table load. For detailed syntax, please refer to [CREATE ROUTINE LOAD](#).

Single Table Load

Step 1: Prepare Data

In Kafka, sample data is as follows:

```
kafka-console-consumer.sh --bootstrap-server localhost:9092 --topic test-routine-load-csv --from-beginning 1,Emily,25
```

Step 2: Create Table in Database

Create the table to be loaded in Doris, with the following syntax:

```
CREATE TABLE testdb.test_routineload_tbl(  
  user_id          BIGINT          NOT NULL COMMENT "user id",  
  name             VARCHAR(20)      COMMENT "name",  
  age              INT              COMMENT "age"  
)  
DUPLICATE KEY(user_id)  
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Create Routine Load job to load data into a single table

In Doris, use the CREATE ROUTINE LOAD command to create the load job:

```
CREATE ROUTINE LOAD testdb.example_routine_load_csv ON test_routineload_tbl  
COLUMNS TERMINATED BY ",",  
COLUMNS(user_id, name, age)  
FROM KAFKA(  
  "kafka_broker_list" = "192.168.88.62:9092",  
  "kafka_topic" = "test-routine-load-csv",  
  "property.kafka_default_offsets" = "OFFSET_BEGINNING"  
);
```

Step 4: Check Loaded Data

```
select * from test_routineload_tbl;  
+-----+-----+-----+  
| user_id | name   | age |  
+-----+-----+-----+  
| 1       | Emily  | 25  |  
+-----+-----+-----+
```

Multi-Table Load

In scenarios where multiple tables need to be loaded simultaneously, the data in Kafka must include table name information, formatted as: table_name|data. For example, when loading CSV data, the format should be: table_name|val1,val2,val3. Please note that the table name must exactly match the table name in Doris; otherwise, the loading will fail, and the column_mapping configuration introduced later is not supported.

Step 1: Prepare Data

In Kafka, sample data is as follows:

```
kafka-console-consumer.sh --bootstrap-server localhost:9092 --topic test-multi-table-load --from-beginning  
test_multi_table_load1|1,Emily,25  
test_multi_table_load2|2,Benjamin,35
```

Step 2: Create Tables in Database

Create the tables to be loaded in Doris, with the following syntax:

Table 1:

```
CREATE TABLE test_multi_table_load1(
  user_id      BIGINT      NOT NULL COMMENT "User ID",
  name         VARCHAR(20) COMMENT "User Name",
  age          INT         COMMENT "User Age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Table 2:

```
CREATE TABLE test_multi_table_load2(
  user_id      BIGINT      NOT NULL COMMENT "User ID",
  name         VARCHAR(20) COMMENT "User Name",
  age          INT         COMMENT "User Age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Create Routine Load job to load data into multiple tables

In Doris, use the CREATE ROUTINE LOAD command to create the load job:

```
CREATE ROUTINE LOAD example_multi_table_load
COLUMNS TERMINATED BY ","
FROM KAFKA(
  "kafka_broker_list" = "192.168.88.62:9092",
  "kafka_topic" = "test-multi-table-load",
  "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

Step 4: Check Loaded Data

```
select * from test_multi_table_load1;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 1       | Emily     | 25  |
+-----+-----+-----+

select * from test_multi_table_load2;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 2       | Benjamin  | 35  |
+-----+-----+-----+
```

Configure Security Authentication

For methods of configuring Kafka with authentication, please refer to [Kafka Security Authentication](#).

Using Doris Kafka Connector to consume Kafka data

The Doris Kafka Connector is a tool for loading Kafka data streams into the Doris database. Users can easily load various serialization formats (such as JSON, Avro, Protobuf) through the Kafka Connect plugin, and it supports parsing data formats from the Debezium component.

Start in Distributed Mode

[Distributed](#) mode provides scalability and automatic fault tolerance for Kafka Connect. In this mode, multiple worker processes can be started using the same `group.id`, which will coordinate the execution of connectors and tasks across all available worker processes.

1. Create a plugins directory under `$KAFKA_HOME` and place the downloaded `doris-kafka-connector` jar package inside.
2. Configure `config/connect-distributed.properties`:

```
# Modify kafka server address
bootstrap.servers=127.0.0.1:9092

# Modify group.id, which needs to be consistent across the same cluster
group.id=connect-cluster

# Modify to the created plugins directory
# Note: Please fill in the direct path of Kafka here. For example: plugin.path=/opt/kafka/plugins
plugin.path=$KAFKA_HOME/plugins

# It is recommended to increase Kafka's max.poll.interval.ms time to over 30 minutes, default is 5 minutes
# To avoid Stream Load data load consumption timeout, causing the consumer to be kicked out of the
consumption group
max.poll.interval.ms=1800000
consumer.max.poll.interval.ms=1800000
```

3. Start:

```
$KAFKA_HOME/bin/connect-distributed.sh -daemon $KAFKA_HOME/config/connect-distributed.properties
```

4. Consume Kafka data:

```
curl -i http://127.0.0.1:8083/connectors -H "Content-Type: application/json" -X POST -d '{
  "name":"test-doris-sink-cluster",
  "config":{
    "connector.class":"org.apache.doris.kafka.connector.DorisSinkConnector",
    "topics":"topic_test",
    "doris.topic2table.map": "topic_test:test_kafka_tbl",
    "buffer.count.records":"10000",
    "buffer.flush.time":"120",
    "buffer.size.bytes":"5000000",
    "doris.urls":"10.10.10.1",
    "doris.user":"root",
    "doris.password":"",
    "doris.http.port":"8030",
    "doris.query.port":"9030",
    "doris.database":"test_db",
    "key.converter":"org.apache.kafka.connect.storage.StringConverter",
    "value.converter":"org.apache.kafka.connect.storage.StringConverter"
```

```
}  
}'
```

Operate Kafka Connect

```
# View connector status  
curl -i http://127.0.0.1:8083/connectors/test-doris-sink-cluster/status -X GET  
# Delete current connector  
curl -i http://127.0.0.1:8083/connectors/test-doris-sink-cluster -X DELETE  
# Pause current connector  
curl -i http://127.0.0.1:8083/connectors/test-doris-sink-cluster/pause -X PUT  
# Resume current connector  
curl -i http://127.0.0.1:8083/connectors/test-doris-sink-cluster/resume -X PUT  
# Restart tasks within the connector  
curl -i http://127.0.0.1:8083/connectors/test-doris-sink-cluster/tasks/0/restart -X POST
```

For an introduction to Distributed mode, please refer to [Distributed Workers](#).

Load Ordinary Data

1. Load sample data:

In Kafka, sample data is as follows:

```
kafka-console-consumer.sh --bootstrap-server localhost:9092 --topic test-data-topic --from-beginning  
{ "user_id":1,"name":"Emily","age":25}  
{ "user_id":2,"name":"Benjamin","age":35}  
{ "user_id":3,"name":"Olivia","age":28}  
{ "user_id":4,"name":"Alexander","age":60}  
{ "user_id":5,"name":"Ava","age":17}  
{ "user_id":6,"name":"William","age":69}  
{ "user_id":7,"name":"Sophia","age":32}  
{ "user_id":8,"name":"James","age":64}  
{ "user_id":9,"name":"Emma","age":37}  
{ "user_id":10,"name":"Liam","age":64}
```

2. Create the table to be loaded:

Create the table to be loaded in Doris, with the following syntax:

```
CREATE TABLE test_db.test_kafka_connector_tbl(  
  user_id          BIGINT      NOT NULL COMMENT "user id",  
  name             VARCHAR(20) COMMENT "name",  
  age              INT         COMMENT "age"  
)  
DUPLICATE KEY(user_id)  
DISTRIBUTED BY HASH(user_id) BUCKETS 12;
```

3. Create the load task:

On the machine where Kafka Connect is deployed, submit the following load task via curl command:

```
curl -i http://127.0.0.1:8083/connectors -H "Content-Type: application/json" -X POST -d '{  
  "name":"test-doris-sink-cluster",  
  "config":{  
    "connector.class":"org.apache.doris.kafka.connector.DorisSinkConnector",
```

```

    "tasks.max":"10",
    "topics":"test-data-topic",
    "doris.topic2table.map": "test-data-topic:test_kafka_connector_tbl",
    "buffer.count.records":"10000",
    "buffer.flush.time":"120",
    "buffer.size.bytes":"5000000",
    "doris.urls":"10.10.10.1",
    "doris.user":"root",
    "doris.password":"",
    "doris.http.port":"8030",
    "doris.query.port":"9030",
    "doris.database":"test_db",
    "key.converter":"org.apache.kafka.connect.storage.StringConverter",
    "value.converter":"org.apache.kafka.connect.storage.StringConverter"
  }
}'

```

Load Data Collected by Debezium Component

1. The MySQL database has the following table:

```

CREATE TABLE test.test_user (
  user_id int NOT NULL ,
  name varchar(20),
  age int,
  PRIMARY KEY (user_id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci;

insert into test.test_user values(1,'zhangsan',20);
insert into test.test_user values(2,'lisi',21);
insert into test.test_user values(3,'wangwu',22);

```

2. Create the table to be loaded in Doris:

```

CREATE TABLE test_db.test_user(
  user_id          BIGINT          NOT NULL COMMENT "user id",
  name             VARCHAR(20)      COMMENT "name",
  age              INT              COMMENT "age"
)
UNIQUE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 12;

```

3. Deploy the Debezium connector for MySQL component, refer to: [Debezium connector for MySQL](#).

4. Create the doris-kafka-connector load task:

Assuming the data from the MySQL table collected by Debezium is in the `mysql_debezium.test.test_user` Topic:

```

curl -i http://127.0.0.1:8083/connectors -H "Content-Type: application/json" -X POST -d '{
  "name":"test-debezium-doris-sink",
  "config":{
    "connector.class":"org.apache.doris.kafka.connector.DorisSinkConnector",
    "tasks.max":"10",
    "topics":"mysql_debezium.test.test_user",
    "doris.topic2table.map": "mysql_debezium.test.test_user:test_user",
    "buffer.count.records":"10000",
    "buffer.flush.time":"120",

```

```

    "buffer.size.bytes":"5000000",
    "doris.urls":"10.10.10.1",
    "doris.user":"root",
    "doris.password":"",
    "doris.http.port":"8030",
    "doris.query.port":"9030",
    "doris.database":"test_db",
    "converter.mode":"debezium_ingestion",
    "enable.delete":"true",
    "key.converter":"org.apache.kafka.connect.json.JsonConverter",
    "value.converter":"org.apache.kafka.connect.json.JsonConverter"
  }
}'

```

Load Data in AVRO Serialization Format

```

curl -i http://127.0.0.1:8083/connectors -H "Content-Type: application/json" -X POST -d '{
  "name":"doris-avro-test",
  "config":{
    "connector.class":"org.apache.doris.kafka.connector.DorisSinkConnector",
    "topics":"avro_topic",
    "tasks.max":"10",
    "doris.topic2table.map": "avro_topic:avro_tab",
    "buffer.count.records":"100000",
    "buffer.flush.time":"120",
    "buffer.size.bytes":"10000000",
    "doris.urls":"10.10.10.1",
    "doris.user":"root",
    "doris.password":"",
    "doris.http.port":"8030",
    "doris.query.port":"9030",
    "doris.database":"test",
    "load.model":"stream_load",
    "key.converter":"io.confluent.connect.avro.AvroConverter",
    "key.converter.schema.registry.url":"http://127.0.0.1:8081",
    "value.converter":"io.confluent.connect.avro.AvroConverter",
    "value.converter.schema.registry.url":"http://127.0.0.1:8081"
  }
}'

```

Load Data in Protobuf Serialization Format

```

curl -i http://127.0.0.1:8083/connectors -H "Content-Type: application/json" -X POST -d '{
  "name":"doris-protobuf-test",
  "config":{
    "connector.class":"org.apache.doris.kafka.connector.DorisSinkConnector",
    "topics":"proto_topic",
    "tasks.max":"10",
    "doris.topic2table.map": "proto_topic:proto_tab",
    "buffer.count.records":"100000",
    "buffer.flush.time":"120",
    "buffer.size.bytes":"10000000",
    "doris.urls":"10.10.10.1",
    "doris.user":"root",
    "doris.password":"",
    "doris.http.port":"8030",
    "doris.query.port":"9030",
    "doris.database":"test",
    "load.model":"stream_load",
    "key.converter":"io.confluent.connect.protobuf.ProtobufConverter",

```

```
"key.converter.schema.registry.url":"http://127.0.0.1:8081",  
"value.converter":"io.confluent.connect.protobuf.ProtobufConverter",  
"value.converter.schema.registry.url":"http://127.0.0.1:8081"  
}  
'
```

Flink

Using the Flink Doris Connector, you can load data generated by Flink (such as data read from Kafka or MySQL) into Doris in real-time.

Limitations

Requires a user-deployed Flink cluster.

Loading Data Using Flink

For detailed steps on loading data using Flink, please refer to [Flink-Doris-Connector](#). The following steps demonstrate how to quickly load data using Flink.

Step 1: Create Table

```
CREATE TABLE `students` (  
  `id` INT NULL,  
  `name` VARCHAR(256) NULL,  
  `age` INT NULL  
) ENGINE=OLAP  
UNIQUE KEY(`id`)  
COMMENT 'OLAP'  
DISTRIBUTED BY HASH(`id`) BUCKETS 1  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 1"  
);
```

Step 2: Load Data Using Flink

Run bin/sql-client.sh to open the FlinkSQL console

```
CREATE TABLE student_sink (  
  id INT,  
  name STRING,  
  age INT  
)  
WITH (  
  'connector' = 'doris',  
  'fenodes' = '10.16.10.6:28737',  
  'table.identifier' = 'test.students',  
  'username' = 'root',  
  'password' = '',  
  'sink.label-prefix' = 'doris_label'  
);  
  
INSERT INTO student_sink values(1,'zhangsan',123)
```

Step 3: Verify Loaded Data

```
select * from test.students;  
+-----+-----+-----+  
| id   | name   | age   |  
+-----+-----+-----+  
| 1    | zhangsan | 123   |  
+-----+-----+-----+
```

HDFS | Data Source

HDFS

Doris provides two ways to load files from HDFS: - Use HDFS Load to load HDFS files into Doris, which is an asynchronous load method. - Use TVF to load HDFS files into Doris, which is a synchronous load method.

load with HDFS Load

Use HDFS Load to import files on HDFS. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file hdfsload_example.csv The file is stored on HDFS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_hdfsload(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using HDFS Load

```
LOAD LABEL hdfs_load_2022_04_01
(
  DATA INFILE("hdfs://127.0.0.1:8020/tmp/hdfsload_example.csv")
  INTO TABLE test_hdfsload
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
with HDFS
(
  "fs.defaultFS" = "hdfs://127.0.0.1:8020",
  "hadoop.username" = "user"
```

```
)
PROPERTIES
(
  "timeout" = "3600"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_hdfsload;
```

Results:

```
mysql> select * from test_hdfsload;
+-----+-----+-----+
| user_id | name    | age |
+-----+-----+-----+
| 5       | Ava     | 17  |
| 10      | Liam    | 64  |
| 7       | Sophia  | 32  |
| 9       | Emma    | 37  |
| 1       | Emily   | 25  |
| 4       | Alexander | 60  |
| 2       | Benjamin | 35  |
| 3       | Olivia  | 28  |
| 6       | William | 69  |
| 8       | James   | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Load with TVF

Step 1: Prepare the data

Create a CSV file hdfsload_example.csv The file is stored on HDFS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_hdfsload(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
```

```
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

```
INSERT INTO test_hdfsload
SELECT * FROM hdfs (
  "uri" = "hdfs://127.0.0.1:8020/tmp/hdfsload_example.csv",
  "fs.defaultFS" = "hdfs://127.0.0.1:8020",
  "hadoop.username" = "doris",
  "format" = "csv",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_hdfsload;
```

Results:

```
mysql> select * from test_hdfsload;
+-----+-----+-----+
| user_id | name    | age |
+-----+-----+-----+
| 5       | Ava     | 17  |
| 10      | Liam    | 64  |
| 7       | Sophia  | 32  |
| 9       | Emma    | 37  |
| 1       | Emily   | 25  |
| 4       | Alexander | 60  |
| 2       | Benjamin | 35  |
| 3       | Olivia  | 28  |
| 6       | William | 69  |
| 8       | James   | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Amazon S3

Doris provides two ways to load files from AWS S3: - Use S3 Load to load S3 files into Doris, which is an asynchronous load method. - Use TVF to load S3 files into Doris, which is a synchronous load method.

load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on S3 and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data with S3 Load

```
LOAD LABEL s3_load_2022_04_01
(
  DATA INFILE("s3://your_bucket_name/s3load_example.csv")
  INTO TABLE test_s3load
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
WITH S3
(
  "provider" = "S3",
  "s3.endpoint" = "https://s3.us-west-2.amazonaws.com",
  "s3.region" = "us-west-2",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>"
)
```

```
)  
PROPERTIES  
(  
    "timeout" = "3600"  
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;  
+-----+-----+-----+  
| user_id | name      | age |  
+-----+-----+-----+  
|      5 | Ava      | 17 |  
|     10 | Liam     | 64 |  
|      7 | Sophia   | 32 |  
|      9 | Emma     | 37 |  
|      1 | Emily    | 25 |  
|      4 | Alexander| 60 |  
|      2 | Benjamin | 35 |  
|      3 | Olivia   | 28 |  
|      6 | William  | 69 |  
|      8 | James    | 64 |  
+-----+-----+-----+  
10 rows in set (0.04 sec)
```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on S3 and its content is as follows:

```
1,Emily,25  
2,Benjamin,35  
3,Olivia,28  
4,Alexander,60  
5,Ava,17  
6,William,69  
7,Sophia,32  
8,James,64  
9,Emma,37  
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(  
    user_id      BIGINT      NOT NULL COMMENT "user id",  
    name         VARCHAR(20)  COMMENT "name",  
    age          INT          COMMENT "age"  
);
```

```
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "s3.endpoint" = "https://s3.us-west-2.amazonaws.com",
  "s3.region" = "us-west-2",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 5       | Ava       | 17  |
| 10      | Liam      | 64  |
| 7       | Sophia    | 32  |
| 9       | Emma      | 37  |
| 1       | Emily     | 25  |
| 4       | Alexander | 60  |
| 2       | Benjamin  | 35  |
| 3       | Olivia    | 28  |
| 6       | William   | 69  |
| 8       | James     | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Google Cloud Storage | Data Source

Google Cloud Storage

Doris provides two ways to load files from Google Cloud Storage: - Use S3 Load to load Google Cloud Storage files into Doris, which is an asynchronous load method. - Use TVF to load Google Cloud Storage files into Doris, which is a synchronous load method.

load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Google Cloud Storage and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

```
LOAD LABEL s3_load_2022_04_01
(
  DATA INFILE("s3://your_bucket_name/s3load_example.csv")
  INTO TABLE test_s3load
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
WITH S3
(
  "provider" = "GCP",
```

```

"s3.endpoint" = "storage.us-west2.rep.googleapis.com",
"s3.region" = "US-WEST2",
"s3.access_key" = "<your-ak>",
"s3.secret_key" = "<your-sk>"
)
PROPERTIES
(
    "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```

mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
|      5 | Ava      | 17 |
|     10 | Liam     | 64 |
|      7 | Sophia   | 32 |
|      9 | Emma     | 37 |
|      1 | Emily    | 25 |
|      4 | Alexander| 60 |
|      2 | Benjamin | 35 |
|      3 | Olivia   | 28 |
|      6 | William  | 69 |
|      8 | James    | 64 |
+-----+-----+-----+
10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Google Cloud Storage and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64

```

Step 2: Create a table in Doris

```

CREATE TABLE test_s3load(
    user_id          BIGINT          NOT NULL COMMENT "user id",

```

```

    name          VARCHAR(20)      COMMENT "name",
    age           INT              COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;

```

Step 3: Load data using TVF

```

INSERT INTO test_s3load
SELECT * FROM S3
(
    "uri" = "s3://your_bucket_name/s3load_example.csv",
    "format" = "csv",
    "provider" = "GCP",
    "s3.endpoint" = "storage.us-west2.rep.googleapis.com",
    "s3.region" = "US-WEST2",
    "s3.access_key" = "<your-ak>",
    "s3.secret_key" = "<your-sk>",
    "column_separator" = ",",
    "csv_schema" = "user_id:int;name:string;age:int"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```

mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
| 5 | Ava   | 17 |
| 10 | Liam  | 64 |
| 7 | Sophia | 32 |
| 9 | Emma  | 37 |
| 1 | Emily  | 25 |
| 4 | Alexander | 60 |
| 2 | Benjamin | 35 |
| 3 | Olivia | 28 |
| 6 | William | 69 |
| 8 | James  | 64 |
+-----+-----+-----+
10 rows in set (0.04 sec)

```

Azure Storage

Doris provides two ways to load files from Azure Storage: - Use S3 Load to load Azure Storage files into Doris, which is an asynchronous load method. - Use TVF to load Azure Storage files into Doris, which is a synchronous load method.

load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Azure Storage and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

Caution

When importing data from Azure Storage with S3 Load, note the following:

- Azure Storage requires HTTPS transmission by default (Secure transfer required: Enabled). To access Azure Storage properly, set `s3_client_http_scheme = https` in Doris `be.conf`.
- The `s3.region` setting in Azure S3 properties can be omitted.

```
LOAD LABEL s3_load_2022_04_01
(
```

```

DATA INFILE("s3://your_bucket_name/s3load_example.csv")
INTO TABLE test_s3load
COLUMNS TERMINATED BY ","
FORMAT AS "CSV"
(user_id, name, age)
)
WITH S3
(
  "provider" = "AZURE",
  "s3.endpoint" = "StorageAccountA.blob.core.windows.net",
  "s3.region" = "westus3",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>"
)
PROPERTIES
(
  "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```

mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 5 | Ava      | 17 |
| 10 | Liam     | 64 |
| 7 | Sophia   | 32 |
| 9 | Emma     | 37 |
| 1 | Emily    | 25 |
| 4 | Alexander | 60 |
| 2 | Benjamin | 35 |
| 3 | Olivia   | 28 |
| 6 | William  | 69 |
| 8 | James    | 64 |
+-----+-----+-----+
10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Azure Storage and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64

```

```
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

Caution

When importing data from Azure Storage with TVF, note the following:

- Azure Storage requires HTTPS transmission by default (Secure transfer required: Enabled). To access Azure Storage properly, set `s3_client_http_scheme = https` in Doris `be.conf`.
- The `s3.region` setting in Azure S3 properties can be omitted.

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "AZURE",
  "s3.endpoint" = "StorageAccountA.blob.core.windows.net",
  "s3.region" = "westus3",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
|      5 | Ava    | 17  |
|     10 | Liam   | 64  |
|      7 | Sophia | 32  |
|      9 | Emma   | 37  |
```

	1	Emily	25	
	4	Alexander	60	
	2	Benjamin	35	
	3	Olivia	28	
	6	William	69	
	8	James	64	
+-----+

Alibaba Cloud OSS

Doris provides two ways to load files from Alibaba Cloud OSS: - Use S3 Load to load Alibaba Cloud OSS files into Doris, which is an asynchronous load method. - Use TVF to load Alibaba Cloud OSS files into Doris, which is a synchronous load method.

load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Alibaba Cloud OSS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

Caution

The endpoint URLs for public and internal access are different. If the server and OSS are in the same region, it is recommended to use the internal endpoint link.

- internal endpoint: oss-cn-hangzhou-internal.aliyuncs.com
- public endpoint: oss-cn-hangzhou.aliyuncs.com

```
LOAD LABEL s3_load_2022_04_01
(
```

```

DATA INFILE("s3://your_bucket_name/s3load_example.csv")
INTO TABLE test_s3load
COLUMNS TERMINATED BY ","
FORMAT AS "CSV"
      (user_id, name, age)
)
WITH S3
(
  "provider" = "OSS",
  "s3.endpoint" = "oss-cn-hangzhou.aliyuncs.com",
  "s3.region" = "oss-cn-hangzhou",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>"
)
PROPERTIES
(
  "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
```

user_id	name	age
5	Ava	17
10	Liam	64
7	Sophia	32
9	Emma	37
1	Emily	25
4	Alexander	60
2	Benjamin	35
3	Olivia	28
6	William	69
8	James	64

```

10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Alibaba Cloud OSS and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64

```

```
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

Caution

The endpoint URLs for public and internal access are different. If the server and OSS are in the same region, it is recommended to use the internal endpoint link.

- internal endpoint: `oss-cn-hangzhou-internal.aliyuncs.com`
- public endpoint: `oss-cn-hangzhou.aliyuncs.com`

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "OSS",
  "s3.endpoint" = "oss-cn-hangzhou.aliyuncs.com",
  "s3.region" = "oss-cn-hangzhou",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
|      5 | Ava    | 17  |
|     10 | Liam   | 64  |
|      7 | Sophia | 32  |
|      9 | Emma   | 37  |
```

	1	Emily	25	
	4	Alexander	60	
	2	Benjamin	35	
	3	Olivia	28	
	6	William	69

Huawei Cloud OBS

Doris provides two ways to load files from Huawei Cloud OBS: - Use S3 Load to load Huawei Cloud OBS files into Doris, which is an asynchronous load method. - Use TVF to load Huawei Cloud OBS files into Doris, which is a synchronous load method.

Load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Huawei Cloud OBS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

```
LOAD LABEL s3_load_2022_04_01
(
  DATA INFILE("s3://your_bucket_name/s3load_example.csv")
  INTO TABLE test_s3load
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
WITH S3
(
  "provider" = "OBS",
  "s3.endpoint" = "obs.cn-north-1.myhuaweicloud.com",
  "s3.region" = "cn-north-1",
  "s3.access_key" = "<your-ak>",
```

```
"s3.secret_key" = "<your-sk>"
)
PROPERTIES
(
  "timeout" = "3600"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Result:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
| 5       | Ava    | 17  |
| 10      | Liam   | 64  |
| 7       | Sophia | 32  |
| 9       | Emma   | 37  |
| 1       | Emily  | 25  |
| 4       | Alexander | 60 |
| 2       | Benjamin | 35 |
| 3       | Olivia | 28  |
| 6       | William | 69 |
| 8       | James  | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Huawei Cloud OBS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
```

```
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "OBS",
  "s3.endpoint" = "obs.cn-north-1.myhuaweicloud.com",
  "s3.region" = "cn-north-1",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 5       | Ava       | 17  |
| 10      | Liam      | 64  |
| 7       | Sophia    | 32  |
| 9       | Emma      | 37  |
| 1       | Emily     | 25  |
| 4       | Alexander | 60  |
| 2       | Benjamin  | 35  |
| 3       | Olivia    | 28  |
| 6       | William   | 69  |
| 8       | James     | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Tencent Cloud COS

Doris provides two ways to load files from Tencent Cloud COS: - Use S3 Load to load Tencent Cloud COS files into Doris, which is an asynchronous load method. - Use TVF to load Tencent Cloud COS files into Doris, which is a synchronous load method.

Load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Tencent Cloud COS and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

```
LOAD LABEL s3_load_2022_04_01
(
  DATA INFILE("s3://your_bucket_name/s3load_example.csv")
  INTO TABLE test_s3load
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
WITH S3
(
  "provider" = "COS",
  "s3.endpoint" = "cos.ap-beijing.myqcloud.com",
  "s3.region" = "ap-beijing",
  "s3.access_key" = "<your-ak>",
```

```

"s3.secret_key" = "<your-sk>"
)
PROPERTIES
(
    "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```

mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
|      5 | Ava    | 17 |
|     10 | Liam   | 64 |
|      7 | Sophia | 32 |
|      9 | Emma   | 37 |
|      1 | Emily  | 25 |
|      4 | Alexander | 60 |
|      2 | Benjamin | 35 |
|      3 | Olivia | 28 |
|      6 | William | 69 |
|      8 | James  | 64 |
+-----+-----+-----+
10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on Tencent Cloud COS and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64

```

Step 2: Create a table in Doris

```

CREATE TABLE test_s3load(
    user_id      BIGINT      NOT NULL COMMENT "user id",
    name         VARCHAR(20) COMMENT "name",
    age         INT          COMMENT "age"
)

```

```
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "COS",
  "s3.endpoint" = "cos.ap-beijing.myqcloud.com",
  "s3.region" = "ap-beijing",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 5       | Ava       | 17  |
| 10      | Liam      | 64  |
| 7       | Sophia    | 32  |
| 9       | Emma      | 37  |
| 1       | Emily     | 25  |
| 4       | Alexander | 60  |
| 2       | Benjamin  | 35  |
| 3       | Olivia    | 28  |
| 6       | William   | 69  |
| 8       | James     | 64  |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

MinIO | Data Source

MinIO

Doris provides two ways to load files from MinIO: - Use S3 Load to load MinIO files into Doris, which is an asynchronous load method. - Use TVF to load MinIO files into Doris, which is a synchronous load method.

load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on MinIO and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

Caution

When importing data from MinIO with S3 Load, note the following:

- If MinIO is deployed in a local network without TLS, explicitly add `http://` in the endpoint, for example: `"s3.endpoint" = "http://localhost:9000"`.
- The S3 SDK uses virtual-hosted style by default, while MinIO does not enable it by default. Add `"use_path_style" = "true"` to force path-style access.

```

LOAD LABEL s3_load_2022_04_05
(
  DATA INFILE("s3://your_bucket_name/s3load_example.csv")
  INTO TABLE test_s3load
  COLUMNS TERMINATED BY ","
  FORMAT AS "CSV"
  (user_id, name, age)
)
WITH S3
(
  "provider" = "S3",
  "s3.endpoint" = "play.min.io:9000",
  "s3.region" = "us-east-1",
  "s3.access_key" = "myminioadmin",
  "s3.secret_key" = "minio-secret-key-change-me",
  "use_path_style" = "true"
)
PROPERTIES
(
  "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
```

user_id	name	age
5	Ava	17
10	Liam	64
7	Sophia	32
9	Emma	37
1	Emily	25
4	Alexander	60
2	Benjamin	35
3	Olivia	28
6	William	69
8	James	64

```

10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on MinIO and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17

```

```
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

Caution

When importing data from MinIO with TVF, note the following:

- If MinIO is deployed in a local network without TLS, explicitly add `http://` in the endpoint, for example: `"s3.endpoint" = "http://localhost:9000"`.
- The S3 SDK uses virtual-hosted style by default, while MinIO does not enable it by default. Add `"use_path_style" = "true"` to force path-style access.

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "S3",
  "s3.endpoint" = "play.min.io:9000",
  "s3.region" = "us-east-1",
  "s3.access_key" = "myminioadmin",
  "s3.secret_key" = "minio-secret-key-change-me",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int",
  "use_path_style" = "true"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name   | age |
+-----+-----+-----+
```

```
+-----+-----+
|      5 | Ava      | 17 |
|     10 | Liam     | 64 |
|      7 | Sophia   | 32 |
|      9 | Emma     | 37 |
|      1 | Emily    | 25 |
|      4 | Alexander| 60 |
|      2 | Benjamin | 35 |
|      3 | Olivia   | 28 |
|      6 | William  | 69 |
|      8 | James    | 64 |
+-----+-----+
10 rows in set (0.04 sec)
```

S3 Compatible Storage

Doris provides two ways to load files from S3 Compatible Storage: - Use S3 Load to load S3 Compatible Storage files into Doris, which is an asynchronous load method. - Use TVF to load S3 Compatible Storage files into Doris, which is a synchronous load method.

Caution

The S3 SDK uses the virtual-hosted style by default. However, some object storage systems may not enable or support virtual-hosted style access. In this case, we can add the `use_path_style` parameter to force the use of the path style.

Load with S3 Load

Use S3 Load to import files on object storage. For detailed steps, please refer to the [Broker Load Manual](#)

Step 1: Prepare the data

Create a CSV file `s3load_example.csv`. The file is stored on S3 Compatible Storage and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20) COMMENT "name",
  age          INT         COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using S3 Load

```
LOAD LABEL s3_load_2022_04_01
(
```

```

DATA INFILE("s3://your_bucket_name/s3load_example.csv")
INTO TABLE test_s3load
COLUMNS TERMINATED BY ","
FORMAT AS "CSV"
      (user_id, name, age)
)
WITH S3
(
  "provider" = "S3",
  "s3.endpoint" = "play.min.io:9000",
  "s3.region" = "us-east-1",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "use_path_style" = "true"
)
PROPERTIES
(
  "timeout" = "3600"
);

```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
```

user_id	name	age
5	Ava	17
10	Liam	64
7	Sophia	32
9	Emma	37
1	Emily	25
4	Alexander	60
2	Benjamin	35
3	Olivia	28
6	William	69
8	James	64

```

10 rows in set (0.04 sec)

```

Load with TVF

Step 1: Prepare the data

Create a CSV file s3load_example.csv The file is stored on S3 Compatible Storage and its content is as follows:

```

1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32

```

```
8,James,64
9,Emma,37
10,Liam,64
```

Step 2: Create a table in Doris

```
CREATE TABLE test_s3load(
  user_id      BIGINT      NOT NULL COMMENT "user id",
  name         VARCHAR(20)  COMMENT "name",
  age          INT          COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

Step 3: Load data using TVF

```
INSERT INTO test_s3load
SELECT * FROM S3
(
  "uri" = "s3://your_bucket_name/s3load_example.csv",
  "format" = "csv",
  "provider" = "S3",
  "s3.endpoint" = "play.min.io:9000",
  "s3.region" = "us-east-1",
  "s3.access_key" = "<your-ak>",
  "s3.secret_key" = "<your-sk>",
  "column_separator" = ",",
  "csv_schema" = "user_id:int;name:string;age:int",
  "use_path_style" = "true"
);
```

Step 4: Check the imported data

```
SELECT * FROM test_s3load;
```

Results:

```
mysql> select * from test_s3load;
+-----+-----+-----+
| user_id | name      | age |
+-----+-----+-----+
| 5 | Ava      | 17 |
| 10 | Liam     | 64 |
| 7 | Sophia   | 32 |
| 9 | Emma     | 37 |
| 1 | Emily    | 25 |
| 4 | Alexander | 60 |
| 2 | Benjamin | 35 |
| 3 | Olivia   | 28 |
| 6 | William  | 69 |
| 8 | James    | 64 |
+-----+-----+-----+
10 rows in set (0.04 sec)
```

Snowflake

During the migration from Snowflake to Doris, object storage is typically used as an intermediate medium. The core process is as follows: First, export data to object storage using Snowflake's [COPY INTO](#) statement. Then, use Doris' S3 Load feature to read data from the object storage and load it into Doris. For details, refer to [S3 Load](#).

Considerations

Before migration, select Doris' [data model](#), [partitioning](#), and [bucketing](#) strategies based on Snowflake's table structure. For more table creation strategies, refer to [Load Best Practices](#).

Data type mapping

Snowflake	Doris	Comment
NUMBER(p, s)/DECIMAL(p, s)/NUMERIC(p,s)	DECIMAL(p, s)	
INT/INTEGER	INT	
TINYINT/BYTEINT	TINYINT	
SMALLINT	SMALLINT	
BIGINT	BIGINT	
FLOAT/FLOAT4/FLOAT8/DOUBLE/DOUBLE PRECISION/REAL	DOUBLE	
VARCHAR/STRING/TEXT	VARCHAR/STRING	VARCHAR maximum length is 65535
CHAR/CHARACTER/NCHAR	CHAR	
BINARY/VARBINARY	STRING	
BOOLEAN	BOOLEAN	
DATE	DATE	
DATETIME/TIMESTAMP/TIMESTAMP_NTZ	DATETIME	TIMESTAMP is a configurable alias (default: TIMESTAMP_NTZ)
TIME	STRING	Cast to String when exporting from Snowflake
VARIANT	VARIANT	
ARRAY	ARRAY<T>	
OBJECT	JSON	
GEOGRAPHY/GEOMETRY	STRING	

1. Create Table

To migrate a Snowflake table to Doris, first create the Doris table.

Assume we have the following table and data in Snowflake:

```
CREATE OR REPLACE TABLE sales_data (  
  order_id      INT PRIMARY KEY,  
  customer_name VARCHAR(128),  
  order_date    DATE,  
  amount        DECIMAL(10,2),  
  country       VARCHAR(48)  
)  
CLUSTER BY (order_date);  
  
INSERT INTO sales_data VALUES  
(1, 'Alice', '2025-04-08', 99.99, 'USA'),  
(2, 'Bob', '2025-04-08', 149.50, 'Canada'),  
(3, 'Charlie', '2025-04-09', 75.00, 'UK'),  
(4, 'Diana', '2025-04-10', 200.00, 'Australia');
```

Based on this structure, create a Doris Primary Key partitioned table aligned with Snowflake's clustering key, partitioned by day:

```
CREATE TABLE `sales_data` (  
  order_id      INT,  
  order_date    DATE NOT NULL,  
  customer_name VARCHAR(128),  
  amount        DECIMAL(10,2),  
  country       VARCHAR(48)  
) ENGINE=OLAP  
UNIQUE KEY(`order_id`,`order_date`)  
PARTITION BY RANGE(`order_date`) (  
  PARTITION p20250408 VALUES [('2025-04-08'), ('2025-04-09')],  
  PARTITION p20250409 VALUES [('2025-04-09'), ('2025-04-10')],  
  PARTITION p20250410 VALUES [('2025-04-10'), ('2025-04-11')]  
)  
DISTRIBUTED BY HASH(`order_id`) BUCKETS 16  
PROPERTIES (  
  "dynamic_partition.enable" = "true",  
  "dynamic_partition.time_unit" = "DAY",  
  "dynamic_partition.end" = "5",  
  "dynamic_partition.prefix" = "p",  
  "dynamic_partition.buckets" = "16",  
  "replication_num" = "1"  
);
```

2. Export Data from Snowflake

2.1. Export to S3 Parquet Files via COPY INTO

Snowflake supports exporting to [AWS S3](#), [GCS](#), [AZURE](#), **Export data partitioned by Doris' partition fields**. Example for AWS S3:

```
```sql  
CREATE FILE FORMAT my_parquet_format TYPE = parquet;
```

```
CREATE OR REPLACE STAGE external_stage
URL='s3://mybucket/sales_data'
CREDENTIALS=(AWS_KEY_ID='<ak>' AWS_SECRET_KEY='<sk>')
FILE_FORMAT = my_parquet_format;

COPY INTO @external_stage from sales_data PARTITION BY (CAST(order_date AS VARCHAR)) header=true;
...
```

## 2.2. Verify Exported Files on S3

Exported files are organized into **subdirectories by partition** on S3:

```
![snowflake_s3_out_en](/images/data-operate/snowflake_s3_out_en.png)

![snowflake_s3_out2_en](/images/data-operate/snowflake_s3_out2_en.png)
```

## 3. Load Data to Doris

S3 Load is an asynchronous data load method. After execution, Doris actively pulls data from the data source. The data source supports object storage compatible with the S3 protocol, including ([AWS S3](#), [GCS](#), [AZURE](#), etc)

This method is suitable for scenarios involving large volumes of data that require asynchronous processing in the background. For data imports that need to be handled synchronously, refer to [TVF Load](#).

*Note: For **Parquet/ORC format files that contain complex types (Struct/Array/Map)**, TVF Load must be used.*

### 3.1. Load a Single Partition

```
LOAD LABEL sales_data_2025_04_08
(
 DATA INFILE("s3://mybucket/sales_data/2025_04_08/*")
 INTO TABLE sales_data
 FORMAT AS "parquet"
 (order_id, order_date, customer_name, amount, country)
)
WITH S3
(
 "provider" = "S3",
 "s3.endpoint" = "https://s3.ap-southeast-1.amazonaws.com",
 "s3.access_key" = "<ak>",
 "s3.secret_key" = "<sk>",
 "s3.region" = "ap-southeast-1"
);
```

### 3.2. Check Load Status via SHOW LOAD

Since S3 Load import is submitted asynchronously, you can check the status of a specific label using SHOW LOAD:

```
mysql> show load where label = "sales_data_2025_04_08"\G
***** 1. row *****
 JobId: 17956078
 Label: label_sales_data_2025_04_08
```

```

 State: FINISHED
 Progress: 100.00% (1/1)
 Type: BROKER
 EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=2
 TaskInfo: cluster:s3.ap-southeast-1.amazonaws.com; timeout(s):3600; max_filter_ratio:0.0;
priority:NORMAL
 ErrorMsg: NULL
 CreateTime: 2025-04-10 17:50:53
 EtlStartTime: 2025-04-10 17:50:54
 EtlFinishTime: 2025-04-10 17:50:54
 LoadStartTime: 2025-04-10 17:50:54
 LoadFinishTime: 2025-04-10 17:50:54
 URL: NULL
 JobDetails: {"Unfinished backends":{"5eec1be8612d4872-91040ff1e7208a4f":
[]},"ScannedRows":2,"TaskNumber":1,"LoadBytes":91,"All backends":{"5eec1be8612d4872-91040ff1e7208a4f":
[10022]},"FileName":1,"FileSize":1620}
 TransactionId: 766228
 ErrorTablets: {}
 User: root
 Comment:
1 row in set (0.00 sec)

```

### 3.3. Handle Load Errors

When there are multiple load tasks, you can use the following statement to query the dates and reasons for data load failures.

```

mysql> show load where state='CANCELLED' and label like "label_test%" \G
***** 1. row *****
 JobId: 18312384
 Label: label_test123
 State: CANCELLED
 Progress: 100.00% (3/3)
 Type: BROKER
 EtlInfo: unselected.rows=0; dpp.abnorm.ALL=4; dpp.norm.ALL=0
 TaskInfo: cluster:s3.ap-southeast-1.amazonaws.com; timeout(s):14400; max_filter_ratio:0.0;
priority:NORMAL

 User: root
 Comment:

```

As shown in the example above, the issue is a **data quality error**(ETL\_QUALITY\_UNSATISFIED). To view the detailed error, you need to visit the URL provided in the result. For example, the data exceeded the defined length of the country column in the table schema: `python [root@VM-10-6-centos ~]$ curl "http://10.16.10.6:28747/api/_load_error_log?file=__shard_2/error_log_insert_stmt_7602ccd7c3a4854-95307efca7bfe342_7602ccd7c3a4854-95307efca7bfe342" Reason: column_name[country], the`

length of input is too long than schema. first 32 bytes of input str: [USA] schema length: 1; actual length: 3; . src line []; Reason: column\_name[country], the length of input is too long than schema. first 32 bytes of input str: [Canada] schema length: 1; actual length: 6; . src line []; Reason: column\_name[country], the length of input is too long than schema. first 32 bytes of input str: [UK] schema length: 1; actual length: 2; . src line []; Reason: column\_name[country], the length of input is too long than schema. first 32 bytes of input str: [Australia] schema length: 1; actual length: 9; . src line [];

For data quality errors, if you want to allow skipping erroneous records, you can set a fault tolerance rate in the Properties section of the S3 Load task. For details, refer to [Import Configuration Parameters](#).

### 3.4. Load data for multiple partitions

When migrating a large volume of historical data, it is recommended to use a batch load strategy. Each batch corresponds to one or a few partitions in Doris. It is recommended to keep the data size under 100GB per batch to reduce system load and lower the cost of retries in case of load failures.

You can refer to the script [s3\\_load\\_demo.sh](#), which can poll the partition directory on S3 and submit the S3 Load task to Doris to achieve batch load.

# BigQuery

During the process of migrating BigQuery, it is usually necessary to use object storage as an intermediate medium. The core process is as follows: First, use BigQuery's [Export](#) statement to export data to GCS (Google Cloud Storage); then, use Doris's S3 Load function to read data from the object storage and load it into Doris. For details, please refer to [S3 Load](#).

## Considerations

1. Before the migration, it is necessary to select Doris' [Data Model](#), as well as the strategies for [Partitioning](#) and [Bucketing](#) according to the table structure of BigQuery. For more table creation strategies, please refer to [Load Best Practices](#).
2. When BigQuery exports data in JSON type, it does not support exporting in Parquet format. You can export it in JSON format instead.
3. When BigQuery exports data of the Time type, it is necessary to export it after casting it to the String type.

## Data type mapping

BigQuery	Doris	Comment
Array	Array	
BOOLEAN	BOOLEAN	
DATE	DATE	
DATETIME/TIMESTAMP	DATETIME	
JSON	JSON	
INT64	BIGINT	
NUMERIC	DECIMAL	
FLOAT64	DOUBLE	
STRING	VARCHAR/STRING	VARCHAR maximum length is 65535
STRUCT	STRUCT	
TIME	STRING	
OTHER	UNSUPPORTED	

## 1. Create Table

When migrating a BigQuery table to Doris, it is necessary to create a Doris table first.

Suppose we already have the following table and data in BigQuery.

```

CREATE OR REPLACE TABLE test.sales_data (
 order_id INT64,
 customer_name STRING,
 order_date DATE,
 amount NUMERIC(10,2),
 country STRING
)
PARTITION BY order_date;

INSERT INTO test.sales_data (order_id, customer_name, order_date, amount, country) VALUES
(1, 'Alice', '2025-04-08', 99.99, 'USA'),
(2, 'Bob', '2025-04-08', 149.50, 'Canada'),
(3, 'Charlie', '2025-04-09', 75.00, 'UK'),
(4, 'Diana', '2025-04-10', 200.00, 'Australia');

```

According to this table structure, a Doris primary key partitioned table can be created. The partition field should be the same as that in BigQuery, and the table should be partitioned on a daily basis.

```

CREATE TABLE `sales_data` (
 order_id INT,
 order_date DATE NOT NULL,
 customer_name VARCHAR(128),
 amount DECIMAL(10,2),
 country VARCHAR(48)
) ENGINE=OLAP
UNIQUE KEY(`order_id`,`order_date`)
PARTITION BY RANGE(`order_date`) (
 PARTITION p20250408 VALUES [('2025-04-08'), ('2025-04-09')),
 PARTITION p20250409 VALUES [('2025-04-09'), ('2025-04-10')),
 PARTITION p20250410 VALUES [('2025-04-10'), ('2025-04-11'))
)
DISTRIBUTED BY HASH(`order_id`) BUCKETS 16
PROPERTIES (
 "dynamic_partition.enable" = "true",
 "dynamic_partition.time_unit" = "DAY",
 "dynamic_partition.end" = "5",
 "dynamic_partition.prefix" = "p",
 "dynamic_partition.buckets" = "16",
 "replication_num" = "1"
);

```

## 2. Export BigQuery Data

### 2.1. Export to GCS Parquet format file through Export method

```

EXPORT DATA
 OPTIONS (
 uri = 'gs://mybucket/export/sales_data/*.parquet',
 format = 'PARQUET')
AS (
 SELECT *
 FROM test.sales_data
);

```

### 2.2. View the exported files on GCS

The above command will export the data of sales\_data to GCS, and each partition will generate one or more files with increasing file names. For details, please refer to [exporting-data](#), as follows:

The screenshot shows the Google Cloud Storage interface. The breadcrumb path is 'Buckets > [bucket name] > export > sales\_data'. Below the path are buttons: 'Create folder', 'Upload', 'Transfer data', and 'Other services'. A filter bar shows 'Filter by name prefix only' and a 'Filter' button. Below the filter bar is a table with the following data:

<input type="checkbox"/>	Name	Size	Type	Created	Storage class	Last modified
<input type="checkbox"/>	<a href="#">000000000000.parquet</a>	1.6 KB	application/octet-stream	Apr 23, 2025, 6:55:45 PM	Standard	Apr 23, 2025, 6:55:45 PM
<input type="checkbox"/>	<a href="#">000000000001.parquet</a>	1.6 KB	application/octet-stream	Apr 23, 2025, 6:55:45 PM	Standard	Apr 23, 2025, 6:55:45 PM
<input type="checkbox"/>	<a href="#">000000000002.parquet</a>	1.6 KB	application/octet-stream	Apr 23, 2025, 6:55:45 PM	Standard	Apr 23, 2025, 6:55:45 PM

gcs\_export

### 3. Load Data to Doris

S3 Load is an asynchronous data load method. After execution, Doris actively pulls data from the data source. The data source supports object storage compatible with the S3 protocol, including ([AWS S3](#), [GCS](#), [AZURE](#), etc)

This method is suitable for scenarios involving large volumes of data that require asynchronous processing in the background. For data imports that need to be handled synchronously, refer to [TVF Load](#).

*Note: For **Parquet/ORC format files that contain complex types (Struct/Array/Map)**, TVF Load must be used.*

#### 3.1. Loading data from a single file

```
LOAD LABEL sales_data_2025_04_08
(
 DATA INFILE("s3://mybucket/export/sales_data/000000000000.parquet")
 INTO TABLE sales_data
 FORMAT AS "parquet"
 (order_id, order_date, customer_name, amount, country)
)
WITH S3
(
 "provider" = "GCP",
 "s3.endpoint" = "storage.asia-southeast1.rep.googleapis.com",
 "s3.region" = "asia-southeast1",
 "s3.access_key" = "<ak>",
 "s3.secret_key" = "<sk>"
);
```

#### 3.2. Check Load Status via SHOW LOAD

Since S3 Load import is submitted asynchronously, you can check the status of a specific label using SHOW LOAD:

```
mysql> show load where label = "sales_data_2025_04_08"\G
***** 1. row *****
 JobId: 17956078
 Label: label_sales_data_2025_04_08
 State: FINISHED
```

```

Progress: 100.00% (1/1)
Type: BROKER
EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=2
TaskInfo: cluster:storage.asia-southeast1.rep.googleapis.com; timeout(s):3600; max_filter_ratio:0.0;
priority:NORMAL
ErrorMsg: NULL
CreateTime: 2025-04-10 17:50:53
EtlStartTime: 2025-04-10 17:50:54
EtlFinishTime: 2025-04-10 17:50:54
LoadStartTime: 2025-04-10 17:50:54
LoadFinishTime: 2025-04-10 17:50:54
URL: NULL
JobDetails: {"Unfinished backends":{"5eec1be8612d4872-91040ffe7208a4f":
[],"ScannedRows":2,"TaskNumber":1,"LoadBytes":91,"All backends":{"5eec1be8612d4872-91040ffe7208a4f":
[10022]},"FileName":1,"FileSize":1620}
TransactionId: 766228
ErrorTablets: {}
User: root
Comment:
1 row in set (0.00 sec)

```

### 3.3. Handle Load Errors

When there are multiple load tasks, you can use the following statement to query the dates and reasons for data load failures.

```

mysql> show load where state='CANCELLED' and label like "label_test%" \G
***** 1. row *****
JobId: 18312384
Label: label_test123
State: CANCELLED
Progress: 100.00% (3/3)
Type: BROKER
EtlInfo: unselected.rows=0; dpp.abnorm.ALL=4; dpp.norm.ALL=0
TaskInfo: cluster:storage.asia-southeast1.rep.googleapis.com; timeout(s):14400; max_filter_ratio:0.0;
priority:NORMAL
ErrorMsg: type:ETL_QUALITY_UNSATISFIED; msg:quality not good enough to cancel
CreateTime: 2025-04-15 17:32:59
EtlStartTime: 2025-04-15 17:33:02
EtlFinishTime: 2025-04-15 17:33:02
LoadStartTime: 2025-04-15 17:33:02
LoadFinishTime: 2025-04-15 17:33:02
URL: http://10.16.10.6:28747/api/_load_error_log?file=__shard_2
error_log_insert_stmt_7602ccd7c3a4854-95307efca7bfe342_7602ccd7c3a4854-95307efca7bfe342
JobDetails: {"Unfinished backends":{"7602ccd7c3a4854-95307efca7bfe341":
[],"ScannedRows":4,"TaskNumber":1,"LoadBytes":188,"All backends":{"7602ccd7c3a4854-95307efca7bfe341":
[10022]},"FileName":3,"FileSize":4839}
TransactionId: 769213
ErrorTablets: {}
User: root
Comment:

```

As shown in the example above, the issue is a **data quality error**(ETL\_QUALITY\_UNSATISFIED). To view the detailed error, you need to visit the URL provided in the result. For example, the data exceeded the defined length of the country column in the table schema:

```

[root@VM-10-6-centos ~]$ curl "http://10.16.10.6:28747/api/_load_error_log?
file=__shard_2/error_log_insert_stmt_7602ccd7c3a4854-95307efca7bfe342_7602ccd7c3a4854-95307efca7bfe342"
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str: [USA]
schema length: 1; actual length: 3; . src line [];

```

```
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str:
[Canada] schema length: 1; actual length: 6; . src line [];
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str: [UK]
schema length: 1; actual length: 2; . src line [];
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str:
[Australia] schema length: 1; actual length: 9; . src line [];
```

For data quality errors, if you want to allow skipping erroneous records, you can set a fault tolerance rate in the Properties section of the S3 Load task. For details, refer to [Load Configuration Parameters](#).

### 3.4. Loading data from multiple files

When migrating a large volume of historical data, it is recommended to use a batch load strategy. Each batch corresponds to one or a few partitions in Doris. It is recommended to keep the data size under 100GB per batch to reduce system load and lower the cost of retries in case of load failures.

You can refer to the script [s3\\_load\\_file\\_demo.sh](#), which can split the file list under the specified directory on the object storage and submit multiple S3 Load tasks to Doris in batches to achieve the effect of batch load.

# Redshift

During the process of migrating Redshift, it is usually necessary to use object storage as an intermediate medium. The core process is as follows: First, use the [UNLOAD](#) statement of Redshift to export data to the object storage; then, use the S3 Load function of Doris to read data from the object storage and import it into Doris. For details, please refer to [S3 Load](#).

## Considerations

1. Before the migration, it is necessary to select Doris' [Data Model](#), as well as the strategies for [Partitioning](#) and [Bucketing](#) according to the table structure of Redshift. For more table creation strategies, please refer to [Load Best Practices](#).
2. When Redshift exports data of the Time type, it is necessary to export it after casting it to the Varchar type.

## Data type mapping

Redshift	Doris	Comment
SMALLINT	SMALLINT	
INTEGER	INT	
BIGINT	BIGINT	
DECIMAL	DECIMAL	
REAL	FLOAT	
DOUBLE PRECISION	DOUBLE	
BOOLEAN	BOOLEAN	
CHAR	CHAR	
VARCHAR	VARCHAR/STRING	VARCHAR maximum length is 65535
DATE	DATE	
TIMESTAMP	DATETIME	
TIME/TIMEZ	STRING	
SUPER	VARIANT	
OTHER	UNSUPPORTED	

## 1. Create Table

To migrate a Redshift table to Doris, first create the Doris table.

Assume we have the following table and data in Redshift:

```
CREATE TABLE sales_data (
 order_id INTEGER,
 customer_name VARCHAR(128),
 order_date DATE,
 amount DECIMAL(10,2),
 country VARCHAR(48)
)
DISTSTYLE AUTO;

INSERT INTO sales_data VALUES
(1, 'Alice', '2025-04-08', 99.99, 'USA'),
(2, 'Bob', '2025-04-08', 149.50, 'Canada'),
(3, 'Charlie', '2025-04-09', 75.00, 'UK'),
(4, 'Diana', '2025-04-10', 200.00, 'Australia');
```

According to this table structure, a Doris primary key partitioned table can be created. The partition field should be selected according to the business scenario. Here, the partition field is “order\_date”, and it is partitioned on a daily basis.

```
CREATE TABLE `sales_data` (
 order_id INT,
 order_date DATE NOT NULL,
 customer_name VARCHAR(128),
 amount DECIMAL(10,2),
 country VARCHAR(48)
) ENGINE=OLAP
UNIQUE KEY(`order_id`,`order_date`)
PARTITION BY RANGE(`order_date`) (
 PARTITION p20250408 VALUES [('2025-04-08'), ('2025-04-09')),
 PARTITION p20250409 VALUES [('2025-04-09'), ('2025-04-10')),
 PARTITION p20250410 VALUES [('2025-04-10'), ('2025-04-11'))
)
DISTRIBUTED BY HASH(`order_id`) BUCKETS 16
PROPERTIES (
 "dynamic_partition.enable" = "true",
 "dynamic_partition.time_unit" = "DAY",
 "dynamic_partition.end" = "5",
 "dynamic_partition.prefix" = "p",
 "dynamic_partition.buckets" = "16",
 "replication_num" = "1"
);
```

## 2. Export Data from Redshift

### 2.1 Export to S3 Parquet Files via UNLOAD

When exporting to S3, export according to the **Partition field of Doris**, as follows:

```
unload ('select * from sales_data')
to 's3://mybucket/redshift/sales_data/'
iam_role 'arn:aws:iam::0123456789012:role/MyRedshiftRole'
PARQUET
PARTITION BY (order_date) INCLUDE
```

### 2.2 Verify Exported Files on S3

Exported files are organized into **subdirectories by partition** on S3:

Objects

Properties

Objects (3)

Copy S3 URI

Copy URL

Download

Open

Delete

Actions

Create folder

Objects are the fundamental entities stored in Amazon S3. You can use [Amazon S3 inventory](#) to get a list of all objects in your bucket. For others to access objects, you'll need to explicitly grant them permissions. [Learn more](#)

Find objects by prefix

<input type="checkbox"/>	Name	Type	Last modified	Size	Storage
<input type="checkbox"/>	<a href="#">order_date=2025-04-08/</a>	Folder	-	-	-
<input type="checkbox"/>	<a href="#">order_date=2025-04-09/</a>	Folder	-	-	-
<input type="checkbox"/>	<a href="#">order_date=2025-04-10/</a>	Folder	-	-	-

redshift\_out

order\_date=2025-04-08/

Objects

Properties

Objects (1)

Copy S3 URI

Copy URL

Create folder

Objects are the fundamental entities stored in Amazon S3. You can use [Amazon S3 inventory](#) to get a list of all objects in your bucket. For other objects, you'll need to explicitly grant them permissions. [Learn more](#)

Find objects by prefix

<input type="checkbox"/>	Name	Type	Last modified	Size	Storage
<input type="checkbox"/>	<a href="#">0064_part_00.parquet</a>	parquet	April 11, 2025, 17:23:17 (UTC+08:00)	1.4 KB	Standard

redshift\_out2

3. Load Data to Doris

S3 Load is an asynchronous data load method. After execution, Doris actively pulls data from the data source. The data source supports object storage compatible with the S3 protocol, including ([AWS S3](#), [GCS](#), [AZURE](#), etc)

This method is suitable for scenarios involving large volumes of data that require asynchronous processing in the background. For data imports that need to be handled synchronously, refer to [TVF Load](#).

*Note: For **Parquet/ORC format files that contain complex types (Struct/Array/Map)**, TVF Load must be used.*

3.1 Load a Single Partition

```
LOAD LABEL sales_data_2025_04_08
(
 DATA INFILE('s3://mybucket/redshift/sales_data/order_date=2025-04-08/*')
 INTO TABLE sales_data
 FORMAT AS "parquet"
 (order_id, order_date, customer_name, amount, country)
```

```

)
WITH S3
(
 "provider" = "S3",
 "s3.endpoint" = "https://s3.ap-southeast-1.amazonaws.com",
 "s3.access_key" = "<ak>",
 "s3.secret_key"="<sk>",
 "s3.region" = "ap-southeast-1"
);

```

### 3.2 Check Load Status via SHOW LOAD

Since S3 Load import is submitted asynchronously, you can check the status of a specific label using SHOW LOAD:

```

mysql> show load where label = "sales_data_2025_04_08"\G
***** 1. row *****
 JobId: 17956078
 Label: sales_data_2025_04_08
 State: FINISHED
 Progress: 100.00% (1/1)
 Type: BROKER
 EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=2
 TaskInfo: cluster:s3.ap-southeast-1.amazonaws.com; timeout(s):3600; max_filter_ratio:0.0;
 priority:NORMAL
 ErrorMsg: NULL
 CreateTime: 2025-04-10 17:50:53
 EtlStartTime: 2025-04-10 17:50:54
 EtlFinishTime: 2025-04-10 17:50:54
 LoadStartTime: 2025-04-10 17:50:54
 LoadFinishTime: 2025-04-10 17:50:54
 URL: NULL
 JobDetails: {"Unfinished backends":{"5eec1be8612d4872-91040ff1e7208a4f":
 []},"ScannedRows":2,"TaskNumber":1,"LoadBytes":91,"All backends":{"5eec1be8612d4872-91040ff1e7208a4f":
 [10022]},"FileName":1,"FileSize":1620}
 TransactionId: 766228
 ErrorTablets: {}
 User: root
 Comment:
 1 row in set (0.00 sec)

```

### 3.3 Handle Load Errors

When there are multiple load tasks, you can use the following statement to query the dates and reasons for data load failures.

```

mysql> show load where state='CANCELLED' and label like "label_test%"G
***** 1. row *****
 JobId: 18312384
 Label: label_test123
 State: CANCELLED
 Progress: 100.00% (3/3)
 Type: BROKER
 EtlInfo: unselected.rows=0; dpp.abnorm.ALL=4; dpp.norm.ALL=0
 TaskInfo: cluster:s3.ap-southeast-1.amazonaws.com; timeout(s):14400; max_filter_ratio:0.0;
 priority:NORMAL
 ErrorMsg: type:ETL_QUALITY_UNSATISFIED; msg:quality not good enough to cancel
 CreateTime: 2025-04-15 17:32:59
 EtlStartTime: 2025-04-15 17:33:02
 EtlFinishTime: 2025-04-15 17:33:02

```

```
LoadStartTime: 2025-04-15 17:33:02
LoadFinishTime: 2025-04-15 17:33:02
URL: http://10.16.10.6:28747/api/_load_error_log?
file=__shard_2/error_log_insert_stmt_7602ccd7c3a4854-95307efca7bfe342_7602ccd7c3a4854_95307efca7bfe342
JobDetails: {"Unfinished backends":{"7602ccd7c3a4854-95307efca7bfe341":
[]},"ScannedRows":4,"TaskNumber":1,"LoadBytes":188,"All backends":{"7602ccd7c3a4854-95307efca7bfe341":
[10022]},"FileName":3,"FileSize":4839}
TransactionId: 769213
ErrorTablets: {}
User: root
Comment:
```

As shown in the example above, the issue is a **data quality error**(ETL\_QUALITY\_UNSATISFIED). To view the detailed error, you need to visit the URL provided in the result. For example, the data exceeded the defined length of the country column in the table schema:

```
[root@VM-10-6-centos ~]$ curl "http://10.16.10.6:28747/api/_load_error_log?
file=__shard_2/error_log_insert_stmt_7602ccd7c3a4854-95307efca7bfe342_7602ccd7c3a4854_95307efca7bfe342"
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str: [USA]
schema length: 1; actual length: 3; . src line [];
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str:
[Canada] schema length: 1; actual length: 6; . src line [];
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str: [UK]
schema length: 1; actual length: 2; . src line [];
Reason: column_name[country], the length of input is too long than schema. first 32 bytes of input str:
[Australia] schema length: 1; actual length: 9; . src line [];
```

For data quality errors, if you want to allow skipping erroneous records, you can set a fault tolerance rate in the Properties section of the S3 Load task. For details, refer to [Import Configuration Parameters](#).

### 3.4 Load data for multiple partitions

When migrating a large volume of historical data, it is recommended to use a batch load strategy. Each batch corresponds to one or a few partitions in Doris. It is recommended to keep the data size under 100GB per batch to reduce system load and lower the cost of retries in case of load failures.

You can refer to the script [s3\\_load\\_demo.sh](#), which can poll the partition directory on S3 and submit the S3 Load task to Doris to achieve batch load.

# Migrating Data from Other OLAP

---

To migrate data from other OLAP systems to Doris, you have several options:

- For systems like Hive/Iceberg/Hudi, you can use Multi-Catalog to map them as external tables and then use “Insert Into” to load the data
- You can export data from the OLAP system into formats like CSV, and then load these data files into Doris
- You can use systems like Spark/Flink, utilizing the OLAP system’s Connector to read data, and then call the Doris Connector to write into Doris

## NOTE

If you know of other migration tools that could be added to this list, please contact [dev@doris.apache.org](mailto:dev@doris.apache.org)

# Migrating Data from Other OLTP

---

There are various ways to migrate data from other TP systems, such as MySQL/SqlServer/Oracle, to Doris.

## Multi-Catalog

Use the Catalog to map as an external table, and then use the INSERT INTO or CREATE-TABLE-AS-SELECT statements to complete the data load.

For example, with MySQL:

```
CREATE CATALOG mysql_catalog properties(
 'type' = 'jdbc',
 'user' = 'root',
 'password' = '123456',
 'jdbc_url' = 'jdbc:mysql://host:3306/mysql_db',
 'driver_url' = 'mysql-connector-java-8.0.25.jar',
 'driver_class' = 'com.mysql.cj.jdbc.Driver'
);

-- Load via INSERT
INSERT INTO internal.doris_db.tbl1
SELECT * FROM mysql_catalog.mysql_db.table1;

-- Load via CTAS
CREATE TABLE internal.doris_db.tbl1
PROPERTIES('replication_num' = '1')
AS
SELECT * FROM mysql_catalog.mysql_db.table1;
```

For more details, refer to [Catalog Data Load](#).

## Flink Doris Connector

You can leverage Flink to achieve offline and real-time synchronization for TP systems.

- Offline synchronization can be done using Flink's JDBC Source and Doris Sink to complete the data load. For example, using FlinkSQL:

```
CREATE TABLE student_source (
 id INT,
 name STRING,
 age INT
 PRIMARY KEY (id) NOT ENFORCED
) WITH (
 'connector' = 'jdbc',
 'url' = 'jdbc:mysql://localhost:3306/mydatabase',
 'table-name' = 'students',
 'username' = 'username',
 'password' = 'password',
)
;

CREATE TABLE student_sink (
 id INT,
```

```

 name STRING,
 age INT
)
 WITH (
 'connector' = 'doris',
 'fenodes' = '127.0.0.1:8030',
 'table.identifier' = 'test.students',
 'username' = 'root',
 'password' = 'password',
 'sink.label-prefix' = 'doris_label'
);

INSERT into student_sink select * from student_source;

```

For more details, refer to [Flink JDBC](#).

- Real-time synchronization can be achieved using FlinkCDC to read both full and incremental data. For example, using FlinkSQL:

```

SET 'execution.checkpointing.interval' = '10s';

CREATE TABLE cdc_mysql_source (
 id int
 ,name VARCHAR
 ,PRIMARY KEY (id) NOT ENFORCED
) WITH (
 'connector' = 'mysql-cdc',
 'hostname' = '127.0.0.1',
 'port' = '3306',
 'username' = 'root',
 'password' = 'password',
 'database-name' = 'database',
 'table-name' = 'table'
);

-- Supports synchronization of insert/update/delete events.
CREATE TABLE doris_sink (
 id INT,
 name STRING
)
WITH (
 'connector' = 'doris',
 'fenodes' = '127.0.0.1:8030',
 'table.identifier' = 'database.table',
 'username' = 'root',
 'password' = '',
 'sink.properties.format' = 'json',
 'sink.properties.read_json_by_line' = 'true',
 'sink.enable-delete' = 'true', -- Synchronize delete events.
 'sink.label-prefix' = 'doris_label'
);

insert into doris_sink select id,name from cdc_mysql_source;

```

For synchronizing an entire database or multiple tables in a TP database, you can use the full-database synchronization feature provided by the Flink Doris Connector to complete the TP database write with a single click, as shown below:

```

<FLINK_HOME>bin/flink run \
 -Dexecution.checkpointing.interval=10s \

```

```

-Dparallelism.default=1 \
-c org.apache.doris.flink.tools.cdc.CdcTools \
lib/flink-doris-connector-1.16-24.0.1.jar \
mysql-sync-database \
--database test_db \
--mysql-conf hostname=127.0.0.1 \
--mysql-conf port=3306 \
--mysql-conf username=root \
--mysql-conf password=123456 \
--mysql-conf database-name=mysql_db \
--including-tables "tbl1|test.*" \
--sink-conf fenodes=127.0.0.1:8030 \
--sink-conf username=root \
--sink-conf password=123456 \
--sink-conf jdbc-url=jdbc:mysql://127.0.0.1:9030 \
--sink-conf sink.label-prefix=label \
--table-conf replication_num=1

```

For more details, refer to [Full Database Synchronization](#)

## Spark Connector

You can use the JDBC Source and Doris Sink of the Spark Connector to complete the data write.

```

val jdbcDF = spark.read
 .format("jdbc")
 .option("url", "jdbc:postgresql:dbserver")
 .option("dbtable", "schema.tablename")
 .option("user", "username")
 .option("password", "password")
 .load()

jdbcDF.write.format("doris")
 .option("doris.table.identifier", "db.table")
 .option("doris.fenodes", "127.0.0.1:8030")
 .option("user", "root")
 .option("password", "")
 .save()

```

For more details, refer to [JDBC To Other Databases](#), [Spark Doris Connector](#)

## DataX / Seatunnel / CloudCanal and other third-party tools.

In addition, you can also use third-party synchronization tools for data synchronization. For more details, please refer to: - [DataX](#) - [Seatunnel](#) - [CloudCanal](#)

# Stream Load

---

Stream Load supports importing local files or data streams into Doris through the HTTP protocol.

Stream Load is a synchronous import method that returns the import result after the import is executed, allowing you to determine the success of the import through the request response. Generally, users can use Stream Load to import files under 10GB. If the file is too large, it is recommended to split the file and then use Stream Load for importing. Stream Load can ensure the atomicity of a batch of import tasks, meaning that either all of them succeed or all of them fail.

**In comparison to single-threaded load using `curl`, Doris Streamloader is a client tool designed for loading data into Apache Doris. It reduces the ingestion latency of large datasets by its concurrent loading capabilities. It comes with the following features:**

- **Parallel loading:** multi-threaded load for the Stream Load method. You can set the parallelism level using the `workers` parameter.
- **Multi-file load:** simultaneously loading of multiple files and directories with one shot. It supports recursive file fetching and allows you to specify file names with wildcard characters.
- **Path traversal support:** supports path traversal when the source files are in directories
- **Resilience and continuity:** in case of partial load failures, it can resume data loading from the point of failure.
- **Automatic retry mechanism:** in case of loading failures, it can automatically retry a default number of times. If the loading remains unsuccessful, it will print the command for manual retry.

See [Doris Streamloader](#) for detailed instructions and best practices.

## User guide

Stream Load supports importing CSV, JSON, Parquet, and ORC format data from local or remote sources via HTTP.

- **Null values:** Use `\N` to represent null. For example, `a,\N,b` indicates the middle column is null.
- **Empty string:** An empty string is represented when there are no characters between two delimiters. For example, in `a,,b`, there are no characters between the two commas, indicating that the middle column value is an empty string.

## Basic principles

When using Stream Load, it is necessary to initiate an import job through the HTTP protocol to the FE (Frontend) node. The FE will redirect the request to a BE (Backend) node in a round-robin manner to achieve load balancing. It is also possible to send HTTP requests directly to a specific BE node. In Stream Load, Doris selects one node to serve as the Coordinator node. The Coordinator node is responsible for receiving data and distributing it to other nodes.

The following figure shows the main flow of Stream Load, omitting some import details.

### Basic principles

1. The client submits a Stream Load imports job request to the FE (Frontend).
2. The FE selects a BE (Backend) as the Coordinator node in a round-robin manner, which is responsible for scheduling the import job, and then returns an HTTP redirect to the client.
3. The client connects to the Coordinator BE node and submits the import request.
4. The Coordinator BE distributes the data to the appropriate BE nodes and returns the import result to the client once the import is complete.
5. Alternatively, the client can directly specify a BE node as the Coordinator and distribute the import job directly.

## Quick start

Stream Load import data through the HTTP protocol. The following example uses the curl tool to demonstrate submitting an import job through Stream Load.

### Prerequisite check

Stream Load requires INSERT privileges on the target table. If there are no INSERT privileges, it can be granted to the user through the [GRANT](#) command.

### Create load job

#### Loading CSV

1. Creating loading data

Create a CSV file named `streamload_example.csv`. The specific content is as follows

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
```

```
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

## 2. Creating a table for loading

Create the table that will be imported into, using the specific syntax as follows:

```
CREATE TABLE testdb.test_streamload(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User name",
 age INT COMMENT "User age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

## 3. Enable the load job

The Stream Load job can be submitted using the `curl` command.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

Stream Load is a synchronous method, where the result is directly returned to the user.

```
{
 "TxnId": 3,
 "Label": "123",
 "Comment": "",
 "TwoPhaseCommit": "false",
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 10,
 "NumberLoadedRows": 10,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 118,
 "LoadTimeMs": 173,
 "BeginTxnTimeMs": 1,
 "StreamLoadPutTimeMs": 70,
 "ReadDataTimeMs": 2,
 "WriteDataTimeMs": 48,
 "CommitAndPublishTimeMs": 52
}
```

## 4. View data

```
mysql> select count(*) from testdb.test_streamload;
+-----+
| count(*) |
+-----+
```

## Loading JSON

### 1. Creating loading data

Create a JSON file named `streamload_example.json`. The specific content is as follows

```
[
{"userid":1,"username":"Emily","userage":25},
{"userid":2,"username":"Benjamin","userage":35},
{"userid":3,"username":"Olivia","userage":28},
{"userid":4,"username":"Alexander","userage":60},
{"userid":5,"username":"Ava","userage":17},
{"userid":6,"username":"William","userage":69},
{"userid":7,"username":"Sophia","userage":32},
{"userid":8,"username":"James","userage":64},
{"userid":9,"username":"Emma","userage":37},
{"userid":10,"username":"Liam","userage":64}
]
```

### 2. Creating a table for loading

Create the table that will be imported into, using the specific syntax as follows:

```
CREATE TABLE testdb.test_streamload(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User name",
 age INT COMMENT "User age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

### 3. Enabling the load job

The Stream Load job can be submitted using the `curl` command.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "label:124" \
-H "Expect:100-continue" \
-H "format:json" -H "strip_outer_array:true" \
-H "jsonpaths:[\"$.userid\", \"$.username\", \"$.userage\"]" \
-H "columns:user_id,name,age" \
-T streamload_example.json \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

#### Note

If the JSON file is not a JSON array but each line is a JSON object, add the headers `-H "strip_outer_array:false"` and `-H "read_json_by_line:true"`.

If you need to load the JSON object at the root node of a JSON file, the jsonpaths should be specified as \$., e.g., `-H "jsonpaths:['$']"`

Stream Load is a synchronous method, where the result is directly returned to the user.

```
{
 "TxnId": 7,
 "Label": "125",
 "Comment": "",
 "TwoPhaseCommit": "false",
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 10,
 "NumberLoadedRows": 10,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 471,
 "LoadTimeMs": 52,
 "BeginTxnTimeMs": 0,
 "StreamLoadPutTimeMs": 11,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 23,
 "CommitAndPublishTimeMs": 16
}
```

## View load job

By default, Stream Load synchronously returns results to the client, so the system does not record Stream Load historical jobs. If recording is required, add the configuration `enable_stream_load_record=true` in `be.conf`. Refer to the [BE configuration options](#) for specific details.

After configuring, you can use the `show stream load` command to view completed Stream Load jobs.

```
mysql> show stream load from testdb;
```

Label	Db	Table	ClientIp	Status	Message	Url	TotalRows	LoadedRows	FilteredRows	UnselectedRows	LoadBytes	StartTime	FinishTime	User
12356	testdb	test_streamload	192.168.88.31	Success	OK	N/A	10	10	0	118		2023-11-29 08:53:00.594	2023-11-29 08:53:00.650	root

1 row in set (0.00 sec)

## Cancel load job

Users cannot manually cancel a Stream Load operation. A Stream Load job will be automatically canceled by the system if it encounters a timeout (set to 0) or an import error.

## Reference manual

### Command

The syntax for Stream Load is as follows:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" [-H ""...] \
-T <file_path> \
-XPUT http://fe_host:http_port/api/{db}/{table}/_stream_load
```

Stream Load operation supports both HTTP chunked and non-chunked import methods. For non-chunked imports, it is necessary to have a Content-Length header to indicate the length of the uploaded content, which ensures data integrity.

### Load configuration parameters

#### FE configuration

##### 1. stream\_load\_default\_timeout\_second

- Default Value: 259200 (s)
- Dynamic Configuration: Yes
- FE Master-only Configuration: Yes

Parameter Description: The default timeout for Stream Load. The load job will be canceled by the system if it is not completed within the set timeout (in seconds). If the source file cannot be imported within the specified time, the user can set an individual timeout in the Stream Load request. Alternatively, adjust the stream\_load\_default\_timeout\_second parameter on the FE to set the global default timeout.

#### BE configuration

##### 1. streaming\_load\_max\_mb

- Default value: 10240 (MB)
- Dynamic configuration: Yes
- Parameter description: The maximum import size for Stream Load. If the user's original file exceeds this value, the streaming\_load\_max\_mb parameter on the BE needs to be adjusted.

##### 2. Header parameters

Load parameters can be passed through the HTTP Header section. See below for specific parameter descriptions.

Parameters	Parameters description
label	Used to specify a label for this Doris import. Data with the same label cannot be imported multiple times. If no label is specified, Doris will automatically generate one. Users can avoid duplicate imports of the same data by specifying a label. Doris retains import job labels for three days by default, but this duration can be adjusted using <code>label_keep_max_second</code> . For example, to specify the label for this import as 123, use the command <code>-H "label:123"</code> . The use of labels prevents users from importing the same data repeatedly. It is strongly recommended that users use the same label for the same batch of data. This ensures that duplicate requests for the same batch of data are only accepted once, guaranteeing At-Most-Once semantics. When the status of an import job corresponding to a label is CANCELLED, that label can be used again.
column_separator	Used to specify the column separator in the import file, which defaults to <code>\t</code> . If the separator is an invisible character, it needs to be prefixed with <code>\x</code> and represented in hexadecimal format. Multiple characters can be combined as a column separator. For example, to specify the separator as <code>\x01</code> for a Hive file, use the command <code>-H "column_separator:\x01"</code> .
line_delimiter	Used to specify the line delimiter in the import file, which defaults to <code>\n</code> . Multiple characters can be combined as a line delimiter. For example, to specify the line delimiter as <code>\n</code> , use the command <code>-H "line_delimiter:\n"</code> .
columns	Used to specify the correspondence between columns in the import file and columns in the table. If the columns in the source file exactly match the content of the table, this field does not need to be specified. If the schema of the source file does not match the table, this field is required for data transformation. There are two formats: direct column correspondence to fields in the import file, and derived columns represented by expressions. Refer to <a href="#">Data Transformation</a> for detailed examples.
where	Used to filter out unnecessary data. If users need to exclude certain data, they can achieve this by setting this option. For example, to import only data where the k1 column is equal to 20180601, specify <code>-H "where: k1 = 20180601"</code> during the import.
max_filter_ratio	Used to specify the maximum tolerable ratio of filterable (irregular or otherwise problematic) data, which defaults to zero tolerance. The value range is 0 to 1. If the error rate of the imported data exceeds this value, the import will fail. Irregular data does not include rows filtered out by the where condition. For example, to maximize the import of all correct data (100% tolerance), specify the command <code>-H "max_filter_ratio:1"</code> .
partitions	Used to specify the partitions involved in this import. If users can determine the corresponding partitions for the data, it is recommended to specify this option. Data that does not meet these partition criteria will be filtered out. For example, to specify importing into partitions p1 and p2, use the command <code>-H "partitions: p1, p2"</code> .
timeout	Used to specify the timeout for the import in seconds. The default is 600 seconds, and the configurable range is from 1 second to 259200 seconds. For example, to specify an import timeout of 1200 seconds, use the command <code>-H "timeout:1200"</code> .
strict_mode	Used to specify whether to enable strict mode for this import, which is disabled by default. For example, to enable strict mode, use the command <code>-H "strict_mode:true"</code> .
timezone	Used to specify the timezone to be used for this import, which defaults to GMT+8. This parameter affects the results of all timezone-related functions involved in the import. For example, to specify the import timezone as Africa/Abidjan, use the command <code>-H "timezone:Africa/Abidjan"</code> .
exec_mem_limit	The memory limit for the import, which defaults to 2GB. The unit is bytes.

Parameters	Parameters description
format	Used to specify the format of the imported data, which defaults to CSV. Currently supported formats include: CSV, JSON, arrow, csv_with_names (supports filtering the first row of the csv file), csv_with_names_and_types (supports filtering the first two rows of the csv file), Parquet, and ORC. For example, to specify the imported data format as JSON, use the command <code>-H "format:json"</code> .
jsonpaths	There are two ways to import JSON data format: Simple Mode and Matching Mode. If no jsonpaths are specified, it is the simple mode that requires the JSON data to be of the object type. Matching mode used when the JSON data is relatively complex and requires matching the corresponding values through the jsonpaths parameter. In simple mode, the keys in JSON are required to correspond one-to-one with the column names in the table. For example, in the JSON data <code>{"k1":1, "k2":2, "k3":"hello"}</code> , k1, k2, and k3 correspond to the columns in the table respectively.
strip_outer_array	When strip_outer_array is set to true, it indicates that the JSON data starts with an array object and flattens the objects within the array. The default value is false. When the outermost layer of the JSON data is represented by <code>[]</code> , which denotes an array, strip_outer_array should be set to true. For example, with the following data, setting strip_outer_array to true will result in two rows of data being generated when imported into Doris: <code>[{"k1": 1, "v1": 2}, {"k1": 3, "v1": 4}]</code> .
json_root	json_root is a valid jsonpath string that specifies the root node of a JSON document, with a default value of <code>""</code> .
merge_type	The merge type of data. Three types are supported: - APPEND (default): Indicates that all data in this batch will be appended to existing data - DELETE: Indicates deletion of all rows with Keys matching this batch of data - MERGE: Must be used in conjunction with DELETE conditions. Data meeting DELETE conditions will be processed according to DELETE semantics, while the rest will be processed according to APPEND semantics For example, to specify merge mode as MERGE: <code>-H "merge_type: MERGE" -H "delete: flag=1"</code>
delete	It is only meaningful under MERGE, representing the deletion conditions for data.
function_column.sequence_col	It is suitable only for the UNIQUE KEYS model. Within the same Key column, it ensures that the Value column is replaced according to the specified source_sequence column. The source_sequence can either be a column from the data source or an existing column in the table structure.
fuzzy_parse	It is a boolean type. If set to true, the JSON will be parsed with the first row as the schema. Enabling this option can improve the efficiency of JSON imports, but it requires that the order of the keys in all JSON objects be consistent with the first line. The default is false and it is only used for JSON format.
num_as_string	It is a boolean type. When set to true, indicates that numeric types will be converted to strings during JSON parsing to ensure no loss of precision during the import process.
read_json_by_line	It is a boolean type. When set to true, indicates support for reading one JSON object per line, defaulting to false.
send_batch_parallelism	Sets the parallelism for the parallelism for sending batch-processed data. If the parallelism value exceeds the max_send_batch_parallelism_per_job configured in BE, the coordinating BE will use the max_send_batch_parallelism_per_job value.
hidden_columns	Used to specify hidden columns in the imported data, which takes effect when the Header does not include Columns. Multiple hidden columns are separated by commas. The system will use the user-specified data for import. In the following example, the last column of data in the imported data is <code>__DORIS_SEQUENCE_COL__</code> . hidden_columns: <code>__DORIS_DELETE_SIGN__, __DORIS_SEQUENCE_COL__</code> .

Parameters	Parameters description
load_to_single_tablet	It is a boolean type. When set to true, indicates support for importing data only to a single Tablet corresponding to the partition, defaulting to false. This parameter is only allowed when importing to an OLAP table with random bucketing.
compress_type	Currently, only compression of CSV files is supported. Compression formats include gz, lzo, bz2, lz4, lzop, and deflate.
trim_double_quotes	It is a boolean type. When set to true, indicates trimming of the outermost double quotes for each field in the CSV file, defaulting to false.
skip_lines	It is an integer type. Used to specify the number of lines to skip at the beginning of the CSV file, defaulting to 0. When the format is set to csv_with_names or csv_with_names_and_types, this parameter will become invalid.
comment	It is a String type, with an empty string as the default value. Used to add additional information to the task.
enclose	Specify the enclosure character. When a CSV data field contains a row delimiter or column delimiter, to prevent unexpected truncation, you can specify a single-byte character as the enclosure for protection. For example, if the column delimiter is ",", and the enclosure is "'", the data "a,b,c" will have "b,c" parsed as a single field. Note: When the enclosure is set to a double quote ("), make sure to set trim_double_quotes to true.
escape	Specify the escape character. It is used to escape characters that are the same as the enclosure character within a field. For example, if the data is "a,b,'c'", and the enclosure is "'", and you want "b,'c'" to be parsed as a single field, you need to specify a single-byte escape character, such as "\", and modify the data to "a,b,'c'".
memtable_on_sink_node	Whether to enable MemTable on DataSink node when loading data, default is false.
unique_key_update_mode	The update modes on Unique tables, currently are only effective for Merge-On-Write Unique tables. Supporting three types: UPSERT, UPDATE_FIXED_COLUMNS, and UPDATE_FLEXIBLE_COLUMNS. UPSERT: Indicates that data is loaded with upsert semantics; UPDATE_FIXED_COLUMNS: Indicates that data is loaded through partial updates; UPDATE_FLEXIBLE_COLUMNS: Indicates that data is loaded through flexible partial updates.

## Load return value

Stream Load is a synchronous import method, and the load result is directly provided to the user through the creation of an load return value, as shown below:

```
{
 "TxnId": 1003,
 "Label": "b6f3bc78-0d2c-45d9-9e4c-faa0a0149bee",
 "Status": "Success",
 "ExistingJobStatus": "FINISHED", // optional
 "Message": "OK",
 "NumberTotalRows": 1000000,
 "NumberLoadedRows": 1000000,
 "NumberFilteredRows": 1,
 "NumberUnselectedRows": 0,
 "LoadBytes": 40888898,
 "LoadTimeMs": 2144,
 "BeginTxnTimeMs": 1,
 "StreamLoadPutTimeMs": 2,
 "ReadDataTimeMs": 325,
 "WriteDataTimeMs": 1933,
 "CommitAndPublishTimeMs": 106,
 "ErrorURL": "http://192.168.1.1:8042/api/_load_error_log?"
```

```
file=__shard_0/error_log_insert_stmt_db18266d4d9b4ee5-abb00ddd64bdf005_db18266d4d9b4ee5-abb00ddd64bdf005"
}
```

The return result parameters are explained in the following table:

Parameters	Parameters description
TxnId	Import transaction ID
Label	Label of load job, specified via -H "label:<label_id>".
Status	Final load Status. <b>Success</b> : The load job was successful. <b>Publish Timeout</b> : The load job has been completed, but there may be a delay in data visibility. <b>Label Already Exists</b> : The label is duplicated, requiring a new label. <b>Fail</b> : The load job failed.
ExistingJobStatus	The status of the load job corresponding to the already existing label. This field is only displayed when the Status is <b>Label Already Exists</b> . Users can use this status to know the status of the import job corresponding to the existing label. <b>RUNNING</b> means the job is still executing, and <b>FINISHED</b> means the job was successful.
Message	Error information related to the load job.
NumberTotalRows	The total number of rows processed during the load job.
NumberLoadedRows	The number of rows that were successfully loaded.
NumberFilteredRows	The number of rows that did not meet the data quality standards.
NumberUnselectedRows	The number of rows that were filtered out based on the WHERE condition.
LoadBytes	The amount of data in bytes.
LoadTimeMs	The time taken for the load job to complete, measured in milliseconds.
BeginTxnTimeMs	The time taken to request the initiation of a transaction from the Frontend node (FE), measured in milliseconds.
StreamLoadPutTimeMs	The time taken to request the execution plan for the load job data from the FE, measured in milliseconds.
ReadDataTimeMs	The time spent reading the data during the load job, measured in milliseconds.
WriteDataTimeMs	The time taken to perform the data writing operations during the load job, measured in milliseconds.
CommitAndPublishTimeMs	The time taken to request the commit and publish the transaction from the FE, measured in milliseconds.
ErrorURL	If there are data quality issues, users can access this URL to view the specific rows with errors.

Users can access the ErrorURL to review data that failed to import due to issues with data quality. By executing the command `curl "<ErrorURL>"`, users can directly retrieve information about the erroneous data.

## Load example

### Setting load timeout and maximum size

The timeout for a load job is measured in seconds. If the load job is not completed within the specified timeout period, it will be cancelled by the system and marked as CANCELLED. You can adjust the timeout for a Stream Load job by specifying the `timeout` parameter or adding the `stream_load_default_timeout_second` parameter in the `fe.conf` file.

Before initiating the load, you need to calculate the timeout based on the file size. For example, for a 100GB file with an estimated load performance of 50MB/s:

```
Load time ≈ 100GB / 50MB/s ≈ 2048s
```

You can use the following command to specify a timeout of 3000 seconds for creating a Stream Load job:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "timeout:3000" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Setting maximum error tolerance rate

Load job can tolerate a certain amount of data with formatting errors. The tolerance rate is configured using the `max_filter_ratio` parameter. By default, it is set to 0, meaning that if there is even a single erroneous data row, the entire load job will fail. If users wish to ignore some problematic data rows, they can set this parameter to a value between 0 and 1. Doris will automatically skip rows with incorrect data formats. For more information on calculating the tolerance rate, please refer to the [Data Transformation](#) documentation.

You can use the following command to specify a `max_filter_ratio` tolerance of 0.4 for creating a Stream Load job:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "max_filter_ratio:0.4" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Setting load filtering conditions

During the load job, you can use the WHERE parameter to apply conditional filtering to the imported data. The filtered data will not be included in the calculation of the filter ratio and will not affect the setting of `max_filter_ratio`. After the load job is complete, you can view the number of filtered rows by checking `num_rows_unselected`.

You can use the following command to specify WHERE filtering conditions for creating a Stream Load job:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "where:age>=35" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading data into specific partitions

Loading data from local files into partitions p1 and p2 of the table, allowing a 20% error rate.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "label:123" \
-H "Expect:100-continue" \
-H "max_filter_ratio:0.2" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-H "partitions: p1, p2" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading data into specific timezone

Since Doris currently does not have a built-in time zone time type, all DATETIME related types only represent absolute time points, do not contain time zone information, and will not change due to changes in the Doris system time zone. Therefore, for the import of data with time zones, our unified processing method is to convert it into data in a specific target time zone. In the Doris system, it is the time zone represented by the session variable `time_zone`.

In the import, our target time zone is specified through the parameter `timezone`. This variable will replace the session variable `time_zone` when time zone conversion occurs and time zone sensitive functions are calculated. Therefore, if there are no special circumstances, the `timezone` should be set in the import transaction to be consistent with the `time_zone` of the current Doris cluster. This means that all time data with a time zone will be converted to this time zone.

For example, the Doris system time zone is "+08:00", and the time column in the imported data contains two pieces of data, namely "2012-01-01 01:00:00+00:00" and "2015-12-12 12:12:12-08:00", then after we specify the time zone of the imported transaction through `-H "timezone: +08:00"` when importing, both pieces of data will be converted to the time zone to obtain the result. "2012-01-01 09:00:00" and "2015-12-13 04:12:12".

For more information on time zone interpretation, please refer to the document [Time Zone](#).

## Streamingly import

Stream Load is based on the HTTP protocol for importing, which supports using programming languages such as Java, Go, or Python for streaming import. This is why it is named Stream Load.

The following example demonstrates this usage through a bash command pipeline. The imported data is generated streamingly by the program rather than from a local file.

```
seq 1 10 | awk '{OFS="\t"}{print $1, $1 * 10}' | curl --location-trusted -u root -T -
http://host:port/api/testDb/testTbl/_stream_load
```

## Set CSV first row filtering

File data:

```
id,name,age
1,doris,20
2,flink,10
```

Filtering the first row during load by specifying `format=csv_with_names`

```
curl --location-trusted -u root -T test.csv -H "label:1" -H "format:csv_with_names" -H "column_separator:,"
http://host:port/api/testDb/testTbl/_stream_load
```

## Specifying `merge_type` for DELETE operations

In Stream Load, there are three import types: APPEND, DELETE, and MERGE. These can be adjusted by specifying the parameter `merge_type`. If you want to specify that all data with the same key as the imported data should be deleted, you can use the following command:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "merge_type: DELETE" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

Before loading:

siteid	citycode	username	pv
3	2	tom	2
4	3	bush	3
5	3	helen	3

The imported data is:

```
3,2,tom,0
```

After importing, the original table data will be deleted, resulting in the following result:

siteid	citycode	username	pv
4	3	bush	3
5	3	helen	3

## Specifying `merge_type` for MERGE operation

By specifying `merge_type` as MERGE, the imported data can be merged into the table. The MERGE semantics need to be used in combination with the DELETE condition, which means that data satisfying the DELETE condition is processed according to the DELETE semantics, and the rest is added to the table according to the

APPEND semantics. The following operation represents deleting the row with `siteid` of 1, and adding the rest of the data to the table:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "merge_type: MERGE" \
-H "delete: siteid=1" \
-H "column_separator:," \
-H "columns:user_id,name,age" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

Before loading:

siteid	citycode	username	pv
4	3	bush	3
5	3	helen	3
1	1	jim	2

The imported data is:

```
2,1,grace,2
3,2,tom,2
1,1,jim,2
```

After loading, the row with `siteid = 1` will be deleted according to the condition, and the rows with `siteid` of 2 and 3 will be added to the table:

siteid	citycode	username	pv
4	3	bush	3
2	1	grace	2
3	2	tom	2
5	3	helen	3

## Specifying sequence column for merge

When a table with a Unique Key has a Sequence column, the value of the Sequence column serves as the basis for the replacement order in the REPLACE aggregation function under the same Key column. A larger value can replace a smaller one. When marking deletions based on `DORIS_DELETE_SIGN` for such a table, it is necessary to ensure that the Key is the same and that the Sequence column value is greater than or equal to the current value. By specifying the `function_column.sequence_col` parameter, deletion operations can be performed in combination with `merge_type: DELETE`.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "merge_type: DELETE" \
-H "function_column.sequence_col: age" \
```

```
-H "column_separator:," \
-H "columns: name, gender, age"
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

Given the following table schema:

```
SET show_hidden_columns=true;
Query OK, 0 rows affected (0.00 sec)
```

```
DESC table1;
```

Field	Type	Null	Key	Default	Extra
name	VARCHAR(100)	No	true	NULL	
gender	VARCHAR(10)	Yes	false	NULL	REPLACE
age	INT	Yes	false	NULL	REPLACE
__DORIS_DELETE_SIGN__	TINYINT	No	false	0	REPLACE
__DORIS_SEQUENCE_COL__	INT	Yes	false	NULL	REPLACE

4 rows in set (0.00 sec)

The original table data is:

name	gender	age
li	male	10
wang	male	14
zhang	male	12

1. Sequence parameter takes Effect, loading sequence column value is larger than or equal to the existing data in the table.

loading data as:

```
li,male,10
```

Since function\_column.sequence\_col is specified as age, and the age value is larger than or equal to the existing column in the table, the original table data is deleted. The table data becomes:

name	gender	age
wang	male	14
zhang	male	12

2. Sequence parameter do not take effect, loading sequence column value is less than or equal to the existing data in the table:

loading data as:

```
li,male,9
```

Since `function_column.sequence_col` is specified as `age`, but the `age` value is less than the existing column in the table, the delete operation does not take effect. The table data remains unchanged, and the row with the primary key of `li` is still visible:

name	gender	age
li	male	10
wang	male	14
zhang	male	12

It is not deleted because that, at the underlying dependency level, it first checks for rows with the same key. It displays the row data with the larger sequence column value. Then, it checks the `DORIS_DELETE_SIGN` value for that row. If it is 1, it is not displayed externally. If it is 0, it is still read and displayed.

## Loading data with enclosing characters

When the data in a CSV file contains delimiters or separators, single-byte characters can be specified as enclosing characters to protect the data from being truncated.

For example, in the following data where a comma is used as the separator but also exists within a field:

```
zhangsan,30,'Shanghai, HuangPu District, Dagu Road'
```

By specifying an enclosing character such as a single quotation mark `'`, the entire `Shanghai, HuangPu District, Dagu Road` can be treated as a single field.

```
curl --location-trusted -u <doris_user>:<doris_password> \
 -H "Expect:100-continue" \
 -H "column_separator:," \
 -H "enclose:''" \
 -H "columns:username,age,address" \
 -T streamload_example.csv \
 -XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

If the enclosing character also appears within a field, such as wanting to treat `Shanghai City, Huangpu District, \ 'Dagu Road` as a single field, it is necessary to first perform string escaping within the column:

```
Zhang San,30,'Shanghai, Huangpu District, \'Dagu Road'
```

An escape character, which is a single-byte character, can be specified using the `escape` parameter. In the example, the backslash `\` is used as the escape character.

```
curl --location-trusted -u <doris_user>:<doris_password> \
 -H "Expect:100-continue" \
 -H "column_separator:," \
 -H "enclose:''" \
 -H "escape:\\\" \
 -T streamload_example.csv \
 -XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

```
-H "columns:username,age,address" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading fields containing default CURRENT\_TIMESTAMP type

Here's an example of loading data into a table that contains a field with the DEFAULT CURRENT\_TIMESTAMP type:

Table schema:

```
`id` bigint(30) NOT NULL,
`order_code` varchar(30) DEFAULT NULL COMMENT '',
`create_time` datetimedv2(3) DEFAULT CURRENT_TIMESTAMP
```

JSON data type:

```
{"id":1,"order_Code":"avc"}
```

Command:

```
curl --location-trusted -u root -T test.json -H "label:1" -H "format:json" -H 'columns: id, order_code,
create_time=CURRENT_TIMESTAMP()' http://host:port/api/testDb/testTbl/_stream_load
```

## Simple mode for loading JSON format data

When the JSON fields correspond one-to-one with the column names in the table, you can import JSON data format into the table by specifying the parameters “strip\_outer\_array:true” and “format:json”.

For example, if the table is defined as follows:

```
CREATE TABLE testdb.test_streamload(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User name",
 age INT COMMENT "User age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

And the data field names correspond one-to-one with the column names in the table:

```
[
 {"user_id":1,"name":"Emily","age":25},
 {"user_id":2,"name":"Benjamin","age":35},
 {"user_id":3,"name":"Olivia","age":28},
 {"user_id":4,"name":"Alexander","age":60},
 {"user_id":5,"name":"Ava","age":17},
 {"user_id":6,"name":"William","age":69},
 {"user_id":7,"name":"Sophia","age":32},
 {"user_id":8,"name":"James","age":64},
 {"user_id":9,"name":"Emma","age":37},
```

```
{ "user_id":10,"name":"Liam","age":64}
]
```

You can use the following command to load JSON data into the table:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "format:json" \
-H "strip_outer_array:true" \
-T streamload_example.json \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Matching mode for loading complex JSON format data

When the JSON data is more complex and cannot correspond one-to-one with the column names in the table, or there are extra columns, you can use the `jsonpaths` parameter to complete the column name mapping and perform data matching import. For example, with the following data:

```
[
{"userid":1,"hudi":"lala","username":"Emily","userage":25,"userhp":101},
{"userid":2,"hudi":"kpkp","username":"Benjamin","userage":35,"userhp":102},
{"userid":3,"hudi":"ji","username":"Olivia","userage":28,"userhp":103},
{"userid":4,"hudi":"popo","username":"Alexander","userage":60,"userhp":103},
{"userid":5,"hudi":"uio","username":"Ava","userage":17,"userhp":104},
{"userid":6,"hudi":"lkj","username":"William","userage":69,"userhp":105},
{"userid":7,"hudi":"komf","username":"Sophia","userage":32,"userhp":106},
{"userid":8,"hudi":"mki","username":"James","userage":64,"userhp":107},
{"userid":9,"hudi":"hjk","username":"Emma","userage":37,"userhp":108},
{"userid":10,"hudi":"hua","username":"Liam","userage":64,"userhp":109}
]
```

You can specify the `jsonpaths` parameter to match the specified columns:

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "format:json" \
-H "strip_outer_array:true" \
-H "jsonpaths:[\"$.userid\", \"$.username\", \"$.userage\"]" \
-H "columns:user_id,name,age" \
-T streamload_example.json \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Specifying JSON root node for data load

If the JSON data contains nested JSON fields, you need to specify the root node of the imported JSON. The default value is `""`.

For example, with the following data, if you want to import the data in the `comment` column into the table:

```
[
{"user":1,"comment":{"userid":101,"username":"Emily","userage":25}},
{"user":2,"comment":{"userid":102,"username":"Benjamin","userage":35}},
{"user":3,"comment":{"userid":103,"username":"Olivia","userage":28}},
{"user":4,"comment":{"userid":104,"username":"Alexander","userage":60}},
]
```

```
{
 "user": 5, "comment": {"userid": 105, "username": "Ava", "userage": 17},
 "user": 6, "comment": {"userid": 106, "username": "William", "userage": 69},
 "user": 7, "comment": {"userid": 107, "username": "Sophia", "userage": 32},
 "user": 8, "comment": {"userid": 108, "username": "James", "userage": 64},
 "user": 9, "comment": {"userid": 109, "username": "Emma", "userage": 37},
 "user": 10, "comment": {"userid": 110, "username": "Liam", "userage": 64}
}
```

First, you need to specify the root node as comment using the `json_root` parameter, and then complete the column name mapping according to the `jsonpaths` parameter.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "format:json" \
-H "strip_outer_array:true" \
-H "json_root: $.comment" \
-H "jsonpaths: [\"$.userid\", \"$.username\", \"$.userage\"]" \
-H "columns:user_id,name,age" \
-T streamload_example.json \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading array data type

For example, if the following data contains an array type:

```
1|Emily|[1,2,3,4]
2|Benjamin|[22,45,90,12]
3|Olivia|[23,16,19,16]
4|Alexander|[123,234,456]
5|Ava|[12,15,789]
6|William|[57,68,97]
7|Sophia|[46,47,49]
8|James|[110,127,128]
9|Emma|[19,18,123,446]
10|Liam|[89,87,96,12]
```

Load data into the following table structure:

```
CREATE TABLE testdb.test_streamload(
 typ_id BIGINT NOT NULL COMMENT "ID",
 name VARCHAR(20) NULL COMMENT "Name",
 arr ARRAY<int(10)> NULL COMMENT "Array"
)
DUPLICATE KEY(typ_id)
DISTRIBUTED BY HASH(typ_id) BUCKETS 10;
```

You can directly load the ARRAY type from a text file into the table using a Stream Load job.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "column_separator:|" \
-H "columns:typ_id,name,arr" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading map data type

When the imported data contains a map type, as in the following example:

```
[
{"user_id":1,"namemap":{"Emily":101,"age":25}},
{"user_id":2,"namemap":{"Benjamin":102,"age":35}},
{"user_id":3,"namemap":{"Olivia":103,"age":28}},
{"user_id":4,"namemap":{"Alexander":104,"age":60}},
{"user_id":5,"namemap":{"Ava":105,"age":17}},
{"user_id":6,"namemap":{"William":106,"age":69}},
{"user_id":7,"namemap":{"Sophia":107,"age":32}},
{"user_id":8,"namemap":{"James":108,"age":64}},
{"user_id":9,"namemap":{"Emma":109,"age":37}},
{"user_id":10,"namemap":{"Liam":110,"age":64}}
]
```

Load data into the following table structure:

```
CREATE TABLE testdb.test_streamload(
 user_id BIGINT NOT NULL COMMENT "ID",
 namemap Map<STRING, INT> NULL COMMENT "Name"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

You can directly load the map type from a text file into the table using a Stream Load task.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "format: json" \
-H "strip_outer_array:true" \
-T streamload_example.json \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading bitmap data type

During the import process, when encountering Bitmap type data, you can use `to_bitmap` to convert the data into Bitmap, or use the `bitmap_empty` function to fill the Bitmap.

For example, with the following data:

```
1|koga|17723
2|nijg|146285
3|lojn|347890
4|lofn|489871
5|jfin|545679
6|kon|676724
7|nhga|767689
8|nfubg|879878
9|huang|969798
10|buag|97997
```

Load data into the following table containing the Bitmap type:

```
CREATE TABLE testdb.test_streamload(
 typ_id BIGINT NULL COMMENT "ID",
 hou VARCHAR(10) NULL COMMENT "one",
 arr BITMAP BITMAP_UNION NOT NULL COMMENT "two"
)
AGGREGATE KEY(typ_id,hou)
DISTRIBUTED BY HASH(typ_id,hou) BUCKETS 10;
```

And use `to_bitmap` to convert the data into the Bitmap type.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "Expect:100-continue" \
-H "columns:typ_id,hou,arr,arr=to_bitmap(arr)" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Loading HyperLogLog data type

You can use the `hll_hash` function to convert data into the hll type, as in the following example:

```
1001|koga
1002|nijg
1003|lojn
1004|lofn
1005|jfin
1006|kon
1007|nhga
1008|nfubg
1009|huang
1010|buag
```

Load data into the following table:

```
CREATE TABLE testdb.test_streamload(
 typ_id BIGINT NULL COMMENT "ID",
 typ_name VARCHAR(10) NULL COMMENT "NAME",
 pv hll hll_union NOT NULL COMMENT "hll"
)
AGGREGATE KEY(typ_id,typ_name)
DISTRIBUTED BY HASH(typ_id) BUCKETS 10;
```

And use the `hll_hash` command for import.

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "column_separator:|" \
-H "columns:typ_id,typ_name,pv=hll_hash(typ_id)" \
-T streamload_example.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_streamload/_stream_load
```

## Column mapping, derived columns, and filtering

Doris supports a very rich set of column transformations and filtering operations in load statements. Supports most built-in functions. For how to use this feature correctly, please refer to the [Data Transformation](#)

documentation.

### **Enable strict mode import**

The `strict_mode` attribute is used to set whether the import task runs in strict mode. This attribute affects the results of column mapping, transformation, and filtering, and it also controls the behavior of partial column updates. For specific instructions on strict mode, please refer to the [Handling Messy Data](#) documentation.

### **Perform partial column updates/flexible partial update during import**

For how to express partial column updates during import, please refer to the Data Manipulation/Data Update documentation.

# Broker Load

---

Broker Load is initiated from the MySQL API. Doris will actively pull the data from the source based on the information in the LOAD statement. Broker Load is an asynchronous import method. The progress and result of Broker Load tasks can be viewed by the SHOW LOAD statement.

Broker Load is suitable for scenarios where the source data is stored in remote storage systems, such as HDFS, and the data volume is relatively large.

Direct reads from HDFS or S3 can also be imported through HDFS TVF or S3 TVF in the [Lakehouse/TVF](#). The current “Insert Into” based on TVF is a synchronous import, while Broker Load is an asynchronous import method.

In early versions of Doris, both S3 Load and HDFS Load were implemented by connecting to specific Broker processes using WITH BROKER. In newer versions, S3 Load and HDFS Load have been optimized as the most commonly used import methods, and they no longer depend on an additional Broker process, though they still use syntax similar to Broker Load. Due to historical reasons and the similarity in syntax, S3 Load, HDFS Load, and Broker Load are collectively referred to as Broker Load.

## Limitations

Supported data sources:

- S3 protocol
- HDFS protocol
- Custom protocol (require broker process)

Supported data types:

- CSV
- JSON
- PARQUET
- ORC

Supported compress types:

- PLAIN
- GZ
- LZO
- BZ2
- LZ4FRAME
- DEFLATE
- LZOP
- LZ4BLOCK
- SNAPPYBLOCK
- ZLIB
- ZSTD

## Basic Principles

After a user submits an import task, the Frontend (FE) generates a corresponding plan. Based on the current number of Backend (BE) nodes and the size of the file, the plan is distributed to multiple BE nodes for execution, with each BE node handling a portion of the import data.

During execution, the BE nodes pull data from the Broker, perform necessary transformations, and then import the data into the system. Once all BE nodes have completed the import, the FE makes the final determination on whether the import was successful.

### Broker Load

As seen in the diagram, BE nodes rely on Broker processes to read data from corresponding remote storage systems. The introduction of Broker processes primarily aims to accommodate different remote storage systems. Users can develop their own Broker processes according to established standards. These Broker processes, which can be developed using Java, offer better compatibility with various storage systems in the big data ecosystem. The separation of Broker processes from BE nodes ensures error isolation between the two, enhancing the stability of the BE.

Currently, BE nodes have built-in support for HDFS and S3 Brokers. Therefore, when importing data from HDFS or S3, there is no need to additionally start a Broker process. However, if a customized Broker implementation is required, the corresponding Broker process needs to be deployed.

## Quick start

This section shows a demo for S3 Load. For the specific syntax for usage, please refer to [BROKER LOAD](#) in the SQL manual.

### Prerequisite check

1. Grant privileges on the table

Broker Load requires INSERT privileges on the target table. If there are no INSERT privileges, it can be granted to the user through the [GRANT](#) command.

## 2. S3 authentication and connection info

Here, we mainly introduce how to import data stored in AWS S3. For importing data from other object storage systems that support the S3 protocol, you can refer to the steps for AWS S3.

- AK and SK: First, you need to find or regenerate your AWS Access Keys. You can find instructions on how to generate them in the AWS console under My Security Credentials.
- REGION and ENDPOINT: The REGION can be selected when creating a bucket or viewed in the bucket list. The S3 ENDPOINT for each REGION can be found in the [AWS documentation](#).

## Create load job

1. Create a CSV file brokerload\_example.csv. The file is stored on S3 and its content is as follows:

```
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

2. Create Doris table for the load

Create the imported table in Doris. The SQL statement is as follows:

```
CREATE TABLE testdb.test_brokerload(
 user_id BIGINT NOT NULL COMMENT "user id",
 name VARCHAR(20) COMMENT "name",
 age INT COMMENT "age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

3. Use Broker Load to import data from S3. The bucket name and S3 authentication information should be filled in according to the actual situation:

```
LOAD LABEL broker_load_2022_04_01
(
 DATA INFILE("s3://your_bucket_name/brokerload_example.csv")
 INTO TABLE test_brokerload
 COLUMNS TERMINATED BY ","
 FORMAT AS "CSV"
 (user_id, name, age)
)
WITH S3
(
 "provider" = "S3",
 "AWS_ENDPOINT" = "https://s3.us-west-2.amazonaws.com",
```

```

 "AWS_ACCESS_KEY" = "<your-ak>",
 "AWS_SECRET_KEY" = "<your-sk>",
 "AWS_REGION" = "us-west-2",
 "compress_type" = "PLAIN"
)
PROPERTIES
(
 "timeout" = "3600"
);

```

The provider specifies the vendor of the S3 Service. Supported S3 Provider list:

- “S3” (AWS, Amazon Web Services)
- “AZURE” (Microsoft Azure)
- “GCP” (GCP, Google Cloud Platform)
- “OSS” (Alibaba Cloud)
- “COS” (Tencent Cloud)
- “OBS” (Huawei Cloud)
- “BOS” (Baidu Cloud)

If your service is not in the list (such as MinIO), you can try using “S3” (AWS compatible mode)

## Checking import status

Broker Load is an asynchronous import method, and the specific import results can be viewed through the [SHOW LOAD](#) command.

```

mysql> show load order by createtime desc limit 1\G;
***** 1. row *****
 JobId: 41326624
 Label: broker_load_2022_04_01
 State: FINISHED
 Progress: ETL:100%; LOAD:100%
 Type: BROKER
 EtlInfo: unselected.rows=0; dpp.abnorm.ALL=0; dpp.norm.ALL=27
 TaskInfo: cluster:N/A; timeout(s):1200; max_filter_ratio:0.1
 ErrorMsg: NULL
 CreateTime: 2022-04-01 18:59:06
 EtlStartTime: 2022-04-01 18:59:11
 EtlFinishTime: 2022-04-01 18:59:11
 LoadStartTime: 2022-04-01 18:59:11
 LoadFinishTime: 2022-04-01 18:59:11
 URL: NULL
 JobDetails: {"Unfinished backends":{"5072bde59b74b65-8d2c0ee5b029adc0":
[]},"ScannedRows":27,"TaskNumber":1,"All backends":{"5072bde59b74b65-8d2c0ee5b029adc0":
[36728051]},"FileName":1,"FileSize":5540}
1 row in set (0.01 sec)

```

## Cancelling an Import

When the status of a Broker Load job is not CANCELLED or FINISHED, it can be manually cancelled by the user. To cancel, the user needs to specify the label of the import task to be cancelled. The syntax for the cancel import command can be viewed by executing [CANCEL LOAD](#).

For example: To cancel the import job with the label “broker\_load\_2022\_04\_01” on the DEMO database.

```
CANCEL LOAD FROM demo WHERE LABEL = "broker_load_2022_04_01";
```

## Reference Manual

### SQL syntax for broker load

```
LOAD LABEL load_label
(
 data_desc1[, data_desc2, ...]
 [format_properties]
)
WITH [S3|HDFS|BROKER broker_name]
[broker_properties]
[load_properties]
[COMMENT "comments"];
```

The WITH clause specifies how to access the storage system, and `broker_properties` is the configuration parameter for the access method

- S3: Storage system using the S3 protocol
- HDFS: Storage system using the HDFS protocol
- BROKER `broker_name`: Storage system using other protocols. You can view the currently available `broker_name` list through `SHOW BROKER`. For more information, see “Other Broker Import” in the Common Issues section.

### Related Configurations

#### Load Properties

Property Name	Type	Default Value	Description
“timeout”	Long	14400	Used to specify the timeout for the import in seconds. The configurable range is from 1 second to 259200 seconds.
“max_filter_ratio”	Float	0.0	Used to specify the maximum tolerable ratio of filterable (irregular or otherwise problematic) data, which defaults to zero tolerance. The value range is 0 to 1. If the error rate of the imported data exceeds this value, the import will fail. Irregular data does not include rows filtered out by the where condition.
“strict_mode”	Boolean	false	Used to specify whether to enable strict mode for this import.

Property Name	Type	Default Value	Description
"partial_columns"	Boolean	false	Used to specify whether to enable partial column update, the default value is false, this parameter is only available for Unique Key + Merge on Write tables.
"timezone"	String	"Asia/Shanghai"	Used to specify the timezone to be used for this import. This parameter affects the results of all timezone-related functions involved in the import.
"load_parallelism"	Integer	8	Limits the maximum parallel instances on each backend.
"send_batch_parallelism"	Integer	1	The parallelism for sink node to send data, when memtable_on_sink_node is disabled.
"load_to_single_tablet"	Boolean	"false"	Used to specify whether to load data only to a single tablet corresponding to the partition. This parameter is only available when loading to an OLAP table with random bucketing.
"priority"	oneof "HIGH", "NORMAL", "LOW"	"NORMAL"	The priority of the task.

## Format Properties

Property Name	Type	Default Value	Description
skip_lines	Integer	0	Number of lines to skip at the start of a CSV file. Ignored if using csv_with_names or csv_with_names_and_types.
trim_double_quotes	Boolean	false	If true, trims outermost double quotes from each field.
enclose	String	""	Enclosure character for fields containing delimiters or newlines. E.g., if delimiter is , and encloser is ', then 'b,c' is parsed as one field.

Property Name	Type	Default Value	Description
escape	String	""	Escape character to include enclosure characters in field content. E.g., 'b,\ 'c' keeps 'b, 'c' as one field when ' is the enclosure and \ is the escape.

Note: Format properties define how to parse the source file (e.g., delimiters, quote handling) and must be set inside the LOAD clause. Load properties control the execution behavior (e.g., timeout, retries) and must be set outside, in the outer PROPERTIES block.

```
LOAD LABEL s3_load_example (
 DATA INFILE("s3://bucket/path/file.csv")
 INTO TABLE users
 COLUMNS TERMINATED BY ","
 FORMAT AS "CSV"
 (user_id, name, age)
 PROPERTIES (
 "trim_double_quotes" = "true" -- format property
)
)
WITH S3 (
 ...
)
PROPERTIES (
 "timeout" = "3600" -- load property
);
```

## fe.conf

The following configurations belong to the system-level settings for Broker load, which affect all Broker load import tasks. These configurations can be adjusted by modifying the `fe.conf` file.

Session Variable	Type	Default Value	Description
min_bytes_per_broker_scanner	Long	67108864 (64 MB)	The minimum amount of data processed by a single BE in a Broker Load job, in bytes.
max_bytes_per_broker_scanner	Long	536870912000 (500 GB)	The maximum amount of data processed by a single BE in a Broker Load job, in bytes. Usually, the maximum amount of data supported by an import job is <code>max_bytes_per_broker_scanner * number of BE nodes</code> . If you need to import a larger amount of data, you need to adjust the size of the <code>max_bytes_per_broker_scanner</code> parameter appropriately.
max_broker_concurrency	Integer	10	Limits the maximum number of concurrent imports for a job.

Session Variable	Type	Default Value	Description
default_load_parallelism	Integer	8	Maximum number of concurrent instances per BE node
broker_load_default_timeout_sec	14400	Default timeout for Broker Load import, in seconds.	

Note: The `min_bytes_per_broker_scanner`, the `max_broker_concurrency`, the size of the source file and the number of BEs in the current cluster jointly determine the number of concurrent execution instances for this load.

```
Import Concurrency = Math.min(Source File Size / min_bytes_per_broker_scanner, max_broker_concurrency,
Current Number of BE Nodes * load_parallelism)
Processing Volume per BE for this Import = Source File Size / Import Concurrency
```

## session variables

Session Variable	Type	Default	Description
time_zone	String	"Asia/Shanghai"	Default time zone, which will affect the results of time zone related functions in import.
send_batch_parallelism	Integer	1	The concurrency of the sink node sending data, which takes effect only when <code>enable_memtable_on_sink_node</code> is set to false.

## Common Issues

### Common Errors

#### 1. Import Error: Scan bytes per broker scanner exceed limit:xxx

Please refer to the best practices section in the documentation and modify the FE configuration items `max_bytes_per_broker_scanner` and `max_broker_concurrency`.

#### 2. Import Error: : failed to send batch or TabletWriter add batch with unknown id

Appropriately adjust the `query_timeout` and `streaming_load_rpc_max_alive_time_sec` settings.

#### 3. Import Error: LOAD\_RUN\_FAIL; msg:Invalid Column Name:xxx

For PARQUET or ORC format data, the column names in the file header must match the column names in the Doris table. For example:

```
(tmp_c1,tmp_c2)
SET
(
 id=tmp_c2,
 name=tmp_c1
)
```

This represents fetching columns named (tmp\_c1, tmp\_c2) in the parquet or orc file and mapping them to the (id, name) columns in the Doris table. If no set is specified, the columns in the file header will be used for mapping.

#### Note

If ORC files are generated directly using certain Hive versions, the column headers in the ORC file may not be the Hive metadata, but (\_col0, \_col1, \_col2, ...), which may lead to the Invalid Column Name error. In this case, mapping using SET is necessary.

#### 5. Import Error: Failed to get S3 FileSystem for bucket is null/empty

The bucket information is incorrect or does not exist. Or the bucket format is not supported. When creating a bucket name with an underscore using GCS, such as s3://gs\_bucket/load\_tbl, the S3 Client may report an error when accessing GCS. It is recommended not to use underscores when creating buckets.

#### 6. Import Timeout

The default timeout for imports is 4 hours. If a timeout occurs, it is not recommended to directly increase the maximum import timeout to solve the problem. If the single import time exceeds the default import timeout of 4 hours, it is best to split the file to be imported and perform multiple imports to solve the problem. Setting an excessively long timeout time can lead to high costs for retrying failed imports.

You can calculate the expected maximum import file data volume for the Doris cluster using the following formula:

Expected Maximum Import File Data Volume = 14400s \* 10M/s \* Number of BEs

For example, if the cluster has 10 BEs:

Expected Maximum Import File Data Volume = 14400s \* 10M/s \* 10 = 1440000M ≈ 1440G

#### Note

In general, user environments may not reach speeds of 10M/s, so it is recommended to split files exceeding 500G before importing.

#### S3 Load URL style

- The S3 SDK defaults to using the virtual-hosted style method for accessing objects. However, some object storage systems may not have enabled or supported the virtual-hosted style access. In such cases, we can add the use\_path\_style parameter to force the use of the path style method:

```
WITH S3
(
 "AWS_ENDPOINT" = "AWS_ENDPOINT",
 "AWS_ACCESS_KEY" = "AWS_ACCESS_KEY",
 "AWS_SECRET_KEY"="AWS_SECRET_KEY",
 "AWS_REGION" = "AWS_REGION",
```

```
)
 "use_path_style" = "true"
```

### S3 Load temporary credentials

- Support for accessing all object storage systems that support the S3 protocol using temporary credentials (TOKEN) is available. The usage is as follows:

```
WITH S3
(
 "AWS_ENDPOINT" = "AWS_ENDPOINT",
 "AWS_ACCESS_KEY" = "AWS_TEMP_ACCESS_KEY",
 "AWS_SECRET_KEY" = "AWS_TEMP_SECRET_KEY",
 "AWS_TOKEN" = "AWS_TEMP_TOKEN",
 "AWS_REGION" = "AWS_REGION"
)
```

### HDFS Simple Authentication

Simple authentication refers to the configuration of Hadoop where `hadoop.security.authentication` is set to "simple".

```
(
 "username" = "user",
 "password" = ""
);
```

The username should be configured as the user to be accessed, and the password can be left blank.

### HDFS Kerberos Authentication

This authentication method requires the following information:

- **hadoop.security.authentication:** Specifies the authentication method as Kerberos.
- **hadoop.kerberos.principal:** Specifies the Kerberos principal.
- **hadoop.kerberos.keytab:** Specifies the file path of the Kerberos keytab. The file must be an absolute path on the server where the Broker process is located and must be accessible by the Broker process.
- **kerberos\_keytab\_content:** Specifies the content of the Kerberos keytab file after being encoded in base64. This can be used as an alternative to the `kerberos_keytab` configuration.

Example configuration:

```
(
 "hadoop.security.authentication" = "kerberos",
 "hadoop.kerberos.principal" = "doris@YOUR.COM",
 "hadoop.kerberos.keytab" = "/home/doris/my.keytab"
)
(
 "hadoop.security.authentication" = "kerberos",
 "hadoop.kerberos.principal" = "doris@YOUR.COM",
```

```
"kerberos_keytab_content" = "ASDOWHDLAWIDJHWLDKSALDJSDIWALD"
)
```

To use Kerberos authentication, the [krb5.conf \(opens new window\)](#) file is required. The krb5.conf file contains Kerberos configuration information. Typically, the krb5.conf file should be installed in the /etc directory. You can override the default location by setting the KRB5\_CONFIG environment variable. An example of the krb5.conf file content is as follows:

```
[libdefaults]
 default_realm = DORIS.HADOOP
 default_tkt_enctypes = des3-hmac-sha1 des-cbc-crc
 default_tgs_enctypes = des3-hmac-sha1 des-cbc-crc
 dns_lookup_kdc = true
 dns_lookup_realm = false

[realms]
 DORIS.HADOOP = {
 kdc = kerberos-doris.hadoop.service:7005
 }
```

## HDFS HA Mode

This configuration is used to access HDFS clusters deployed in HA (High Availability) mode.

- **dfs.nameservices:** Specifies the name of the HDFS service, which can be customized. For example: "dfs.nameservices" = "my\_ha".
- **dfs.ha.namenodes.xxx:** Customizes the names of the namenodes, with multiple names separated by commas. Here, xxx represents the custom name specified in dfs.nameservices. For example: "dfs.ha.namenodes.my\_ha" = "my\_nn".
- **dfs.namenode.rpc-address.xxx.nn:** Specifies the RPC address information for the namenode. In this context, nn represents the namenode name configured in dfs.ha.namenodes.xxx. For example: "dfs.namenode.rpc-address.my\_ha.my\_nn" = "host:port".
- **dfs.client.failover.proxy.provider.[nameservice ID]:** Specifies the provider for client connections to the namenode. The default is org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider.

An example configuration is as follows:

```
(
 "fs.defaultFS" = "hdfs://my_ha",
 "dfs.nameservices" = "my_ha",
 "dfs.ha.namenodes.my_ha" = "my_namenode1, my_namenode2",
 "dfs.namenode.rpc-address.my_ha.my_namenode1" = "nn1_host:rpc_port",
 "dfs.namenode.rpc-address.my_ha.my_namenode2" = "nn2_host:rpc_port",
 "dfs.client.failover.proxy.provider.my_ha" =
 "org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
)
```

HA mode can be combined with the previous two authentication methods for cluster access. For example, accessing HA HDFS through simple authentication:

```
(
 "username"="user",
 "password"="passwd",
 "fs.defaultFS" = "hdfs://my_ha",
 "dfs.nameservices" = "my_ha",
 "dfs.ha.namenodes.my_ha" = "my_namenode1, my_namenode2",
 "dfs.namenode.rpc-address.my_ha.my_namenode1" = "nn1_host:rpc_port",
 "dfs.namenode.rpc-address.my_ha.my_namenode2" = "nn2_host:rpc_port",
 "dfs.client.failover.proxy.provider.my_ha" =
"org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
)
```

## Load with other brokers

The Broker for other remote storage systems is an optional process in the Doris cluster, primarily used to support Doris in reading and writing files and directories on remote storage. Currently, Doris provides Broker implementations for various remote storage systems. In earlier versions, different object storage Brokers were also available, but now it is recommended to use the WITH S3 method to import data from object storage, and the WITH BROKER method is no longer recommended.

- Tencent Cloud CHDFS
- Tencent Cloud GFS
- JuiceFS

The Broker provides services through an RPC service port and operates as a stateless Java process. Its primary responsibility is to encapsulate POSIX-like file operations for remote storage, such as open, pread, pwrite, and more. Additionally, the Broker does not keep track of any other information, which means that all the connection details, file information, and permission details related to the remote storage must be passed to the Broker process through parameters during RPC calls. This ensures that the Broker can correctly read and write files.

The Broker serves solely as a data pathway and does not involve any computational tasks, thus requiring minimal memory usage. Typically, a Doris system would deploy one or more Broker processes. Furthermore, Brokers of the same type are grouped together and assigned a unique name (Broker name).

This section primarily focuses on the parameters required by the Broker when accessing different remote storage systems, such as connection information, authentication details, and more. Understanding and correctly configuring these parameters is crucial for successful and secure data exchange between Doris and the remote storage systems.

## Broker Information

The information of the Broker consists of two parts: the name (Broker name) and the authentication information. The usual syntax format is as follows:

```
WITH BROKER "broker_name"
(
 "username" = "xxx",
 "password" = "yyy",
 "other_prop" = "prop_value",
 ...
);
```

## Broker Name

Typically, users need to specify an existing Broker Name through the `WITH BROKER "broker_name"` clause in the operation command. The Broker Name is a name designated by the user when adding a Broker process through the `ALTER SYSTEM ADD BROKER` command. One name usually corresponds to one or more Broker processes. Doris will select an available Broker process based on the name. Users can view the Brokers that currently exist in the cluster through the `SHOW BROKER` command.

### Note

The Broker Name is merely a user-defined name and does not represent the type of Broker.

**Authentication Information** Different Broker types and access methods require different authentication information. The authentication information is usually provided in the Property Map in a Key-Value format after `WITH BROKER "broker_name"`.

## Broker Load examples

### Importing TXT Files from HDFS

```
LOAD LABEL demo.label_20220402
(
 DATA INFILE("hdfs://host:port/tmp/test_hdfs.txt")
 INTO TABLE `load_hdfs_file_test`
 COLUMNS TERMINATED BY "\t"
 (id,age,name)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
)
PROPERTIES
(
 "timeout"="1200",
 "max_filter_ratio"="0.1"
);
```

### HDFS requires the configuration of NameNode HA (High Availability)

```
LOAD LABEL demo.label_20220402
(
 DATA INFILE("hdfs://hafs/tmp/test_hdfs.txt")
 INTO TABLE `load_hdfs_file_test`
 COLUMNS TERMINATED BY "\t"
 (id,age,name)
)
with HDFS
(
 "hadoop.username" = "user",
 "fs.defaultFS"="hdfs://hafs",
 "dfs.nameservices" = "hafs",
 "dfs.ha.namenodes.hafs" = "my_namenode1, my_namenode2",
```

```

 "dfs.namenode.rpc-address.hdfs.my_namenode1" = "nn1_host:rpc_port",
 "dfs.namenode.rpc-address.hdfs.my_namenode2" = "nn2_host:rpc_port",
 "dfs.client.failover.proxy.provider.hdfs" =
"org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
)
PROPERTIES
(
 "timeout"="1200",
 "max_filter_ratio"="0.1"
);

```

## Importing data from HDFS using wildcards to match two batches of files and importing them into two separate tables

```

LOAD LABEL example_db.label2
(
 DATA INFILE("hdfs://host:port/input/file-10*")
 INTO TABLE `my_table1`
 PARTITION (p1)
 COLUMNS TERMINATED BY ","
 (k1, tmp_k2, tmp_k3)
 SET (
 k2 = tmp_k2 + 1,
 k3 = tmp_k3 + 1
),
 DATA INFILE("hdfs://host:port/input/file-20*")
 INTO TABLE `my_table2`
 COLUMNS TERMINATED BY ","
 (k1, k2, k3)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);

```

To import two batches of files matching the wildcards `file-10*` and `file-20*` from HDFS and load them into two separate tables `my_table1` and `my_table2`. In this case, `my_table1` specifies that the data should be imported into partition `p1`, and the values in the second and third columns of the source files should be incremented by 1 before being imported.

## Import a batch of data from HDFS using wildcards

```

LOAD LABEL example_db.label3
(
 DATA INFILE("hdfs://host:port/user/doris/data/*/*")
 INTO TABLE `my_table`
 COLUMNS TERMINATED BY "\\x01"
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);

```

To specify the delimiter as the commonly used default delimiter for Hive, which is `,`, and to use the wildcard character `*` to refer to all files in all directories under the data directory.

## Import Parquet format data and specify the FORMAT as parquet

```
LOAD LABEL example_db.label4
(
 DATA INFILE("hdfs://host:port/input/file")
 INTO TABLE `my_table`
 FORMAT AS "parquet"
 (k1, k2, k3)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);
```

The default method is to determine by file extension.

## Import the data and extract the partition field from the file path

```
LOAD LABEL example_db.label5
(
 DATA INFILE("hdfs://host:port/input/city=beijing/*/*")
 INTO TABLE `my_table`
 FORMAT AS "csv"
 (k1, k2, k3)
 COLUMNS FROM PATH AS (city, utc_date)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);
```

The columns in the my\_table are k1, k2, k3, city, and utc\_date.

The directory hdfs://hdfs\_host:hdfs\_port/user/doris/data/input/dir/city=beijing contains the following files:

```
hdfs://hdfs_host:hdfs_port/input/city=beijing/utc_date=2020-10-01/0000.csv
hdfs://hdfs_host:hdfs_port/input/city=beijing/utc_date=2020-10-02/0000.csv
hdfs://hdfs_host:hdfs_port/input/city=tianji/utc_date=2020-10-03/0000.csv
hdfs://hdfs_host:hdfs_port/input/city=tianji/utc_date=2020-10-04/0000.csv
```

The file only contains three columns of data:k1,k2, and k3. The other two columns,city and utc\_date, will be extracted from the file path.

## Filter the imported data

```
LOAD LABEL example_db.label6
(
 DATA INFILE("hdfs://host:port/input/file")
 INTO TABLE `my_table`
 (k1, k2, k3)
 SET (
 k2 = k2 + 1
```

```

)
 PRECEDING FILTER k1 = 1
 WHERE k1 > k2
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);

```

Only the rows where  $k1 = 1$  in the original data and  $k1 > k2$  after transformation will be imported.

### Import data and extract the time partition field from the file path.

```

LOAD LABEL example_db.label7
(
 DATA INFILE("hdfs://host:port/user/data/*/test.txt")
 INTO TABLE `tbl12`
 COLUMNS TERMINATED BY ","
 (k2,k3)
 COLUMNS FROM PATH AS (data_time)
 SET (
 data_time=str_to_date(data_time, '%Y-%m-%d %H%3A%i%3A%S')
)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username" = "user"
);

```

#### Tip

The time contains “%3A”. In HDFS paths, colons “.” are not allowed, so all colons are replaced with “%3A”.

There are the following files under the path:

```

/user/data/data_time=2020-02-17 00%3A00%3A00/test.txt
/user/data/data_time=2020-02-18 00%3A00%3A00/test.txt

```

The table structure is as follows:

```

CREATE TABLE IF NOT EXISTS tbl12 (
 data_time DATETIME,
 k2 INT,
 k3 INT
) DISTRIBUTED BY HASH(data_time) BUCKETS 10
PROPERTIES (
 "replication_num" = "3"
);

```

## Use Merge mode for import

```
LOAD LABEL example_db.label8
(
 MERGE DATA INFILE("hdfs://host:port/input/file")
 INTO TABLE `my_table`
 (k1, k2, k3, v2, v1)
 DELETE ON v2 > 100
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username"="user"
)
PROPERTIES
(
 "timeout" = "3600",
 "max_filter_ratio" = "0.1"
);
```

To use Merge mode for import, the “my\_table” must be a Unique Key table. When the value of the “v2” column in the imported data is greater than 100, that row will be considered a deletion row. The timeout for the import task is 3600 seconds, and an error rate of up to 10% is allowed.

## Specify the “source\_sequence” column during import to ensure the order of replacements.

```
LOAD LABEL example_db.label9
(
 DATA INFILE("hdfs://host:port/input/file")
 INTO TABLE `my_table`
 COLUMNS TERMINATED BY ","
 (k1,k2,source_sequence,v1,v2)
 ORDER BY source_sequence
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username"="user"
);
```

The “my\_table” must be a Unique Key model table and have a specified Sequence column. The data will maintain its order based on the values in the “source\_sequence” column in the source data.

## Import the specified file format as json, and specify the json\_root and jsonpaths accordingly.

```
LOAD LABEL example_db.label10
(
 DATA INFILE("hdfs://host:port/input/file.json")
 INTO TABLE `my_table`
 FORMAT AS "json"
 PROPERTIES(
 "json_root" = "$.item",
 "jsonpaths" = "[\"$.id\", \"$.city\", \"$.code\"]"
)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
```

```
"hadoop.username"="user"
);
```

The jsonpaths can also be used in conjunction with the column list and SET (column\_mapping) :

```
LOAD LABEL example_db.label10
(
 DATA INFILE("hdfs://host:port/input/file.json")
 INTO TABLE `my_table`
 FORMAT AS "json"
 (id, code, city)
 SET (id = id * 10)
 PROPERTIES(
 "json_root" = "$.item",
 "jsonpaths" = "[\"$.id\", \"$.city\", \"$.code\"]"
)
)
with HDFS
(
 "fs.defaultFS"="hdfs://host:port",
 "hadoop.username"="user"
);
```

### Note

If you need to load the JSON object at the root node of a JSON file, the jsonpaths should be specified as \$., e.g., `PROPERTIES("jsonpaths"="\$.")`

## Load from other brokers

- Alibaba Cloud OSS

```
(
 "fs.oss.accessKeyId" = "",
 "fs.oss.accessKeySecret" = "",
 "fs.oss.endpoint" = ""
)
```

- JuiceFS

```
(
 "fs.defaultFS" = "jfs://xxx/",
 "fs.jfs.impl" = "io.juicefs.JuiceFileSystem",
 "fs.AbstractFileSystem.jfs.impl" = "io.juicefs.JuiceFS",
 "juicefs.meta" = "xxx",
 "juicefs.access-log" = "xxx"
)
```

- GCS

When using a Broker to access GCS, the Project ID is required, while other parameters are optional. Please refer to the [GCS Config](#) for all parameter configurations.

```
(
 "fs.gs.project.id" = "Your Project ID",
 "fs.AbstractFileSystem.gs.impl" = "com.google.cloud.hadoop.fs.gcs.GoogleHadoopFS",
 "fs.gs.impl" = "com.google.cloud.hadoop.fs.gcs.GoogleHadoopFileSystem",
)
```

## More Help

For more detailed syntax and best practices for using [Broker Load](#) , please refer to the Broker Load command manual. You can also enter HELP BROKER LOAD in the MySQL client command line to obtain more help information.

# Routine Load

---

Doris can continuously consume data from Kafka Topic through the Routine Load method. After submitting a Routine Load job, Doris will continuously run the load job, generating real-time loading tasks to constantly consume messages from the specified Topic in the Kafka cluster.

Routine Load is a streaming load job that supports Exactly-Once semantics, ensuring that data is neither lost nor duplicated.

## Usage Scenarios

### Supported Data Sources

Routine Load supports consuming data from Kafka clusters.

### Supported Data File Formats

Routine Load supports consuming data in CSV and JSON formats.

When loading CSV format, it is necessary to clearly distinguish between null values and empty strings:

- Null values need to be represented with `\n`. For example, `a, \n, b` indicates that the middle column is a null value.
- Empty strings can be represented by leaving the data field empty. For example, `a, , b` indicates that the middle column is an empty string.

## Usage Limitations

When using Routine Load to consume data from Kafka, there are the following limitations:

- The supported message formats are CSV and JSON text formats. Each message in CSV should be on a separate line, and the line should not end with a newline character.
- By default, it supports Kafka versions 0.10.0.0 and above. If you need to use a Kafka version below 0.10.0.0 (such as 0.9.0, 0.8.2, 0.8.1, 0.8.0), you need to modify the BE configuration by setting the value of `kafka_broker_version_fallback` to the compatible older version, or directly set the value of `property.broker.version.fallback` when creating the Routine Load. However, using an older version may mean that some new features of Routine Load, such as setting the offset of Kafka partitions based on time, may not be available.

## Basic Principles

Routine Load continuously consumes data from Kafka Topics and writes it into Doris.

When a Routine Load job is created in Doris, it generates a resident import job that consists of several import tasks:

- **Load Job:** A Routine Load Job is a resident import job that continuously consumes data from the data source.
- **Load Task:** An import job is broken down into several import tasks for actual consumption, with each task being an independent transaction.

The specific import process of Routine Load is shown in the following diagram:

#### Routine Load

1. The Client submits a request to create a Routine Load job to the FE, and the FE generates a resident import job (Routine Load Job) through the Routine Load Manager.
2. The FE splits the Routine Load Job into several Routine Load Tasks through the Job Scheduler, which are then scheduled by the Task Scheduler and distributed to BE nodes.
3. On the BE, after a Routine Load Task is completed, it submits the transaction to the FE and updates the Job's metadata.
4. After a Routine Load Task is submitted, it continues to generate new Tasks or retries timed-out Tasks.
5. The newly generated Routine Load Tasks continue to be scheduled by the Task Scheduler in a continuous cycle.

#### Auto Resume

To ensure high availability of jobs, an auto-resume mechanism has been introduced. In the event of an unexpected pause, the Routine Load Scheduler thread will attempt to auto-resume the job. For unexpected Kafka outages or other scenarios where the system is unable to function, the auto-resume mechanism ensures that once Kafka is restored, the routine load job can continue running normally without manual intervention.

Situations where auto-resume will not occur:

- The user manually executes the `PAUSE ROUTINE LOAD` command.

- There are issues with data quality.
- Situations where resuming is not possible, such as when a database table is deleted.

Apart from these three situations, other paused jobs will attempt to resume automatically.

## FAQ

Auto-resume may encounter some issues during cluster restarts or upgrades. Before version 2.1.7, there was a high probability that tasks would not automatically resume after being paused due to cluster restarts or upgrades. Since version 2.1.7, the likelihood of tasks not resuming automatically after such events has decreased.

## Quick Start

### Create Job

In Doris, you can create persistent Routine Load tasks using the `CREATE ROUTINE LOAD` command. For detailed syntax, please refer to [CREATE ROUTINE LOAD](#). Routine Load supports consuming data in CSV and JSON formats.

### Loading CSV Data

#### 1. Loading data sample

In Kafka, there is the following sample data:

```
kafka-console-consumer.sh --bootstrap-server localhost:9092 --topic test-routine-load-csv --from-
beginning
1,Emily,25
2,Benjamin,35
3,Olivia,28
4,Alexander,60
5,Ava,17
6,William,69
7,Sophia,32
8,James,64
9,Emma,37
10,Liam,64
```

#### 2. Creating table

In Doris, create the table for loading with the following syntax:

```
CREATE TABLE testdb.test_routineload_tbl(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User Name",
 age INT COMMENT "User Age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

#### 3. Creating the Routine Load job

In Doris, use the CREATE ROUTINE LOAD command to create the load job:

```
CREATE ROUTINE LOAD testdb.example_routine_load_csv ON test_routineload_tbl
COLUMNS TERMINATED BY ",",
COLUMNS(user_id, name, age)
FROM KAFKA(
 "kafka_broker_list" = "192.168.88.62:9092",
 "kafka_topic" = "test-routine-load-csv",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

## Loading JSON Data

### 1. Loading sample data

In Kafka, there is the following sample data:

```
kafka-console-consumer.sh --bootstrap-server localhost:9092 --topic test-routine-load-json --from-
beginning
```

### 2. Creating table

In Doris, create the table for loading with the following syntax:

```
CREATE TABLE testdb.test_routineload_tbl(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User Name",
 age INT COMMENT "User Age"
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

### 3. Creating the Routine Load job

In Doris, use the CREATE ROUTINE LOAD command to create the job:

```
CREATE ROUTINE LOAD testdb.example_routine_load_json ON test_routineload_tbl
COLUMNS(user_id, name, age)
PROPERTIES(
 "format"="json",
 "jsonpaths"=["\"$.user_id\", \"$.name\", \"$.age\"]"
)
FROM KAFKA(
 "kafka_broker_list" = "192.168.88.62:9092"
);
```

#### Note

If you need to load the JSON object at the root node of a JSON file, the jsonpaths should be specified as \$., e.g., `PROPERTIES("jsonpaths"="\$.")`

## Viewing Status

In Doris, you can check the status of Routine Load jobs and tasks using the following methods:

- Load Jobs: Used to view information about load tasks, such as the target table, number of subtasks, load delay status, load configuration, and load results.
- Load Tasks: Used to view the status of individual load tasks, including task ID, transaction status, task status, execution start time, and BE (Backend) node assignment.

### 01 Viewing Running Jobs

You can use the `SHOW ROUTINE LOAD` command to check the status of jobs. The `SHOW ROUTINE LOAD` command provides information about the current job, including the target table, load delay status, load configuration, and error messages.

For example, to view the status of the `testdb.example_routine_load_csv` job, you can run the following command:

```
mysql> SHOW ROUTINE LOAD FOR testdb.example_routine_load\G
***** 1. row *****
 Id: 12025
 Name: example_routine_load
 CreateTime: 2024-01-15 08:12:42
 PauseTime: NULL
 EndTime: NULL
 DbName: default_cluster:testdb
 TableName: test_routineload_tbl
IsMultiTable: false
 State: RUNNING
DataSourceType: KAFKA
CurrentTaskNum: 1
 JobProperties:
{"max_batch_rows":"200000","timezone":"America/New_York","send_batch_parallelism":"1","load_to_single_tablet":
:"false","column_separator":"","","line_delimiter":"\n","current_concurrent_number":"1","delete":"*","partial
_columns":"false","merge_type":"APPEND","exec_mem_limit":"2147483648","strict_mode":"false","jsonpaths":"","m
ax_batch_interval":"10","max_batch_size":"104857600","fuzzy_parse":"false","partitions":"*","columnToColumnEx
pr":"user_id,name,age","whereExpr":"*","desired_concurrent_number":"5","precedingFilter":"*","format":"csv","
max_error_number":"0","max_filter_ratio":"1.0","json_root":"","strip_outer_array":"false","num_as_string":"fa
lse"}
DataSourceProperties: {"topic":"test-topic","currentKafkaPartitions":"0","brokerList":"192.168.88.62:9092"}
 CustomProperties: {"kafka_default_offsets":"OFFSET_BEGINNING","group.id":"example_routine_load_73daf600-
884e-46c0-a02b-4e49fdf3b4dc"}
 Statistic: {"receivedBytes":28,"runningTxns":
[],"errorRows":0,"committedTaskNum":3,"loadedRows":3,"loadRowsRate":0,"abortedTaskNum":0,"errorRowsAfterResum
ed":0,"totalRows":3,"unselectedRows":0,"receivedBytesRate":0,"taskExecuteTimeMs":30069}
 Progress: {"0":"2"}
 Lag: {"0":0}
ReasonOfStateChanged:
 ErrorLogUrls:
 OtherMsg:
 User: root
 Comment:
1 row in set (0.00 sec)
```

### 02 Viewing Running Tasks

You can use the `SHOW ROUTINE LOAD TASK` command to check the status of load tasks. The `SHOW ROUTINE LOAD TASK` command provides information about the individual tasks under a specific load job, including task ID, transaction status, task status, execution start time, and BE ID.

For example, to view the task status of the `example_routine_load_csv` job, you can run the following command:

```
mysql> SHOW ROUTINE LOAD TASK WHERE jobname = 'example_routine_load_csv';
```

TaskId	TxnId	TxnStatus	JobId	CreateTime	ExecuteStartTime
8cf47e6a68ed4da3-8f45b431db50e466	195	PREPARE	12177	2024-01-15 12:20:41	2024-01-15 12:21:01
f2d4525c54074aa2-b6478cf8daeb393	196	PREPARE	12177	2024-01-15 12:20:41	2024-01-15 12:21:01
cb870f1553864250-975279875a25fab6	-1	NULL	12177	2024-01-15 12:20:52	NULL
68771fd8a1824637-90a9dac2a7a0075e	-1	NULL	12177	2024-01-15 12:20:52	NULL
77112dfea5e54b0a-a10eab3d5b19e565	197	PREPARE	12177	2024-01-15 12:21:02	2024-01-15 12:21:02

Pausing Jobs

You can pause an load job using the [PAUSE ROUTINE LOAD](#) command. When a job is paused, it enters the PAUSED state, but the load job is not terminated and can be resumed using the `RESUME ROUTINE LOAD` command.

To pause the `testdb.example_routine_load_csv` load job, you can use the following command:

```
PAUSE ROUTINE LOAD FOR testdb.example_routine_load_csv;
```

Resuming Jobs

You can resume a paused load job using the [RESUME ROUTINE LOAD](#) command.

To resume the `testdb.example_routine_load_csv` job, you can use the following command:

```
RESUME ROUTINE LOAD FOR testdb.example_routine_load_csv;
```

Modifying Jobs

You can modify a created loading job using the [ALTER ROUTINE LOAD](#) command. Before modifying the job, you need to pause it using the `PAUSE ROUTINE LOAD` command, and after making the modifications, you can resume it using the `RESUME ROUTINE LOAD` command.

To modify the `desired_concurrent_number` parameter for the job and update the Kafka topic information, you can use the following command:

```
ALTER ROUTINE LOAD FOR testdb.example_routine_load_csv
PROPERTIES(
 "desired_concurrent_number" = "3"
)
FROM KAFKA(
 "kafka_broker_list" = "192.168.88.60:9092",
 "kafka_topic" = "test-topic"
);
```

## Canceling Jobs

You can stop and delete a Routine Load job using the [STOP ROUTINE LOAD](#) command. Once deleted, the load job cannot be recovered and cannot be viewed using the `SHOW ROUTINE LOAD` command.

To stop and delete the `testdb.example_routine_load_csv` load job, you can use the following command:

```
STOP ROUTINE LOAD FOR testdb.example_routine_load_csv;
```

## Reference Manual

### Load Commands

The syntax for creating a Routine Load persistent load job is as follows:

```
CREATE ROUTINE LOAD [<db_name>.<job_name> [ON <tbl_name>]
[merge_type]
[load_properties]
[job_properties]
FROM KAFKA [data_source_properties]
[COMMENT "<comment>"]
```

The modules for creating a loading job are explained as follows:

Module	Description
db_name	Specifies the name of the database for creating the loading task.
job_name	Specifies the name of the created loading job. The job name must be unique within the same database.
tbl_name	Specifies the name of the table to be loaded. This parameter is optional. If not specified, the dynamic table mode will be used, where Kafka data should contain the table name information.
merge_type	Specifies the data merge type. The default value is APPEND. Possible merge_type options are:
load_properties	Describes the load properties, including:
job_properties	Specifies the general load parameters for Routine Load.
data_source_properties	Describes the properties of Kafka data source.
comment	Describes any additional comments for the loading job.

## Load Parameter Description

### 01 FE Configuration Parameters

Parameter Name	Default Value	Dynamic Configuration	FE Master Exclusive Configuration	Description
max_routine_load_task_concurrent_num	256	Yes	Yes	Limits the maximum number of concurrent subtasks for Routine Load jobs. It is recommended to maintain the default value. If set too high, it may lead to excessive concurrent tasks, consuming cluster resources.
max_routine_load_task_num_per_be	1024	Yes	Yes	The maximum number of concurrent Routine Load tasks allowed per BE. max_routine_load_task_num_per_be should be less than routine_load_thread_pool_size.
max_routine_load_job_num	100	Yes	Yes	Limits the maximum number of Routine Load jobs, including NEED_SCHEDULED, RUNNING, and PAUSE.
max_tolerable_backend_down_num	0	Yes	Yes	If any BE is down, Routine Load cannot automatically recover. Under certain conditions, Doris can reschedule PAUSED tasks to RUNNING state. A value of 0 means that rescheduling is only allowed when all BE nodes are alive.
period_of_auto_resume_min	5 (minutes)	Yes	Yes	The period for automatically resuming Routine Load.

### 02 BE Configuration Parameters

Parameter Name	Default Value	Dynamic Configuration	Description
max_consumer_num_per_group	3	Yes	The maximum number of consumers that can be generated for a subtask to consume data. For Kafka data sources, a consumer may consume one or more Kafka partitions. If a task needs to consume 6 Kafka partitions, it will generate 3 consumers, each consuming 2 partitions. If there are only 2 partitions, it will generate only 2 consumers, each consuming 1 partition.

## Load Configuration Parameters

When creating a Routine Load job, you can specify the load configuration parameters for different modules using the `CREATE ROUTINE LOAD` command.

### tbl\_name Clause

Specifies the name of the table to be loaded. This parameter is optional.

If not specified, the dynamic table mode is used, which requires the data in Kafka to contain the table name information. Currently, only extracting the table name from the Value field of Kafka is supported. The format should be as follows, using JSON as an example: `table_name|{"col1": "val1", "col2": "val2"}`, where `tbl_name` is the table name and `|` is used as the separator between the table name and the table data. The same format applies to CSV data, such as `table_name|val1,val2,val3`. Note that the `table_name` here must

be consistent with the table name in Doris, otherwise the load will fail. Note that dynamic tables do not support the column\_mapping configuration described later.

### merge\_type Clause

The merge\_type module specifies the type of data merging. There are three options for merge\_type:

- APPEND: Append load mode.
- MERGE: Merge load mode. Only applicable to Unique Key models. It needs to be used together with the [DELETE ON] module to mark the Delete Flag column.
- DELETE: All loaded data is data that needs to be deleted.

### load\_properties Clause

The load\_properties module describes the properties of the loaded data using the following syntax:

```
[COLUMNS TERMINATED BY <column_separator>,
[COLUMNS (<column1_name>[, <column2_name>, <column_mapping>, ...]),]
[WHERE <where_expr>],
[PARTITION(<partition1_name>, [<partition2_name>, <partition3_name>, ...]),]
[DELETE ON <delete_expr>],
[ORDER BY <order_by_column1>[, <order_by_column2>, <order_by_column3>, ...]]
```

The specific parameters for each module are as follows:

Submodule	Parameter	Description
COLUMNS TERMINATED BY	<column_separator>	Specifies the column delimiter, defaulting to \t. For example, to specify a comma as the delimiter, use COLUMNS TERMINATED BY ",". When handling empty values, note the following:
COLUMNS	<column_name>	Specifies the corresponding column names. For example, to specify the load columns as (k1, k2, k3), use COLUMNS(k1, k2, k3). The COLUMNS clause can be omitted in the following cases:
	<column_mapping>	During the load process, column mapping can be used to filter and transform columns. For example, if the target column needs to perform a derived calculation based on a column in the data source (e.g., the target column k4 is calculated as k3 + 1 based on the k3 column), you can use COLUMNS(k1, k2, k3, k4 = k3 + 1). For more details, refer to the <a href="#">Data Conversion</a> documentation.
WHERE	<where_expr>	Specifies the condition to filter the loaded data source. For example, to load only data where age > 30, use WHERE age > 30.
PARTITION	<partition_name>	Specifies which partitions in the target table to load. If not specified, it will automatically load into the corresponding partitions. For example, to load partitions p1 and p2 of the target table, use PARTITION(p1, p2).
DELETE ON	<delete_expr>	In the MERGE load mode, using delete_expr to mark which columns need to be deleted. For example, to delete columns where age > 30 during the MERGE process, use DELETE ON age > 30.

Submodule	Parameter	Description
ORDER BY	<order_by_column>	Only effective for Unique Key models. Specifies the Sequence Column in the loaded data to ensure the order of the data. For example, when loading into a Unique Key table and specifying create_time as the Sequence Column, use ORDER BY create_time. For more information on Sequence Columns in Unique Key models, refer to the <a href="#">Data Update/Sequence Columns</a>

## job\_properties Clause

The job\_properties clause is used to specify the properties of a Routine Load job when creating it. The syntax is as follows:

```
PROPERTIES ("<key1>" = "<value1>"[, "<key2>" = "<value2>" ...])
```

Here are the available parameters for the job\_properties clause:

Parameter	Description
desired_concurrent_number	
max_batch_interval	The maximum running time for each subtask, in seconds. Must be greater than 0, with a default value of 60s. max_batch_interval/max_batch_rows/max_batch_size together form the execution threshold for subtasks. If any of these parameters reaches the threshold, the load subtask ends and a new one is generated.
max_batch_rows	The maximum number of rows read by each subtask. Must be greater than or equal to 200,000. The default value is 20,000,000. max_batch_interval/max_batch_rows/max_batch_size together form the execution threshold for subtasks. If any of these parameters reaches the threshold, the load subtask ends and a new one is generated.
max_batch_size	The maximum number of bytes read by each subtask. The unit is bytes, and the range is from 100MB to 10GB. The default value is 1G. max_batch_interval/max_batch_rows/max_batch_size together form the execution threshold for subtasks. If any of these parameters reaches the threshold, the load subtask ends and a new one is generated.
max_error_number	The maximum number of error rows allowed within a sampling window. Must be greater than or equal to 0. The default value is 0, which means no error rows are allowed. The sampling window is max_batch_rows * 10. If the number of error rows within the sampling window exceeds max_error_number, the regular job will be paused and manual intervention is required to check for data quality issues using the <a href="#">SHOW ROUTINE LOAD</a> command and ErrorLogUrls. Rows filtered out by the WHERE condition are not counted as error rows.
strict_mode	Whether to enable strict mode. The default value is disabled. Strict mode applies strict filtering to type conversions during the load process. If enabled, non-null original data that results in a NULL after type conversion will be filtered out. The filtering rules in strict mode are as follows:
timezone	Specifies the time zone used by the load job. The default is to use the session's timezone parameter. This parameter affects the results of all timezone-related functions involved in the load.
format	Specifies the data format for the load. The default is CSV, and JSON format is supported.
jsonpaths	When the data format is JSON, jsonpaths can be used to specify the JSON paths to extract data from nested structures. It is a JSON array of strings, where each string represents a JSON path.

Parameter	Description
json_root	When importing JSON format data, you can specify the root node of the JSON data through json_root. Doris will extract and parse elements from the root node. Default is empty. For example, specify the JSON root node with: "json_root" = "\$.RECORDS"
strip_outer_array	When importing JSON format data, if strip_outer_array is true, it indicates that the JSON data is presented as an array, and each element in the data will be treated as a row. Default value is false. Typically, JSON data in Kafka might be represented as an array with square brackets [] in the outermost layer. In this case, you can specify "strip_outer_array" = "true" to consume Topic data in array mode. For example, the following data will be parsed into two rows: [{"user_id":1,"name":"Emily","age":25}, {"user_id":2,"name":"Benjamin","age":35}]
send_batch_parallelism	Used to set the parallelism of sending batch data. If the parallelism value exceeds the max_send_batch_parallelism_per_job in BE configuration, the coordinating BE will use the value of max_send_batch_parallelism_per_job.
load_to_single_tablet	Supports importing data to only one tablet in the corresponding partition per task. Default value is false. This parameter can only be set when importing data to OLAP tables with random bucketing.
partial_columns	Specifies whether to enable partial column update feature. Default value is false. This parameter can only be set when the table model is Unique and uses Merge on Write. Multi-table streaming does not support this parameter. For details, refer to <a href="#">Partial Column Update</a>
max_filter_ratio	The maximum allowed filter ratio within the sampling window. Must be between 0 and 1 inclusive. Default value is 1.0, indicating any error rows can be tolerated. The sampling window is max_batch_rows * 10. If the ratio of error rows to total rows within the sampling window exceeds max_filter_ratio, the routine job will be suspended and require manual intervention to check data quality issues. Rows filtered by WHERE conditions are not counted as error rows.
enclose	Specifies the enclosing character. When CSV data fields contain line or column separators, a single-byte character can be specified as an enclosing character for protection to prevent accidental truncation. For example, if the column separator is "," and the enclosing character is "'", the data "a,b,c" will have "b,c" parsed as one field.
escape	Specifies the escape character. Used to escape characters in fields that are identical to the enclosing character. For example, if the data is "a,b,c", the enclosing character is "'", and you want "b,c" to be parsed as one field, you need to specify a single-byte escape character, such as "\", and modify the data to "a,b,c".

These parameters can be used to customize the behavior of a Routine Load job according to your specific requirements.

#### 04 data\_source\_properties Clause

When creating a Routine Load job, you can specify the data\_source\_properties clause to specify properties of the Kafka data source. The syntax is as follows:

```
FROM KAFKA ("<key1>" = "<value1>"[, "<key2>" = "<value2>" ...])
```

The available options for the data\_source\_properties clause are as follows:

Parameter	Description
kafka_broker_list	Specifies the connection information for Kafka brokers. The format is <kafka_broker_ip>:<kafka_port>. Multiple brokers are separated by commas. For example, to specify a Broker List with the default port 9092, you can use the following command: "kafka_broker_list" = "<broker1_ip>:9092,<broker2_ip>:9092"
kafka_topic	Specifies the Kafka topic to subscribe to. A load job can only consume one Kafka topic.
kafka_partitions	Specifies the Kafka partitions to subscribe to. If not specified, all partitions are consumed by default.
kafka_offsets	Specifies the starting consumption offset for Kafka partitions. If a timestamp is specified, consumption starts from the nearest offset equal to or greater than that timestamp. The offset can be a specific offset greater than or equal to 0, or it can use the following formats:
property	Specifies custom Kafka parameters. This is equivalent to the “-property” parameter in the Kafka shell. When the value of a parameter is a file, the keyword “FILE:” needs to be added before the value. For creating a file, you can refer to the <a href="#">CREATE FILE</a> command documentation. For more supported custom parameters, you can refer to the client-side configuration options in the official <a href="#">CONFIGURATION</a> documentation of librdkafka. For example: "property.client.id" = "12345", "property.group.id" = "group_id_0", "property.ssl.ca.location" = "FILE:ca.pem"

By configuring the Kafka property parameter in the `data_source_properties`, you can set up security access options. Currently, Doris supports various Kafka security protocols such as plaintext (default), SSL, PLAIN, and Kerberos.

## Load Status

You can check the status of a load job using the `SHOW ROUTINE LOAD` command. The syntax for the command is as follows:

```
SHOW [ALL] ROUTINE LOAD [FOR jobName];
```

For example, executing `SHOW ROUTINE LOAD` will return a result set similar to the following:

```
mysql> SHOW ROUTINE LOAD FOR testdb.example_routine_load\G
***** 1. row *****
 Id: 12025
 Name: example_routine_load
 CreateTime: 2024-01-15 08:12:42
 PauseTime: NULL
 EndTime: NULL
 DbName: default_cluster:testdb
 TableName: test_routineload_tbl
 IsMultiTable: false
 State: RUNNING
 DataSourceType: KAFKA

The columns in the result set provide the following information:

Column Name	Description
Id	The ID of the load job, automatically generated by Doris.
Name	The name of the load job.
CreateTime	The time when the job was created.
PauseTime	The time when the job was last paused.
EndTime	The time when the job ended.
DbName	The name of the associated database.
TableName	The name of the associated table. For multi-table scenarios, it is displayed as "multi-table".
IsMultiTbl	Indicates whether it is a multi-table load.
State	The running state of the job, which can have five values:
DataSourceType	The type of data source, which is KAFKA, in this example.
CurrentTaskNum	The current number of subtasks.
JobProperties	Details of the job configuration.
DataSourceProperties	Details of the data source configuration.
CustomProperties	Custom configuration properties.
Statistic	Statistics of the job's running status.
Progress	The job's progress. For Kafka data sources, it shows the offset consumed for each partition. For example, {"0":"2"} indicates that partition 0 has consumed 2 offsets.
Lag	The lag of the job. For Kafka data sources, it shows the consumption lag for each partition. For example, {"0":10} indicates a consumption lag of 10 for partition 0.
ReasonOfStateChanged	The reason for the state change of jobs.
ErrorLogUrls	The URL(s) to view the filtered low-quality data.
OtherMsg	Other error messages.

## Load example

### Setting the Maximum Error Tolerance

1. Load sample data:

```
1,Benjamin,18
2,Emily,20
3,Alexander,dirty_data
```

2. Create table:

```
CREATE TABLE demo.routine_test01 (
 id INT NOT NULL COMMENT "User ID",
 name VARCHAR(30) NOT NULL COMMENT "Name",
 age INT COMMENT "Age"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job01 ON routine_test01
 COLUMNS TERMINATED BY ","
 PROPERTIES
 (
 "max_filter_ratio"="0.5",
 "max_error_number" = "100",
 "strict_mode" = "true"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad01",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

4. Load result:

```
mysql> select * from routine_test01;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
+-----+-----+-----+
2 rows in set (0.01 sec)
```

### Consuming Data from a Specified Offset

1. Load sample data:

```
1,Benjamin,18
2,Emily,20
```

```
3,Alexander,22
4,Sophia,24
5,William,26
6,Charlotte,28
```

## 2. Create table:

```
CREATE TABLE demo.routine_test02 (
 id INT NOT NULL COMMENT "User ID",
 name VARCHAR(30) NOT NULL COMMENT "Name",
 age INT COMMENT "Age"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

## 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job02 ON routine_test02
 COLUMNS TERMINATED BY ","
 FROM KAFKA
 (
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad02",
 "kafka_partitions" = "0",
 "kafka_offsets" = "3"
);
```

## 4. Load result:

```
mysql> select * from routine_test02;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 4 | Sophia | 24 |
| 5 | William | 26 |
| 6 | Charlotte | 28 |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

# Specifying the Consumer Group's group.id and client.id

## 1. Load sample data:

```
1,Benjamin,18
2,Emily,20
3,Alexander,22
```

## 2. Create table:

```
CREATE TABLE demo.routine_test03 (
 id INT NOT NULL COMMENT "User ID",
 name VARCHAR(30) NOT NULL COMMENT "Name",
 age INT COMMENT "Age"
)
```

```
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job03 ON routine_test03
 COLUMNS TERMINATED BY ","
 FROM KAFKA
 (
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad01",
 "property.group.id" = "kafka_job03",
 "property.client.id" = "kafka_client_03",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

### 4. Load result:

```
mysql> select * from routine_test03;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

## Setting load filtering conditions

### 1. Load sample data:

```
1,Benjamin,18
2,Emily,20
3,Alexander,22
4,Sophia,24
5,William,26
6,Charlotte,28
```

### 2. Create table:

```
CREATE TABLE demo.routine_test04 (
 id INT NOT NULL COMMENT "User ID",
 name VARCHAR(30) NOT NULL COMMENT "Name",
 age INT COMMENT "Age"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job04 ON routine_test04
 COLUMNS TERMINATED BY ",",
 WHERE id >= 3
 FROM KAFKA
```

```
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad04",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> select * from routine_test04;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 4 | Sophia | 24 |
| 5 | William | 26 |
| 6 | Charlotte | 28 |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

## Loading specified partition data

#### 1. Load sample data:

```
1,Benjamin,18,2024-02-04 10:00:00
2,Emily,20,2024-02-05 11:00:00
3,Alexander,22,2024-02-06 12:00:00
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test05 (
 id INT NOT NULL COMMENT "ID",
 name VARCHAR(30) NOT NULL COMMENT "Name",
 age INT COMMENT "Age",
 date DATETIME COMMENT "Date"
)
DUPLICATE KEY(`id`)
PARTITION BY RANGE(`id`)
(PARTITION partition_a VALUES [("0"), ("1")),
PARTITION partition_b VALUES [("1"), ("2")),
PARTITION partition_c VALUES [("2"), ("3")])
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job05 ON routine_test05
 COLUMNS TERMINATED BY ",",
 PARTITION(partition_b)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad05",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> select * from routine_test05;
```

id	name	age	date
1	Benjamin	18	2024-02-04 10:00:00

```
1 rows in set (0.01 sec)
```

## Setting Time Zone for load

### 1. Load sample data:

```
1,Benjamin,18,2024-02-04 10:00:00
2,Emily,20,2024-02-05 11:00:00
3,Alexander,22,2024-02-06 12:00:00
```

### 2. Create table:

```
CREATE TABLE demo.routine_test06 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 date DATETIME COMMENT "date"
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job06 ON routine_test06
 COLUMNS TERMINATED BY ","
 PROPERTIES
 (
 "timezone" = "Asia/Shanghai"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad06",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

### 4. Load result:

```
mysql> select * from routine_test06;
```

id	name	age	date
1	Benjamin	18	2024-02-04 10:00:00
2	Emily	20	2024-02-05 11:00:00
3	Alexander	22	2024-02-06 12:00:00

```
3 rows in set (0.00 sec)
```

## Setting merge\_type

### Specify merge\_type for delete operation

#### 1. Load sample data:

```
3,Alexander,22
5,William,26
```

Table data before load:

```
mysql> SELECT * FROM routine_test07;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
| 4 | Sophia | 24 |
| 5 | William | 26 |
| 6 | Charlotte | 28 |
+-----+-----+-----+
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test07 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age"
)
UNIQUE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job07 ON routine_test07
 WITH DELETE
 COLUMNS TERMINATED BY ","
 FROM KAFKA
 (
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad07",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> SELECT * FROM routine_test07;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 4 | Sophia | 24 |
+-----+-----+-----+
```

6	Charlotte	28
---	-----------	----

## Specify merge\_type for merge operation

### 1. Load sample data:

```
1,xiaoxiaoli,28
2,xiaoxiaowang,30
3,xiaoxiaoliu,32
4,dadali,34
5,dadawang,36
6,dadaliu,38
```

### Table data before load:

```
mysql> SELECT * FROM routine_test08;
+-----+-----+
| id | name | age |
+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
| 4 | Sophia | 24 |
| 5 | William | 26 |
| 6 | Charlotte | 28 |
+-----+-----+
6 rows in set (0.01 sec)
```

### 2. Create table:

```
CREATE TABLE demo.routine_test08 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age"
)
UNIQUE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job08 ON routine_test08
WITH MERGE
COLUMNS TERMINATED BY ",",
DELETE ON id = 2
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad08",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

### 4. Load result:

```
mysql> SELECT * FROM routine_test08;
+-----+-----+
| id | name | age |
+-----+-----+
```

id	name	age
1	xiaoxiaoli	28
3	xiaoxiaoliu	32
4	dadali	34
5	dadawang	36
6	dadaliu	38

5 rows in set (0.00 sec)

## Specifying the sequence column to be merged

### 1. Load sample data:

```
1,xiaoxiaoli,28
2,xiaoxiaowang,30
3,xiaoxiaoliu,32
4,dadali,34
5,dadawang,36
6,dadaliu,38
```

Data in the table before loading:

```
mysql> SELECT * FROM routine_test09;
+----+-----+-----+
| id | name | age |
+----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
| 4 | Sophia | 24 |
| 5 | William | 26 |
| 6 | Charlotte | 28 |
+----+-----+-----+
6 rows in set (0.01 sec)
```

### 2. Create table

```
CREATE TABLE demo.routine_test08 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
)
UNIQUE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "function_column.sequence_col" = "age"
);
```

### 3. Load Command

```
CREATE ROUTINE LOAD demo.kafka_job09 ON routine_test09
 WITH MERGE
 COLUMNS TERMINATED BY ",",
 COLUMNS(id, name, age),
 DELETE ON id = 2,
 ORDER BY age
 PROPERTIES
```

```
(
 "desired_concurrent_number"="1",
 "strict_mode" = "false"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad09",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> SELECT * FROM routine_test09;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | xiaoxiaoli | 28 |
| 3 | xiaoxiaoliu | 32 |
| 4 | dadali | 34 |
| 5 | dadawang | 36 |
| 6 | dadaliu | 38 |
+-----+-----+-----+
5 rows in set (0.00 sec)
```

### Load with column mapping and derived column calculation

#### 1. Load sample data:

```
1,Benjamin,18
2,Emily,20
3,Alexander,22
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test10 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 num INT COMMENT "number"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job10 ON routine_test10
 COLUMNS TERMINATED BY ",",
 COLUMNS(id, name, age, num=age*10)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad10",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> SELECT * FROM routine_test10;
+-----+-----+-----+-----+
| id | name | age | num |
+-----+-----+-----+-----+
| 1 | Benjamin | 18 | 180 |
| 2 | Emily | 20 | 200 |
| 3 | Alexander | 22 | 220 |
+-----+-----+-----+-----+
3 rows in set (0.01 sec)
```

### Load with enclosed data

#### 1. Load sample data:

```
1,"Benjamin",18
2,"Emily",20
3,"Alexander",22
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test11 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 num INT COMMENT "number"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job11 ON routine_test11
 COLUMNS TERMINATED BY ","
 PROPERTIES
 (
 "desired_concurrent_number"="1",
 "enclose" = "\""
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad12",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> SELECT * FROM routine_test11;
+-----+-----+-----+-----+
| id | name | age | num |
+-----+-----+-----+-----+
| 1 | Benjamin | 18 | 180 |
| 2 | Emily | 20 | 200 |
| 3 | Alexander | 22 | 220 |
+-----+-----+-----+-----+
```

```
+-----+-----+-----+-----+
3 rows in set (0.02 sec)
```

## JSON Format Load

### Load JSON format data in simple mode

#### 1. Load sample data:

```
{ "id" : 1, "name" : "Benjamin", "age":18 }
{ "id" : 2, "name" : "Emily", "age":20 }
{ "id" : 3, "name" : "Alexander", "age":22 }
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test12 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job12 ON routine_test12
 PROPERTIES
 (
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad12",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> select * from routine_test12;
+-----+-----+-----+-----+
| id | name | age |
+-----+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
+-----+-----+-----+-----+
3 rows in set (0.02 sec)
```

### Load complex JSON format data in match mode

#### 1. Load sample data

```
{ "name" : "Benjamin", "id" : 1, "num":180 , "age":18 }
{ "name" : "Emily", "id" : 2, "num":200 , "age":20 }
```

```
{ "name" : "Alexander", "id" : 3, "num":220 , "age":22 }
```

## 2. Create table:

```
CREATE TABLE demo.routine_test13 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 num INT COMMENT "num"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

## 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job13 ON routine_test13
 COLUMNS(name, id, num, age)
 PROPERTIES
 (
 "format" = "json",
 "jsonpaths" = "[\"$.name\", \"$.id\", \"$.num\", \"$.age\"]"
)
FROM KAFKA
 (
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad13",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

## 4. Load result:

```
mysql> select * from routine_test13;
+-----+-----+-----+-----+
| id | name | age | num |
+-----+-----+-----+-----+
| 1 | Benjamin | 18 | 180 |
| 2 | Emily | 20 | 200 |
| 3 | Alexander | 22 | 220 |
+-----+-----+-----+-----+
3 rows in set (0.01 sec)
```

## Loading data with specified JSON root node

### 1. Load sample data

```
{"id": 1231, "source" :{ "id" : 1, "name" : "Benjamin", "age":18 }}
{"id": 1232, "source" :{ "id" : 2, "name" : "Emily", "age":20 }}
{"id": 1233, "source" :{ "id" : 3, "name" : "Alexander", "age":22 }}
```

### 2. Create table:

```
CREATE TABLE demo.routine_test14 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age"
)
```

```
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

### 3. Load command

```
CREATE ROUTINE LOAD demo.kafka_job14 ON routine_test14
 PROPERTIES
 (
 "format" = "json",
 "json_root" = "$.source"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad14",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

### 4. Load result

```
mysql> select * from routine_test14;
+-----+-----+-----+
| id | name | age |
+-----+-----+-----+
| 1 | Benjamin | 18 |
| 2 | Emily | 20 |
| 3 | Alexander | 22 |
+-----+-----+-----+
3 rows in set (0.01 sec)
```

## Loading data with column mapping and derived column calculation

### 1. Load sample data:

```
{ "id" : 1, "name" : "Benjamin", "age":18 }
{ "id" : 2, "name" : "Emily", "age":20 }
{ "id" : 3, "name" : "Alexander", "age":22 }
```

### 2. Create table:

```
CREATE TABLE demo.routine_test15 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 num INT COMMENT "num"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job15 ON routine_test15
 COLUMNS(id, name, age, num=age*10)
 PROPERTIES
 (
 "format" = "json",
```

```

)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad15",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);

```

#### 4. Load result:

```

mysql> select * from routine_test15;
+-----+-----+-----+-----+
| id | name | age | num |
+-----+-----+-----+-----+
| 1 | Benjamin | 18 | 180 |
| 2 | Emily | 20 | 200 |
| 3 | Alexander | 22 | 220 |
+-----+-----+-----+-----+
3 rows in set (0.01 sec)

```

## Loading Complex Data Types

### Load Array Data Type

#### 1. Load sample data:

```

{ "id" : 1, "name" : "Benjamin", "age":18, "array":[1,2,3,4,5]}
{ "id" : 2, "name" : "Emily", "age":20, "array":[6,7,8,9,10]}
{ "id" : 3, "name" : "Alexander", "age":22, "array":[11,12,13,14,15]}

```

#### 2. Create table:

```

CREATE TABLE demo.routine_test16
(
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 array ARRAY<int(11)> NULL COMMENT "test array column"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;

```

#### 3. Load command:

```

CREATE ROUTINE LOAD demo.kafka_job16 ON routine_test16
PROPERTIES
(
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad16",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);

```

#### 4. Load result:

```
mysql> select * from routine_test16;
```

id	name	age	array
1	Benjamin	18	[1, 2, 3, 4, 5]
2	Emily	20	[6, 7, 8, 9, 10]
3	Alexander	22	[11, 12, 13, 14, 15]

```
3 rows in set (0.00 sec)
```

### Loading Map Data Type

#### 1. Load sample data:

```
{ "id" : 1, "name" : "Benjamin", "age":18, "map":{"a": 100, "b": 200}}
{ "id" : 2, "name" : "Emily", "age":20, "map":{"c": 300, "d": 400}}
{ "id" : 3, "name" : "Alexander", "age":22, "map":{"e": 500, "f": 600}}
```

#### 2. Create table:

```
CREATE TABLE demo.routine_test17 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 map Map<STRING, INT> NULL COMMENT "test column"
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

#### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job17 ON routine_test17
PROPERTIES
(
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad17",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

#### 4. Load result:

```
mysql> select * from routine_test17;
```

id	name	age	map
1	Benjamin	18	{"a":100, "b":200}
2	Emily	20	{"c":300, "d":400}
3	Alexander	22	{"e":500, "f":600}

```
3 rows in set (0.01 sec)
```

## Loading Bitmap Data Type

### 1. Load sample data

```
{ "id" : 1, "name" : "Benjamin", "age":18, "bitmap_id":243}
{ "id" : 2, "name" : "Emily", "age":20, "bitmap_id":28574}
{ "id" : 3, "name" : "Alexander", "age":22, "bitmap_id":8573}
```

### 2. Create table:

```
CREATE TABLE demo.routine_test18 (
 id INT NOT NULL COMMENT "id",
 name VARCHAR(30) NOT NULL COMMENT "name",
 age INT COMMENT "age",
 bitmap_id INT COMMENT "test",
 device_id BITMAP BITMAP_UNION COMMENT "test column"
)
AGGREGATE KEY (`id`,`name`,`age`,`bitmap_id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1;
```

### 3. Load command:

```
CREATE ROUTINE LOAD demo.kafka_job18 ON routine_test18
 COLUMNS(id, name, age, bitmap_id, device_id=to_bitmap(bitmap_id))
 PROPERTIES
 (
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad18",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

### 4. Load result:

```
mysql> select id, BITMAP_UNION_COUNT(pv) over(order by id) uv from(
-> select id, BITMAP_UNION(device_id) as pv
-> from routine_test18
-> group by id
->) final;
+-----+-----+
| id | uv |
+-----+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 3 |
+-----+-----+
3 rows in set (0.00 sec)
```

## Loading HLL Data Type

### 1. Loading sample data:

```
2022-05-05,10001,Test01,Beijing,windows
2022-05-05,10002,Test01,Beijing,linux
```

```

2022-05-05,10003,Test01,Beijing,macos
2022-05-05,10004,Test01,Hebei,windows
2022-05-06,10001,Test01,Shanghai,windows
2022-05-06,10002,Test01,Shanghai,linux
2022-05-06,10003,Test01,Jiangsu,macos
2022-05-06,10004,Test01,Shaanxi,windows

```

## 2. Create table:

```

create table demo.routine_test19 (
 dt DATE,
 id INT,
 name VARCHAR(10),
 province VARCHAR(10),
 os VARCHAR(10),
 pv hll hll_union
)
Aggregate KEY (dt,id,name,province,os)
distributed by hash(id) buckets 10;

```

## 3. Load command:

```

CREATE ROUTINE LOAD demo.kafka_job19 ON routine_test19
 COLUMNS TERMINATED BY ",",
 COLUMNS(dt, id, name, province, os, pv=hll_hash(id))
FROM KAFKA
(
 "kafka_broker_list" = "10.16.10.6:9092",
 "kafka_topic" = "routineLoad19",
 "property.kafka_default_offsets" = "OFFSET_BEGINNING"
);

```

## 4. Load result:

```

mysql> select * from routine_test19;
+-----+-----+-----+-----+-----+-----+
| dt | id | name | province | os | pv |
+-----+-----+-----+-----+-----+-----+
| 2022-05-05 | 10001 | Test01 | Beijing | windows | NULL |
| 2022-05-06 | 10001 | Test01 | Shanghai | windows | NULL |
| 2022-05-05 | 10002 | Test01 | Beijing | linux | NULL |
| 2022-05-06 | 10002 | Test01 | Shanghai | linux | NULL |
| 2022-05-05 | 10004 | Test01 | Hebei | windows | NULL |
| 2022-05-06 | 10004 | Test01 | Shaanxi | windows | NULL |
| 2022-05-05 | 10003 | Test01 | Beijing | macos | NULL |
| 2022-05-06 | 10003 | Test01 | Jiangsu | macos | NULL |
+-----+-----+-----+-----+-----+-----+
8 rows in set (0.01 sec)

mysql> SELECT HLL_UNION_AGG(pv) FROM routine_test19;
+-----+
| hll_union_agg(pv) |
+-----+
| 4 |
+-----+
1 row in set (0.01 sec)

```

## Kafka Security Authentication

### Loading Kafka Data with SSL Authentication

Example load command:

```
CREATE ROUTINE LOAD demo.kafka_job20 ON routine_test20
 PROPERTIES
 (
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "192.168.100.129:9092",
 "kafka_topic" = "routineLoad21",
 "property.security.protocol" = "ssl",
 "property.ssl.ca.location" = "FILE:ca.pem",
 "property.ssl.certificate.location" = "FILE:client.pem",
 "property.ssl.key.location" = "FILE:client.key",
 "property.ssl.key.password" = "ssl_passwd"
);
```

Parameter descriptions:

Parameter	Description
property.security.protocol	The security protocol used, in this example it is SSL
property.ssl.ca.location	The location of the CA (Certificate Authority) certificate
property.ssl.certificate.location	The location of the Client's public key (required if client authentication is enabled on the Kafka server)
property.ssl.key.location	The location of the Client's private key (required if client authentication is enabled on the Kafka server)
property.ssl.key.password	The password for the Client's private key (required if client authentication is enabled on the Kafka server)

### Loading Kafka Data with Kerberos Authentication

Example load command:

```
CREATE ROUTINE LOAD demo.kafka_job21 ON routine_test21
 PROPERTIES
 (
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "192.168.100.129:9092",
 "kafka_topic" = "routineLoad21",
 "property.security.protocol" = "SASL_PLAINTEXT",
 "property.sasl.kerberos.service.name" = "kafka",
 "property.sasl.kerberos.keytab"="/opt/third/kafka/kerberos/kafka_client.keytab",
 "property.sasl.kerberos.principal" = "clients/stream.dt.local@EXAMPLE.COM"
);
```

Parameter descriptions:

Parameter	Description
property.security.protocol	The security protocol used, in this example it is SASL_PLAINTEXT
property.sasl.kerberos.service.name	Specifies the broker service name, default is Kafka
property.sasl.kerberos.keytab	The location of the keytab file
property.sasl.kerberos.principal	Specifies the Kerberos principal

## Loading Kafka Cluster with PLAIN Authentication

### 1. Example load command:

```
CREATE ROUTINE LOAD demo.kafka_job22 ON routine_test22
 PROPERTIES
 (
 "format" = "json"
)
FROM KAFKA
(
 "kafka_broker_list" = "192.168.100.129:9092",
 "kafka_topic" = "routineLoad22",
 "property.security.protocol"="SASL_PLAINTEXT",
 "property.sasl.mechanism"="PLAIN",
 "property.sasl.username"="admin",
 "property.sasl.password"="admin"
);
```

Parameter descriptions:

Parameter	Description
property.security.protocol	The security protocol used, in this example it is SASL_PLAINTEXT
property.sasl.mechanism	Specifies the SASL authentication mechanism as PLAIN
property.sasl.username	The username for SASL
property.sasl.password	The password for SASL

## Single-task Loading to Multiple Tables

Create a Kafka routine dynamic table load task named “test1” for the “example\_db”. Specify the column delimiter, group.id, and client.id. Automatically consume all partitions and start subscribing from the available data position (OFFSET\_BEGINNING).

Assuming we need to load data from Kafka into tables “tbl1” and “tbl2” in the “example\_db”, we create a Routine Load task named “test1”. This task will load data from Kafka’s topic my\_topic into both “tbl1” and “tbl2” simultaneously. This way, we can load data from Kafka into two tables using a single routine load task.

```
CREATE ROUTINE LOAD example_db.test1
FROM KAFKA
(
 "kafka_broker_list" = "broker1:9092,broker2:9092,broker3:9092",
 "kafka_topic" = "my_topic",
```

```
"property.kafka_default_offsets" = "OFFSET_BEGINNING"
);
```

Currently, only extracting the table name from the Value field of Kafka is supported. The format should be as follows, using JSON as an example: `table_name|{"col1": "val1", "col2": "val2"}`, where `tbl_name` is the table name and `|` is used as the separator between the table name and the table data. The same format applies to CSV data, such as `table_name|val1,val2,val3`. Note that the `table_name` here must be consistent with the table name in Doris, otherwise the load will fail. Note that dynamic tables do not support the `column_mapping` configuration described later.

## Strict Mode Load

Create a Kafka routine load task named “test1” for the “example\_db” and “example\_tbl”. The load task is set to strict mode.

```
CREATE ROUTINE LOAD example_db.test1 ON example_tbl
COLUMNS(k1, k2, k3, v1, v2, v3 = k1 * 100),
PRECEDING FILTER k1 = 1,
WHERE k1 < 100 and k2 like "%doris%"
PROPERTIES
(
 "strict_mode" = "true"
)
FROM KAFKA
(
 "kafka_broker_list" = "broker1:9092,broker2:9092,broker3:9092",
 "kafka_topic" = "my_topic"
);
```

## Connect to the SASL Kafka service

Here we take accessing the StreamNative message service as an example:

```
CREATE ROUTINE LOAD example_db.test1 ON example_tbl
COLUMNS(user_id, name, age)
FROM KAFKA (
 "kafka_broker_list" = "pc-xxxx.aws-mec1-test-xwivq.aws.snio.cloud:9093",
 "kafka_topic" = "my_topic",
 "property.security.protocol" = "SASL_SSL",
 "property.sasl.mechanism" = "PLAIN",
 "property.sasl.username" = "user",
 "property.sasl.password" = "token:eyJhbGxxxx",
 "property.group.id" = "my_group_id_1",
 "property.client.id" = "my_client_id_1",
 "property.enable.ssl.certificate.validation" = "false"
);
```

Note that if the trusted CA certificate path is not configured on the BE side, you need to set `"property.enable.ssl.certificate.validation" = "false"` to not verify whether the server certificate is credible.

Otherwise, you need to configure the trusted CA certificate path: `"property.ssl.ca.location" = "/path/to/ca-cert.pem"`.

## More Details

Refer to the SQL manual on [Routine Load](#). You can also enter `HELP ROUTINE LOAD` in the client command line for more help.

# Insert Into Select

---

The INSERT INTO statement supports importing the results of a Doris query into another table. INSERT INTO is a synchronous import method, where the import result is returned after the import is executed. Whether the import is successful can be determined based on the returned result. INSERT INTO ensures the atomicity of the import task, meaning that either all the data is imported successfully or none of it is imported.

## Applicable scenarios

2. If a user wants to perform ETL on existing data in a Doris table and then import it into a new Doris table, the INSERT INTO SELECT syntax is applicable.
3. In conjunction with the Multi-Catalog external table mechanism, tables from MySQL or Hive systems can be mapped via Multi-Catalog. Then, data from external tables can be imported into Doris tables using the INSERT INTO SELECT syntax.
4. Utilizing the Table Value Functions (TVFs), users can directly query data stored in object storage or files on HDFS as tables, with automatic column type inference. Then, data from external tables can be imported into Doris tables using the INSERT INTO SELECT syntax.

## Implementation

When using INSERT INTO, the import job needs to be initiated and submitted to the FE node using the MySQL protocol. The FE generates an execution plan, which includes query-related operators, with the last operator being the OlapTableSink. The OlapTableSink operator is responsible for writing the query result to the target table. The execution plan is then sent to the BE nodes for execution. Doris designates one BE node as the Coordinator, which receives and distributes the data to other BE nodes.

## Get started

An INSERT INTO job is submitted and transmitted using the MySQL protocol. The following example demonstrates submitting an import job using INSERT INTO through the MySQL command-line interface.

Detailed syntax can be found in the INSERT INTO documentation.

## Preparation

INSERT INTO requires INSERT permissions on the target table. You can grant permissions to user accounts using the GRANT command.

## Create an INSERT INTO job

1. Create a source table

```
CREATE TABLE testdb.test_table(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User name",
 age INT COMMENT "User age"
```

```
)
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

2. Import data into the source table using any load method. (Here we use `INSERT INTO VALUES` for example).

```
INSERT INTO testdb.test_table (user_id, name, age)
VALUES (1, "Emily", 25),
 (2, "Benjamin", 35),
 (3, "Olivia", 28),
 (4, "Alexander", 60),
 (5, "Ava", 17);
```

- Building upon the above operations, create a new table as the target table (with the same schema as the source table).

```
CREATE TABLE testdb.test_table2 LIKE testdb.test_table;
```

4. Ingest data into the new table using `INSERT INTO SELECT`.

```
INSERT INTO testdb.test_table2
SELECT * FROM testdb.test_table WHERE age < 30;
Query OK, 3 rows affected (0.544 sec)
{'label': 'label_9c2bae970023407d_b2c5b78b368e78a7', 'status': 'VISIBLE', 'txnId': '9084'}
```

5. View imported data.

```
MySQL> SELECT * FROM testdb.test_table2 ORDER BY age;
```

user_id	name	age
5	Ava	17
1	Emily	25
3	Olivia	28

3 rows in set (0.02 sec)

6. You can use JOB make the INSERT operation execute asynchronously.

7. Sources can be [tvf](#) or tables in a [catalog](#).

**View INSERT INTO jobs**

You can use the `SHOW LOAD` command to view the completed `INSERT INTO` tasks.

```
MySQL> SHOW LOAD FROM testdb;
```

JobId	Label	State	Progress	Type	EtlInfo
TaskInfo			ErrorMsg	CreateTime	

EtlStartTime	EtlFinishTime	LoadStartTime	LoadFinishTime	URL	JobDetails
TransactionId	ErrorTablets	User	Comment		
376416	label_3e52da787aab4222_9126d2fce8f6d1e5	FINISHED	Unknown id: 376416	INSERT	NULL
cluster:N/A; timeout(s):26200; max_filter_ratio:0.0; priority:NORMAL					
2024-02-27 01:22:17	2024-02-27 01:22:17	2024-02-27 01:22:17	2024-02-27 01:22:18		2024-02-27 01:22:17
{"Unfinished backends":{},"ScannedRows":0,"TaskNumber":0,"LoadBytes":0,"All backends":{},"FileName":0,"FileSize":0}					
9081	{}	root			
376664	label_9c2bae970023407d_b2c5b78b368e78a7	FINISHED	Unknown id: 376664	INSERT	NULL
cluster:N/A; timeout(s):26200; max_filter_ratio:0.0; priority:NORMAL					
2024-02-27 01:39:37	2024-02-27 01:39:37	2024-02-27 01:39:37	2024-02-27 01:39:38		2024-02-27 01:39:37
{"Unfinished backends":{},"ScannedRows":0,"TaskNumber":0,"LoadBytes":0,"All backends":{},"FileName":0,"FileSize":0}					
9084	{}	root			

## Cancel INSERT INTO jobs

You can cancel the currently executing INSERT INTO job via Ctrl-C.

# Manual

## Syntax

The syntax of INSERT INTO is as follows:

- ## 1. INSERT INTO SELECT

INSERT INTO SELECT is used to write the query results to the target table.

```
INSERT INTO target_table SELECT ... FROM source_table;
```

The SELECT statement above is similar to a regular SELECT query, allowing operations such as WHERE and JOIN.

## Parameter configuration

## FE Config

Name	Default Value	Description
insert_load_default_timeout_second	14400s (4 hours)	Timeout for import tasks, in seconds. If the import task does not complete within this timeout period, it will be canceled by the system and marked as CANCELLED.

### Session Variable

Name	Default Value	Description
insert_timeout	14400s (4 hours)	Timeout for INSERT INTO as an SQL statement, in seconds.
enable_insert_strict	true	If this is set to true, INSERT INTO will fail when the task involves invalid data. If set to false, INSERT INTO will ignore invalid rows, and the import will be considered successful as long as at least one row is imported successfully. Until version 2.1.4, INSERT INTO cannot control the error rate, so this parameter is used to either strictly check data quality or completely ignore invalid data. Common reasons for data invalidity include: source data column length exceeding destination column length, column type mismatch, partition mismatch, and column order mismatch.
insert_max_filter_ratio	1.0	Since version 2.1.5. Only effective when enable_insert_strict is false. Used to control the error tolerance when using INSERT INTO FROM S3/HDFS/LOCAL(). The default value is 1.0, which means all errors are tolerated. It can be a decimal between 0 and 1. It means that when the number of error rows exceeds this ratio, the INSERT task will fail.

## Return values

INSERT INTO an SQL statement, and it returns different results based on different query outcomes:

### Empty result set

If the query result set of the SELECT statement in INSERT INTO is empty, the returned value will be as follows:

```
mysql> INSERT INTO tbl1 SELECT * FROM empty_tbl;
Query OK, 0 rows affected (0.02 sec)
```

Query OK indicates successful execution. 0 rows affected means no data was imported.

### Non-empty result set and successful INSERT

```
mysql> INSERT INTO tbl1 SELECT * FROM tbl2;
Query OK, 4 rows affected (0.38 sec)
{'label': 'INSERT_8510c568-9eda-4173-9e36-6adc7d35291c', 'status': 'visible', 'txnId': '4005'}

mysql> INSERT INTO tbl1 WITH LABEL my_label1 SELECT * FROM tbl2;
Query OK, 4 rows affected (0.38 sec)
{'label': 'my_label1', 'status': 'visible', 'txnId': '4005'}

mysql> INSERT INTO tbl1 SELECT * FROM tbl2;
Query OK, 2 rows affected, 2 warnings (0.31 sec)
{'label': 'INSERT_f0747f0e-7a35-46e2-affa-13a235f4020d', 'status': 'visible', 'txnId': '4005'}
```

```
mysql> INSERT INTO tbl1 SELECT * FROM tbl2;
Query OK, 2 rows affected, 2 warnings (0.31 sec)
{'label': 'INSERT_f0747f0e-7a35-46e2-affa-13a235f4020d', 'status': 'committed', 'txnId': '4005'}
```

Query OK indicates successful execution. 4 rows affected indicates that a total of 4 rows of data have been imported. 2 warnings indicates the number of rows that were filtered out.

Additionally, a JSON string is returned:

```
{'label': 'my_label1', 'status': 'visible', 'txnId': '4005'}
{'label': 'INSERT_f0747f0e-7a35-46e2-affa-13a235f4020d', 'status': 'committed', 'txnId': '4005'}
{'label': 'my_label1', 'status': 'visible', 'txnId': '4005', 'err': 'some other error'}
```

Parameter description:

Parameter	Description
TxnId	ID of the import transaction
Label	Label of the import job: can be specified using "INSERT INTO tbl WITH LABEL label..."
Status	Visibility of the imported data: If it is visible, it will be displayed as "visible." If not, it will be displayed as "committed." In the "committed" state, the import is completed, but the data may be delayed in becoming visible. There is no need to retry in this case. visible: The import is successful and the data is visible. committed: The import is completed, but the data may be delayed in becoming visible. There is no need to retry in this case. Label Already Exists: The specified label already exists and needs to be changed to a different one. Fail: The import fails.
Err	Error message

You can use the [SHOW LOAD](#) statement to view the filtered rows.

```
SHOW LOAD WHERE label="xxx";
```

The result of this statement will include a URL that can be used to query the error data. For more details, refer to the "View error rows" section below.

The invisible state of data is temporary, and the data will eventually become visible.

You can check the visibility status of a batch of data using the [SHOW TRANSACTION](#) statement.

```
SHOW TRANSACTION WHERE id=4005;
```

If the TransactionStatus column in the result is visible, it indicates that the data is visible.

```
{'label': 'my_label1', 'status': 'visible', 'txnId': '4005'}
{'label': 'INSERT_f0747f0e-7a35-46e2-affa-13a235f4020d', 'status': 'committed', 'txnId': '4005'}
{'label': 'my_label1', 'status': 'visible', 'txnId': '4005', 'err': 'some other error'}
```

## Non-empty result set but failed INSERT

Failed execution means that no data was successfully imported. An error message will be returned:

```
mysql> INSERT INTO tbl1 SELECT * FROM tbl2 WHERE k1 = "a";
ERROR 1064 (HY000): all partitions have no load data. url: http://10.74.167.16:8042/api/_load_error_log?
file=_shard_2/error_logininsert_stmt_ba8bb9e158e4879-ae8de8507c0bf8a2_ba8bb9e158e4879-ae8de8507c0bf8a2
```

ERROR 1064 (HY000): all partitions have no load data indicates the root cause for the failure. The URL provided in the error message can be used to locate the error data. For more details, refer to the “View error rows” section below.

## Best practice

### Data size

INSERT INTO imposes no limitations on data volume and can support large-scale data imports. However, if you are importing a large amount of data, it is recommended to adjust the system's INSERT INTO timeout settings to ensure that `import timeout >= data volume / estimated import speed`.

1. FE configuration parameter `insert_load_default_timeout_second`
2. Environment parameter `insert_timeout`

### View error rows

When the INSERT INTO result includes a URL field, you can use the following command to view the error rows:

```
SHOW LOAD WARNINGS ON "url";
```

Example:

```
SHOW LOAD WARNINGS ON "http://ip:port/api/_load_error_log?
file=_shard_13/error_logininsert_stmt_d2cac0a0a16d482d-9041c949a4b71605_d2cac0a0a16d482d_9041c949a4b71605";
```

Common reasons for errors include: source data column length exceeding destination column length, column type mismatch, partition mismatch, and column order mismatch.

You can control whether INSERT INTO ignores error rows by configuring the environment variable `enable_insert_strict`.

## Ingest external data via Multi-Catalog

Doris supports the creation of external tables. Once created, data from external tables can be imported into Doris internal tables using `INSERT INTO SELECT`, or queried directly using `SELECT` statements.

With its Multi-Catalog feature, Doris supports connections to various mainstream data lakes and databases including Apache Hive, Apache Iceberg, Apache Hudi, Apache Paimon (Incubating), Elasticsearch, MySQL, Oracle, and SQL Server.

For more information on Multi-Catalog, please refer to [Lakehouse overview](#).

The followings illustrate importing data from a Hive external table into a Doris internal table.

## Create Hive Catalog

```
CREATE CATALOG hive PROPERTIES (
 'type'='hms',
 'hive.metastore.uris' = 'thrift://172.0.0.1:9083',
 'hadoop.username' = 'hive',
 'dfs.nameservices'='your-nameservice',
 'dfs.ha.namenodes.your-nameservice'='nn1,nn2',
 'dfs.namenode.rpc-address.your-nameservice.nn1'='172.21.0.2:8088',
 'dfs.namenode.rpc-address.your-nameservice.nn2'='172.21.0.3:8088',
 'dfs.client.failover.proxy.provider.your-
nameservice'='org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider'
);
```

## Ingest data

1. Create a target table for the data import in Doris.

```
CREATE TABLE `target_tbl` (
 `k1` decimal(9, 3) NOT NULL COMMENT "",
 `k2` char(10) NOT NULL COMMENT "",
 `k3` datetime NOT NULL COMMENT "",
 `k5` varchar(20) NOT NULL COMMENT "",
 `k6` double NOT NULL COMMENT ""
)
COMMENT "Doris Table"
DISTRIBUTED BY HASH(k1) BUCKETS 2
PROPERTIES (
 "replication_num" = "1"
);
```

2. For detailed instructions on creating Doris tables, please refer to [CREATE TABLE](#).
3. Importing data (from the hive.db1.source\_tbl table into the target\_tbl table).

```
INSERT INTO target_tbl SELECT k1,k2,k3 FROM hive.db1.source_tbl limit 100;
```

The INSERT command is a synchronous command. If it returns a result, that indicates successful import.

## Notes

- Ensure that the external data source and the Doris cluster can communicate, including mutual network accessibility between BE nodes and external data sources.

## Ingest data by TVF

Doris can directly query and analyze files stored in object storage or HDFS as tables through the Table Value Functions (TVFs), which supports automatic column type inference. For detailed information, please refer to the Lakehouse/TVF documentation.

## Automatic column type inference

```
DESC FUNCTION s3 (
 "URI" = "http://127.0.0.1:9312/test2/test.snappy.parquet",
 "s3.access_key"= "ak",
 "s3.secret_key" = "sk",
 "format" = "parquet",
 "use_path_style"="true"
);
```

Field	Type	Null	Key	Default	Extra
p_partkey	INT	Yes	false	NULL	NONE
p_name	TEXT	Yes	false	NULL	NONE
p_mfgr	TEXT	Yes	false	NULL	NONE
p_brand	TEXT	Yes	false	NULL	NONE
p_type	TEXT	Yes	false	NULL	NONE
p_size	INT	Yes	false	NULL	NONE
p_container	TEXT	Yes	false	NULL	NONE
p_retailprice	DECIMAL(9,0)	Yes	false	NULL	NONE
p_comment	TEXT	Yes	false	NULL	NONE

In this example of an S3 TVF, the file path, connection information, and authentication information are specified.

You can use the `DESC FUNCTION` syntax to view the schema of this file.

It can be seen that for Parquet files, Doris automatically infers column types based on the metadata within the file.

Currently, Doris supports analysis and column type inference for Parquet, ORC, CSV, and JSON formats.

It can be used in combination with the `INSERT INTO SELECT` syntax to quickly import files into Doris tables for faster analysis.

```
// 1. Create Doris internal table
CREATE TABLE IF NOT EXISTS test_table
(
 id int,
 name varchar(50),
 age int
)
DISTRIBUTED BY HASH(id) BUCKETS 4
PROPERTIES("replication_num" = "1");

// 2. Insert data by S3 Table Value Function
INSERT INTO test_table (id,name,age)
SELECT cast(id as INT) as id, name, cast (age as INT) as age
FROM s3(
 "uri" = "http://127.0.0.1:9312/test2/test.snappy.parquet",
 "s3.access_key"= "ak",
 "s3.secret_key" = "sk",
 "format" = "parquet",
 "use_path_style" = "true");
```

## Notes

- If the URI specified in the `S3 / hdfs` TVF does not match any files, or if all matched files are empty, the `S3 / hdfs` TVF will return an empty result set. In such cases, if you use `DESC FUNCTION` to view the schema of the file, you will see a dummy column `__dummy_col`, which can be ignored.
- If the format specified for the TVF is CSV and the file being read is not empty but the first line of the file is empty, an error will be prompted: `The first line is empty, can not parse column numbers.` This is because the schema cannot be parsed from the first line of the file.

## More help

For more detailed syntax on `INSERT INTO`, refer to the [INSERT INTO](#) command manual. You can also type `HELP INSERT` at the MySQL client command line for further information.

# Insert Into Values

---

The INSERT INTO VALUES statement supports importing values from SQL into a Doris table. INSERT INTO VALUES is a synchronous import method, where the import result is returned after the import is executed. Whether the import is successful can be determined based on the returned result. INSERT INTO VALUES ensures the atomicity of the import task, meaning that either all the data is imported successfully or none of it is imported.

## Applicable scenarios

1. If a user wants to import only a few test data records to verify the functionality of the Doris system, the INSERT INTO VALUES syntax is applicable. It is similar to the MySQL syntax. However, it is not recommended to use INSERT INTO VALUES in a production environment.
2. The performance of concurrent INSERT INTO VALUES jobs will be bottlenecked by commit stage. When loading large quantity of data, you can enable [group commit](#) to achieve high performance.

## Implementation

When using INSERT INTO VALUES, the import job needs to be initiated and submitted to the FE node using the MySQL protocol. The FE generates an execution plan, which includes query-related operators, with the last operator being the OlapTableSink. The OlapTableSink operator is responsible for writing the query result to the target table. The execution plan is then sent to the BE nodes for execution. Doris designates one BE node as the Coordinator, which receives and distributes the data to other BE nodes.

## Get started

An INSERT INTO VALUES job is submitted and transmitted using the MySQL protocol. The following example demonstrates submitting an import job using INSERT INTO VALUES through the MySQL command-line interface.

## Preparation

INSERT INTO VALUES requires INSERT permissions on the target table. You can grant permissions to user accounts using the GRANT command.

## Create an INSERT INTO VALUES job

### INSERT INTO VALUES

1. Create a source table

```
CREATE TABLE testdb.test_table(
 user_id BIGINT NOT NULL COMMENT "User ID",
 name VARCHAR(20) COMMENT "User name",
 age INT COMMENT "User age"
)
```

```
DUPLICATE KEY(user_id)
DISTRIBUTED BY HASH(user_id) BUCKETS 10;
```

2. Import data into the source table using `INSERT INTO VALUES` (not recommended for production environments).

```
INSERT INTO testdb.test_table (user_id, name, age)
VALUES (1, "Emily", 25),
 (2, "Benjamin", 35),
 (3, "Olivia", 28),
 (4, "Alexander", 60),
 (5, "Ava", 17);
```

`INSERT INTO VALUES` is a synchronous import method, where the import result is directly returned to the user.

```
Query OK, 5 rows affected (0.308 sec)
{'label': 'label_26eebc33411f441c_b2b286730d495e2c', 'status': 'VISIBLE', 'txnId': '61071'}
```

3. View imported data.

```
MySQL> SELECT COUNT(*) FROM testdb.test_table;
+-----+
| count(*) |
+-----+
| 5 |
+-----+
1 row in set (0.179 sec)
```

## View INSERT INTO VALUES jobs

You can use the `SHOW LOAD` command to view the completed `INSERT INTO VALUES` tasks.

```
mysql> SHOW LOAD FROM testdb\G
***** 1. row *****
 JobId: 77172
 Label: label_26eebc33411f441c_b2b286730d495e2c
 State: FINISHED
 Progress: Unknown id: 77172
 Type: INSERT
 EtlInfo: NULL
 TaskInfo: cluster:N/A; timeout(s):14400; max_filter_ratio:0.0
 ErrorMsg: NULL
 CreateTime: 2024-11-20 16:44:08
 EtlStartTime: 2024-11-20 16:44:08
 EtlFinishTime: 2024-11-20 16:44:08
 LoadStartTime: 2024-11-20 16:44:08
 LoadFinishTime: 2024-11-20 16:44:08
 URL:
 JobDetails: {"Unfinished backends": {}, "ScannedRows": 0, "TaskNumber": 0, "LoadBytes": 0, "All backends":
{},"FileName": 0, "FileSize": 0}
 TransactionId: 61071
 ErrorTablets: {}
 User: root
 Comment:
1 row in set (0.00 sec)
```

## Cancel INSERT INTO VALUES jobs

You can cancel the currently executing INSERT INTO VALUES job via Ctrl-C.

## Manual

### Syntax

INSERT INTO VALUES is typically used for testing purposes. It is not recommended for production environments.

```
INSERT INTO target_table (col1, col2, ...)
VALUES (val1, val2, ...), (val3, val4, ...), ...;
```

### Parameter configuration

#### FE Config

Name	Default Value	Description
insert_load_default_timeout_second	14400s (4 hours)	Timeout for import tasks, in seconds. If the import task does not complete within this timeout period, it will be canceled by the system and marked as CANCELLED.

#### Session Variable

Name	Default Value	Description
insert_timeout	14400s (4 hours)	Timeout for INSERT INTO as an SQL statement, in seconds.
enable_insert_strict	true	If this is set to true, INSERT INTO will fail when the task involves invalid data. If set to false, INSERT INTO will ignore invalid rows, and the import will be considered successful as long as at least one row is imported successfully. Until version 2.1.4, INSERT INTO cannot control the error rate, so this parameter is used to either strictly check data quality or completely ignore invalid data. Common reasons for data invalidity include: source data column length exceeding destination column length, column type mismatch, partition mismatch, and column order mismatch.

Name	Default Value	Description
insert_max_filter_ratio	1.0	Since version 2.1.5. Only effective when enable_insert_strict is false. Used to control the error tolerance when using INSERT INTO FROM S3/HDFS/LOCAL(). The default value is 1.0, which means all errors are tolerated. It can be a decimal between 0 and 1. It means that when the number of error rows exceeds this ratio, the INSERT task will fail.

## Return values

INSERT INTO VALUES is a SQL statement, and it returns a JSON string in its results.

Parameters in the JSON string:

Parameter	Description
Label	Label of the import job: can be specified using "INSERT INTO tbl WITH LABEL label..."
Status	Visibility of the imported data: If it is visible, it will be displayed as "visible." If not, it will be displayed as "committed." In the "committed" state, the import is completed, but the data may be delayed in becoming visible. There is no need to retry in this case. visible: The import is successful and the data is visible. committed: The import is completed, but the data may be delayed in becoming visible. There is no need to retry in this case. Label Already Exists: The specified label already exists and needs to be changed to a different one. Fail: The import fails.
Err	Error message
TxnId	ID of the import transaction

## Successful INSERT

```
mysql> INSERT INTO test_table (user_id, name, age) VALUES (1, "Emily", 25), (2, "Benjamin", 35), (3, "Olivia", 28), (NULL, "Alexander", 60), (5, "Ava", 17);
Query OK, 5 rows affected (0.05 sec)
{'label': 'label_26eebc33411f441c_b2b286730d495e2c', 'status': 'VISIBLE', 'txnId': '61071'}
```

Query OK indicates successful execution. 5 rows affected indicates that a total of 5 rows of data have been imported.

## Successful INSERT with warnings

```
mysql> INSERT INTO test_table (user_id, name, age) VALUES (1, "Emily", 25), (2, "Benjamin", 35), (3, "Olivia", 28), (NULL, "Alexander", 60), (5, "Ava", 17);
Query OK, 4 rows affected, 1 warning (0.04 sec)
{'label': 'label_a8d99ae931194d2b_93357aac59981a18', 'status': 'VISIBLE', 'txnId': '61068'}
```

Query OK indicates successful execution. 4 rows affected indicates that a total of 4 rows of data have been imported. 1 warnings indicates the number of rows that were filtered out.

You can use the [SHOW LOAD](#) statement to view the filtered rows.

The result of this statement will include a URL that can be used to query the error data. For more details, refer to the “View error rows” section below.

```
mysql> SHOW LOAD WHERE label="label_a8d99ae931194d2b_93357aac59981a18"\G
***** 1. row *****
 JobId: 77158
 Label: label_a8d99ae931194d2b_93357aac59981a18
 State: FINISHED
 Progress: Unknown id: 77158
 Type: INSERT
 EtlInfo: NULL
 TaskInfo: cluster:N/A; timeout(s):14400; max_filter_ratio:0.0
 ErrorMsg: NULL
 CreateTime: 2024-11-20 16:35:40
 EtlStartTime: 2024-11-20 16:35:40
 EtlFinishTime: 2024-11-20 16:35:40
 LoadStartTime: 2024-11-20 16:35:40
 LoadFinishTime: 2024-11-20 16:35:40
 URL: http://10.16.10.7:8743/api/_load_error_log?
file=__shard_18/error_log_insert_stmt_a8d99ae931194d2b-93357aac59981a19_a8d99ae931194d2b_93357aac59981a19
 JobDetails: {"Unfinished backends":{}, "ScannedRows":0, "TaskNumber":0, "LoadBytes":0, "All backends":
{"", "FileName":0, "FileSize":0}
 TransactionId: 61068
 ErrorTablets: {}
 User: root
 Comment:
1 row in set (0.00 sec)
```

### Successful INSERT with committed status

```
mysql> INSERT INTO test_table (user_id, name, age) VALUES (1, "Emily", 25), (2, "Benjamin", 35), (3,
"Olivia", 28), (4, "Alexander", 60), (5, "Ava", 17);
Query OK, 5 rows affected (0.04 sec)
{'label': 'label_78bf5396d9594d4d_a8d9a914af40f73d', 'status': 'COMMITTED', 'txnId': '61074'}
```

The invisible state of data is temporary, and the data will eventually become visible.

You can check the visibility status of a batch of data using the [SHOW TRANSACTION](#) statement.

If the TransactionStatus column in the result is visible, it indicates that the data is visible.

```
mysql> SHOW TRANSACTION WHERE id=61074\G
***** 1. row *****
 TransactionId: 61074
 Label: label_78bf5396d9594d4d_a8d9a914af40f73d
 Coordinator: FE: 10.16.10.7
 TransactionStatus: VISIBLE
 LoadJobSourceType: INSERT_STREAMING
 PrepareTime: 2024-11-20 16:51:54
 PreCommitTime: NULL
 CommitTime: 2024-11-20 16:51:54
 PublishTime: 2024-11-20 16:51:54
 FinishTime: 2024-11-20 16:51:54
 Reason:
 ErrorReplicasCount: 0
 ListenerId: -1
 TimeoutMs: 14400000
 ErrMsg:
1 row in set (0.00 sec)
```

## Non-empty result set but failed INSERT

Failed execution means that no data was successfully imported. An error message will be returned:

```
mysql> INSERT INTO test_table (user_id, name, age) VALUES (1, "Emily", 25), (2, "Benjamin", 35), (3, "Olivia", 28), (NULL, "Alexander", 60), (5, "Ava", 17);
ERROR 1105 (HY000): errCode = 2, detailMessage = Insert has too many filtered data 1/5
insert_max_filter_ratio is 0.100000. url: http://10.16.10.7:8747/api/_load_error_log?
file=__shard_22/error_log_insert_stmt_5fafa6663e1a45e0-a666c1722ffc8c55_5fafa6663e1a45e0_a666c1722ffc8c55
```

ERROR 1105 (HY000): errCode = 2, detailMessage = Insert has too many filtered data 1/5 insert\_max\_filter\_ratio is 0.100000. indicates the root cause for the failure. The URL provided in the error message can be used to locate the error data. For more details, refer to the “View error rows” section below.

## Best practice

### Data size

INSERT INTO VALUES is usually used for test and demo, it is not recommended to load large quantity data with INSERT INTO VALUES.

### View error rows

When the INSERT INTO result includes a URL field, you can use the following command to view the error rows:

```
SHOW LOAD WARNINGS ON "url";
```

Example:

```
mysql> SHOW LOAD WARNINGS ON "http://10.16.10.7:8743/api/_load_error_log?
file=__shard_18/error_log_insert_stmt_a8d99ae931194d2b-93357aac59981a19_a8d99ae931194d2b_93357aac59981a19"\G
***** 1. row *****
 JobId: -1
 Label: NULL
ErrorMsgDetail: Reason: column_name[user_id], null value for not null column, type=BIGINT. src line [];
1 row in set (0.00 sec)
```

Common reasons for errors include: source data column length exceeding destination column length, column type mismatch, partition mismatch, and column order mismatch.

You can control whether INSERT INTO ignores error rows by configuring the environment variable `enable_insert_strict`.

## More help

For more detailed syntax on INSERT INTO, refer to the [INSERT INTO](#) command manual. You can also type `HELP INSERT` at the MySQL client command line for further information.

# MySQL Load

---

Apache Doris is compatible with the MySQL protocol and supports the use of the standard MySQL [LOAD DATA](#) syntax to import local files. MySQL Load is a synchronous import method where the import result is returned upon completion. That means users can tell whether the import succeeds from the returned result. Generally, the MySQL Load method can be used to ingest files smaller than 10GB in size. For files larger than 10GB, it is recommended to split them into smaller ones. MySQL Load ensures the atomicity of a batch of import tasks, meaning that either all imports succeed or all imports fail.

## Applicable scenarios

### Supported format

MySQL Load is primarily designed for importing CSV files from the client's local machine or importing data from data streams through programs.

### Restrictions

When importing CSV files, it is important to differentiate between null values and empty strings (""):

- Null values are represented by the escape sequence `\N`. For example, in `a,\N,b`, the middle column represents a null value.
- Empty strings are represented directly as empty, such as `a, ,b`, where the middle column represents an empty string.

## Implementation

MySQL Load is similar to Stream Load in terms of functionality. They both involve importing local files into the Doris cluster. Therefore, the implementation of MySQL Load reuses the basic import capabilities of Stream Load.

The main processes of MySQL Load include:

1. The user submits a `LOAD DATA` request to the frontend (FE), which performs the parsing and encapsulates the request into a Stream Load task.
2. The FE selects a backend (BE) node and sends the Stream Load request to it.
3. Meanwhile, the FE reads the local file data from the MySQL client in an asynchronous and streaming manner and sends it in real time to the HTTP request of the Stream Load.
4. Once the data transfer from the MySQL client is complete, the FE waits for the Stream Load to finish and displays the import result (success or failure) to the client.

## Get started

### Preparations

MySQL Load requires `INSERT` permission on the target table. You can grant permissions to user account using the `GRANT` command.

## Create a MySQL Load job

### 1. Prepare the test data

Create a data file `client_local.csv` containing the following sample data:

```
1,10
2,20
3,30
4,40
5,50
6,60
```

### 2. Connect to MySQL client

Connect to the MySQL client before executing the LOAD DATA command:

```
mysql --local-infile -h <fe_ip> -P <fe_query_port> -u root -D testdb
```

#### Specific parameter options need to be used during the connection:

1. When connecting to the MySQL client, `--local-infile` must be included, otherwise an error might be thrown.
2. When connecting via JDBC, `allowLoadLocalInfile=true` must be specified in the URL.

### 3. Create the test table

Create a table as follows in Doris:

```
CREATE TABLE testdb.t1 (
 pk INT,
 v1 INT SUM
) AGGREGATE KEY (pk)
DISTRIBUTED BY hash (pk);
```

### 4. Run the LOAD DATA command

After connecting to the MySQL client, create a Load job. The command is as follows:

```
LOAD DATA LOCAL
INFILE 'client_local.csv'
INTO TABLE testdb.t1
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n';
```

## View results

MySQL Load is a synchronous import method, and the results of the import are returned to the user in the command-line interface. If the import execution fails, it will display specific error messages.

Below is an example of a successful import result, which returns the number of imported rows:

```
Query OK, 6 rows affected (0.17 sec)
Records: 6 Deleted: 0 Skipped: 0 Warnings: 0
```

When there are exceptions during the import, the corresponding error will be displayed on the client:

```
ERROR 1105 (HY000): errCode = 2, detailMessage = [DATA_QUALITY_ERROR]too many filtered rows with load id
b612907c-ccf4-4ac2-82fe-107ece655f0f
```

The loadId is included in the error message, based on which you can view the detailed information via the `show load warnings` command:

```
show load warnings where label='b612907c-ccf4-4ac2-82fe-107ece655f0f';
```

## Cancel a MySQL Load job

Doris does not allow manual cancellation of MySQL Load jobs. In the event of a timeout or import error, the corresponding MySQL Load job will be automatically cancelled by the system.

## Manual

### Syntax

The syntax for LOAD DATA is as follows:

```
LOAD DATA LOCAL
INFILE '<load_data_file>'
INTO TABLE [<db_name>.<table_name>
[PARTITION (partition_name [, partition_name] ...)]
[COLUMNS TERMINATED BY '<column_terminated_operator>']
[LINES TERMINATED BY '<line_terminated_operator>']
[IGNORE <ignore_lines> LINES]
[(col_name_or_user_var[, col_name_or_user_var] ...)]
[SET col_name={expr | DEFAULT}[, col_name={expr | DEFAULT}] ...]
[PROPERTIES (key1 = value1 [, key2=value2])]
```

Descriptions of modules in the Load job:

Module	Description
INFILE	This specifies the local file path, which can be either a relative path or an absolute path. Currently, load_data_file only supports a single file.
INTO TABLE	This specifies the database and table, and the database name can be omitted.
PARTITION	This specifies the target partition. If the user can determine the partition corresponding to the data, it is recommended to specify this. Data that does not fit into the specified partitions will be filtered out.
COLUMNS TERMINATED BY	This specifies the column delimiter.
LINE TERMINATED BY	This specifies the row delimiter.

Module	Description
IGNORE num LINES	This specifies the number of rows to skip in the CSV import, typically specified as 1 to skip the header.
col_name_or_user_var	This specifies the column mapping syntax. For more information, refer to <a href="#">Column Mapping</a> .
PROPERTIES	Parameters for the Load.

## Parameters

By the PROPERTIES (key1 = value1 [, key2=value2]) syntax, you can configure the parameters for the Load.

Parameter	Description
max_filter_ratio	The maximum filtering rate allowed. Must be between 0 and 1, inclusive. The default value is 0, indicating no tolerance for any error rows.
timeout	The import timeout, measured in seconds. The default value is 600. The range allowed is from 1s to 259200s.
strict_mode	Whether to enable strict mode for this import. Disabled by default.
timezone	The time zone for this import. The default time zone is UTC+8. This parameter will affect the results of any time zone-related functions involved in the import.
exec_mem_limit	Memory limit for the import, defaults to 2GB, measured in bytes.
trim_double_quotes	Boolean, defaults to false. If this is set to true, the outermost double quotes will be trimmed from each field in the import file.
enclose	This specifies the enclosure character. When a CSV data field contains line breaks or column delimiters, you can specify a single-byte character as the enclosure character to prevent accidental truncation. For example, if the column delimiter is ",", and the enclosure character is "'", in data"a,b,c", "b,c" will be parsed as one field.
escape	This specifies the escape character. This is used when the data contains the same character as the enclosure character, which needs to be treated as part of the field. For example, if the data is "a,b,'c'", the enclosure character is "'", and you want"b,'c" to be parsed as one field, you need to specify a single-byte escape character, such as "\"", to modify the data to"a,b,'c'".

## Example

### Specify load timeout

You can adjust the import timeout by specifying timeout in PROPERTIES. For example, set it to 100s:

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
PROPERTIES ("timeout"="100");
```

## Specify allowable error rate

You can adjust the allowable error rate by specifying `max_filter_ratio` in `PROPERTIES`. For example, set it to 20%:

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
PROPERTIES ("max_filter_ratio"="0.2");
```

## Import column mapping

The following example adjusts the order of columns in the CSV file.

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
(k2, k1, v1);
```

## Specify column and row delimiters

You can specify the column and row delimiters using the `COLUMNS TERMINATED BY` and `LINES TERMINATED BY` clauses. In the following example, `(,)` and `()` are used as the column and row delimiters, respectively.

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n';
```

## Specify target partition

You can specify the target partition for the import using the `PARTITION` clause. In the following example, data will be loaded into the specified partitions 'p1' and 'p2', and any data that does not belong to these two partitions will be filtered out:

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
PARTITION (p1, p2);
```

## Specify time zone

You can specify the timezone in `PROPERTIES`. In the following example, the timezone is set to Africa/Abidjan:

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
PROPERTIES ("timezone"="Africa/Abidjan");
```

## Specify the memory limit for the import

You can specify the memory limit for the import by the `exec_mem_limit` parameter in `PROPERTIES`. In the following example, the memory limit is set to 10G:

```
LOAD DATA LOCAL
INFILE 'testData'
INTO TABLE testDb.testTbl
PROPERTIES ("exec_mem_limit"="10737418240");
```

## More help

For more detailed syntax and best practices related to MySQL Load, refer to the [MySQL Load](#) command manual.

# Log Storage and Analysis | Doris Docs

---

Logs record key events in the system and contain crucial information such as the events' subject, time, location, and content. To meet the diverse needs of observability in operations, network security monitoring, and business analysis, enterprises might need to collect scattered logs for centralized storage, querying, and analysis to extract valuable content from the log data further.

In this scenario, Apache Doris provides a corresponding solution. With the characteristics of log scenarios in mind, Apache Doris added inverted-index and ultra-fast full-text search capabilities, optimizing write performance and storage space to the extreme. This allows users to build an open, high-performance, cost-effective, and unified log storage and analysis platform based on Apache Doris.

Focused on this solution, this chapter contains the following 3 sections:

- **Overall architecture:** This section explains the core components and architecture of the log storage and analysis platform built on Apache Doris.
- **Features and advantages:** This section explains the features and advantages of the log storage and analysis platform built on Apache Doris.
- **Operational guide:** This section explains how to build a log storage and analysis platform based on Apache Doris.

## Overall architecture

The following figure illustrates the architecture of the log storage and analysis platform built on Apache Doris:

Overall architecture

The architecture contains the following 3 parts:

- **Log collection and preprocessing:** Various log collection tools can write log data into Apache Doris through HTTP APIs.
- **Log storage and analysis engine:** Apache Doris provides high-performance, low-cost unified log storage, offering rich retrieval and analysis capabilities through SQL interfaces.

- **Log analysis and alert interface:** Various log retrieval and analysis tools can query Apache Doris through standard SQL interfaces, providing users with a simple and user-friendly interface.

## Features and advantages

The following figure illustrates the architecture of the log storage and analysis platform built on Apache Doris::

- **High throughput, low latency log writing:** Supports stable writing of log data at the level of hundreds of TBs and GB/s per day, while maintaining latency within 1 second.
- **Cost-effective storage of massive log data:** Supports petabyte-scale storage, saving 60% to 80% in storage costs compared to Elasticsearch, and further reducing storage costs by 50% by storing cold data in S3/HDFS.
- **High-performance log full-text search and analysis:** Supports inverted indexes and full-text search, providing second-level response times for common log queries (keyword searches, trend analysis, etc.).
- **Open and user-friendly upstream and downstream ecosystem:** Upstream integration with common log collection systems and data sources such as Logstash, Filebeat, Fluentbit, and Kafka through Stream Load's universal HTTP APIs, and downstream integration with various visual analytics UIs using standard MySQL protocol and syntax, such as observability platform Grafana, BI analytics Superset, and log retrieval Doris WebUI similar to Kibana.

## Cost-effective performance

After Benchmark testing and production validation, the log storage and analysis platform built on Apache Doris has a 5 to 10 times cost-performance advantage over Elasticsearch. Apache Doris's performance benefits are mainly due to its globally leading high-performance storage and query engine, as well as specialized optimizations for log scenarios:

- **Improved write throughput:** Elasticsearch's write performance bottleneck lies in CPU consumption for parsing data and building inverted indexes. In comparison, Apache Doris has optimized writes in two aspects: using SIMD and other CPU vector instructions to improve JSON data parsing speed and index-building performance and simplifying the inverted index structure for log scenarios by removing unnecessary data structures like forward indexes, effectively reducing index build complexity. With the same resources, Apache Doris's write performance is 3 to 5 times higher than Elasticsearch.
- **Reduced Storage Costs:** The storage bottleneck in Elasticsearch lies in the multiple storage formats for forward indexes, inverted indexes, and Docvalue columns, as well as the relatively low compression ratio of its general compression algorithms. In contrast, Apache Doris has made the following optimizations in storage: it removes the forward index, reducing the index data size by 30%; it uses columnar storage and the Zstandard compression algorithm, achieving a compression ratio of 5 to 10 times, which is significantly higher than Elasticsearch's 1.5 times; in log data, cold data is accessed very infrequently, and Apache Doris's hot and cold data tiering feature can automatically store logs that exceed a defined time period into lower-cost object storage, reducing the storage cost of cold data by more than 70%. For the same raw data, Doris's storage costs are only about 20% of those of Elasticsearch.

## Strong analytical capabilities

Apache Doris supports standard SQL and is compatible with MySQL protocol and syntax. Therefore, log systems built on Apache Doris can use SQL for log analysis, giving the following advantages to log systems:

- **Easy to use:** Engineers and data analysts are very familiar with SQL, their expertise can be reused, no need to learn new technology stacks to quickly get started.
- **Rich ecosystem:** The MySQL ecosystem is the most widely used language in the database field, seamlessly integrating with and applying to the MySQL ecosystem. Doris can leverage MySQL command line and various GUI tools, BI tools, and other big data ecosystem tools for more complex and diverse data processing and analysis needs.
- **Strong analytical capabilities:** SQL has become the de facto standard for database and big data analysis, with powerful expressive capabilities and functions supporting retrieval, aggregation, multi-table JOIN, subqueries, UDFs, logical views, materialized views, and various data analysis capabilities.

## Flexible Schema

Here is a typical example of a semi-structured log in JSON format. The top-level fields are some fixed fields, such as timestamp, source, node, component, level, clientRequestId, message, and properties, which are present in every log entry. The nested fields of the properties, such as properties.size and properties.format are more dynamic, and the fields of each log may vary.

```
{
 "timestamp": "2014-03-08T00:50:03.8432810Z",
 "source": "ADOPTIONCUSTOMERS81",
 "node": "Engine000000000405",
 "level": "Information",
 "component": "DOWNLOADER",
 "clientRequestId": "671db15d-abad-94f6-dd93-b3a2e6000672",
 "message": "Downloading file path: benchmark/2014/ADOPTIONCUSTOMERS81_94_0.parquet.gz",
 "properties": {
 "size": 1495636750,
 "format": "parquet",
 "rowCount": 855138,
 "downloadDuration": "00:01:58.3520561"
 }
}
```

Apache Doris provides several aspects of support for Flexible Schema log data:

- For changes to top-level fields, Light Schema Change can be used to add or remove columns and to add or remove indexes, enabling schema changes to be completed in seconds. When planning a log platform, users only need to consider which fields need to be indexed.
- For extension fields similar to properties, the native semi-structured data type VARIANT is provided, which can write any JSON data, automatically recognize field names and types in JSON, and automatically split frequently occurring fields for columnar storage for subsequent analysis. Additionally, VARIANT can create inverted indexes to accelerate internal field queries and retrievals.

Compared to Elasticsearch's Dynamic Mapping, Apache Doris's Flexible Schema has the following advantages:

- Allows a field to have multiple types, VARIANT automatically handles conflicts and type promotion for fields, better adapting to iterative changes in log data.
- VARIANT automatically merges infrequently occurring fields into a column store to avoid performance issues caused by excessive fields, metadata, or columns.
- Not only can columns be dynamically added, but they can also be dynamically deleted, and indexes can be dynamically added or removed, eliminating the need to index all fields at the beginning like Elasticsearch, reducing unnecessary costs.

## Operational guide

### Step 1: Estimate resources

Before deploying the cluster, you need to estimate the hardware resources required for the servers. Follow the steps below:

1. Estimate the resources for data writing by the following calculation formulas:
  - Average write throughput = Daily data increment / 86400 s
  - Peak write throughput = Average write throughput \\* Ratio of the peak write throughput to the average write throughput
  - Number of CPU cores for the peak write throughput = Peak write throughput / Write throughput of a single-core CPU
1. Estimate the resources for data storage by the calculation formula: Storage space = Daily data increment / Data compression ratio \* Number of data copies \* Data storage duration.
2. Estimate the resources for data querying. The resources for data querying depend on the query volume and complexity. It is recommended to reserve 50% of CPU resources for data query initially and then adjust according to the actual test results.
3. Integrate the calculation results as follows:
  1. Divide the number of CPU cores calculated in Step 1 and Step 3 by the number of CPU cores of a BE server, and you can get the number of BE servers.
  2. Based on the number of BE servers and the calculation result of Step 2, estimate the storage space required for each BE server.
  3. Allocate the storage space required for each BE server to 4 to 12 data disks, and you can get the storage capacity required for a single data disk.

For example, suppose that the daily data increment is 100 TB, the data compression ratio is 5, the number of data copies is 1, the storage duration of hot data is 3 days, the storage duration of cold data is 30 days, the ratio of the peak write throughput to the average write throughput is 200%, the write throughput of a single-core CUP is 10 MB/s, and 50% of CPU resources are reserved for data querying, one can estimate that:

- 3 FE servers are required, each configured with a 16-core CPU, 64 GB memory, and an 1 100 GB SSD disk.

- 15 BE servers are required, each configured with a 32-core CPU, 256 GB memory, and 10 600 GB SSD disks.
- S3 object storage space 600 TB

Refer to the following table to learn about the values of indicators in the example above and how they are calculated.

Indicator (Unit)	Value	Description
Daily data increment (TB)	100	Specify the value according to your actual needs.
Data compression ratio	5	Specify the value according to your actual needs, which is often between 3 to 10. Note that the data contains index data.
Number of data copies	1	Specify the value according to your actual needs, which can be 1, 2, or 3. The default value is 1.
Storage duration of hot data (day)	3	Specify the value according to your actual needs.
Storage duration of cold data (day)	30	Specify the value according to your actual needs.
Data storage duration	33	Calculation formula: Storage duration of hot data + Storage duration of cold data
Estimated storage space for hot data (TB)	60	Calculation formula: Daily data increment / Data compression ratios * Number of data copies * Storage duration of hot data
Estimated storage space for cold data (TB)	600	Calculation formula: Daily data increment / Data compression ratios * Number of data copies * Storage duration of cold data
Ratio of the peak write throughput to the average write throughput	200%	Specify the value according to your actual needs. The default value is 200%.
Number of CPU cores of a BE server	32	Specify the value according to your actual needs. The default value is 32.
Average write throughput (MB/s)	1214	Calculation formula: Daily data increment / 86400 s
Peak write throughput (MB/s)	2427	Calculation formula: Average write throughput * Ratio of the peak write throughput to the average write throughput
Number of CPU cores for the peak write throughput	242.7	Calculation formula: Peak write throughput / Write throughput of a single-core CPU
Percent of CPU resources reserved for data querying	50%	Specify the value according to your actual needs. The default value is 50%.

Indicator (Unit)	Value	Description
Estimated number of BE servers	15.2	Calculation formula: Number of CPU cores for the peak write throughput / Number of CPU cores of a BE server / (1 - Percent of CPU resources reserved for data querying)
Rounded number of BE servers	15	Calculation formula: MAX (Number of data copies, Estimated number of BE servers)
Estimated data storage space for each BE server (TB)	5.7	Calculation formula: Estimated storage space for hot data / Estimated number of BE servers / (1 - 30%), where 30% represents the percent of reserved storage space.  It is recommended to mount 4 to 12 data disks on each BE server to enhance I/O capabilities.

## Step 2: Deploy the cluster

After estimating the resources, you need to deploy the cluster. It is recommended to deploy in both physical and virtual environments manually. For manual deployment, refer to [Manual Deployment](#).

## Step 3: Optimize FE and BE configurations

After completing the cluster deployment, it is necessary to optimize the configuration parameters for both the front-end and back-end separately, so as to better suit the scenario of log storage and analysis.

### Optimize FE configurations

You can find FE configuration fields in `fe/conf/fe.conf`. Refer to the following table to optimize FE configurations.

Configuration fields to be optimized	Description
<code>max_running_txn_num_per_db = 10000</code>	Increase the parameter value to adapt to high-concurrency import transactions.
<code>streaming_label_keep_max_second = 3600</code> <code>label_keep_max_second = 7200</code>	Increase the retention time to handle high-frequency import transactions with high memory usage.
<code>enable_round_robin_create_tablet = true</code>	When creating Tablets, use a Round Robin strategy to distribute evenly.
<code>tablet_rebalancer_type = partition</code>	When balancing Tablets, use a strategy to evenly distribute within each partition.
<code>autobucket_min_buckets = 10</code>	Increase the minimum number of automatically bucketed buckets from 1 to 10 to avoid insufficient buckets when the log volume increases.

Configuration fields to be optimized	Description
max_backend_heartbeat_failure_tolerance_count = 10	In log scenarios, the BE server may experience high pressure, leading to short-term timeouts, so increase the tolerance count from 1 to 10.

For more information, refer to [FE Configuration](#).

## Optimize BE configurations

You can find BE configuration fields in `be/conf/be.conf`. Refer to the following table to optimize BE configurations.

Module	Configuration fields to be optimized	Description
Storage	storage_root_path = /path/to/dir1;/path/to/dir2;...;/path/to/dir12	Configure the storage path for hot data on disk directories.
-	enable_file_cache = true	Enable file caching.
-	file_cache_path = [{"path": "/mnt/datadisk0/file_cache", "total_size":53687091200, "query_limit": "10737418240"}], [{"path": "/mnt/datadisk1/file_cache", "total_size":53687091200, "query_limit": "10737418240"}]	Configure the cache path and related settings for cold data with the following specific configurations: path: cache path total_size: total size of the cache path in bytes, where 53687091200 bytes equals 50 GB query_limit: maximum amount of data that can be queried from the cache path in one query in bytes, where 10737418240 bytes equals 10 GB
Write	write_buffer_size = 1073741824	Increase the file size of the write buffer to reduce small files and random I/O operations, improving performance.
-	max_tablet_version_num = 20000	In coordination with the time_series compaction strategy for table creation, allow more versions to remain temporarily unmerged. No longer required after version 2.1.11, as there is a time_series_max_tablet_version_num configuration
Compaction	max_cumu_compaction_threads = 8	Set to CPU core count / 4, indicating that 1/4 of CPU resources are used for writing, 1/4 for background compaction, and 2/1 for queries and other operations.
-	inverted_index_compaction_enable = true	Enable inverted index compaction to reduce CPU consumption during compaction.
-	enable_segcompaction = false enable_ordered_data_compaction = false	Disable two compaction features that are unnecessary for log scenarios.
-	enable_compaction_priority_scheduling = false	Low-priority compaction is limited to 2 tasks on a single disk, which can affect the speed of compaction.
-	total_permits_for_compaction_score = 200000	The parameter is used to control memory, under the memory time series strategy, the parameter itself can control memory.
Cache	disable_storage_page_cache = true inverted_index_searcher_cache_limit = 30%	Due to the large volume of log data and limited caching effect, switch from data caching to index caching.
-	inverted_index_cache_stale_sweep_time_sec = 3600 index_cache_entry_stay_time_after_lookup_s = 3600	Maintain index caching in memory for up to 1 hour.

Module	Configuration fields to be optimized	Description
-	enable_inverted_index_cache_on_cooldown = true enable_write_index_searcher_cache = false	Enable automatic caching of cold data storage during index uploading.
-	tablet_schema_cache_recycle_interval = 3600 segment_cache_capacity = 20000	Reduce memory usage by other caches.
-	inverted_index_ram_dir_enable = true	Reduce the IO overhead caused by writing to index files temporarily.
Thread	pipeline_executor_size = 24 doris_scanner_thread_pool_thread_num = 48	Configure computing threads and I/O threads for a 32-core CPU in proportion to core count.
-	scan_thread_nice_value = 5	Lower the priority of query I/O threads to ensure writing performance and timeliness.
Other	string_type_length_soft_limit_bytes = 10485760	Increase the length limit of string-type data to 10 MB.
-	trash_file_expire_time_sec = 300 path_gc_check_interval_second = 900 path_scan_interval_second = 900	Accelerate the recycling of trash files.

For more information, refer to [BE Configuration](#).

## Step 4: Create tables

Due to the distinct characteristics of both writing and querying log data, it is recommended to configure tables with targeted settings to enhance performance.

### Configure data partitioning and bucketing

- For data partitioning:
  - Enable [range partitioning](#) (PARTITION BY RANGE(ts)) with [dynamic partitions](#) ("dynamic\_partition.enable" = "true") managed automatically by day.
  - Use a field in the DATETIME type as the key (DUPLICATE KEY(ts)) for accelerated retrieval of the latest N log entries.
- For data bucketing:
  - Configure the number of buckets to be roughly three times the total number of disks in the cluster, with each bucket containing approximately 5GB of data after compression.
  - Use the Random strategy (DISTRIBUTED BY RANDOM BUCKETS 60) to optimize batch writing efficiency when paired with single tablet imports.

For more information, refer to [Data Partitioning](#).

### Configure compression parameters

Use the zstd compression algorithm ("compression" = "zstd") to improve data compression efficiency.

### Configure compaction parameters

Configure compaction fields as follows:

- Use the time\_series strategy ("compaction\_policy" = "time\_series") to reduce write amplification, which is crucial for high-throughput log writes.

### Configure index parameters

Configuring index fields as follows:

- Create indexes for fields that are frequently queried (USING INVERTED).
- For fields that require full-text search, specify the parser field as unicode, which satisfies most requirements. If there is a need to support phrase queries, set the support\_phrase field to true; if not needed, set it to false to reduce storage space.

### Configure storage parameters

Configure storage policies as follows:

- For storage of hot data, if using cloud storage, configure the number of data copies as 1; if using physical disks, configure the number of data copies as at least 2 ("replication\_num" = "2").
- Configure the storage location for log\_s3 (CREATE RESOURCE "log\_s3") and set the log\_policy\_3day policy (CREATE STORAGE POLICY log\_policy\_3day), where the data is cooled and moved to the specified storage location of log\_s3 after 3 days. Refer to the code below.

```
CREATE DATABASE log_db;
USE log_db;

CREATE RESOURCE "log_s3"
PROPERTIES
(
 "type" = "s3",
 "s3.endpoint" = "your_endpoint_url",
 "s3.region" = "your_region",
 "s3.bucket" = "your_bucket",
 "s3.root.path" = "your_path",
 "s3.access_key" = "your_ak",
 "s3.secret_key" = "your_sk"
);

CREATE STORAGE POLICY log_policy_3day
PROPERTIES(
 "storage_resource" = "log_s3",
 "cooldown_ttl" = "259200"
);

CREATE TABLE log_table
(
 `ts` DATETIME,
 `host` TEXT,
 `path` TEXT,
 `message` TEXT,
 INDEX idx_host (`host`) USING INVERTED,
 INDEX idx_path (`path`) USING INVERTED,
 INDEX idx_message (`message`) USING INVERTED PROPERTIES("parser" = "unicode", "support_phrase" = "true")
)
ENGINE = OLAP
DUPLICATE KEY(`ts`)
```

```

PARTITION BY RANGE(`ts`) ()
DISTRIBUTED BY RANDOM BUCKETS 60
PROPERTIES (
 "compression" = "zstd",
 "compaction_policy" = "time_series",
 "dynamic_partition.enable" = "true",
 "dynamic_partition.create_history_partition" = "true",
 "dynamic_partition.time_unit" = "DAY",
 "dynamic_partition.start" = "-30",
 "dynamic_partition.end" = "1",
 "dynamic_partition.prefix" = "p",
 "dynamic_partition.buckets" = "60",
 "dynamic_partition.replication_num" = "2", -- unnecessary for the compute-storage coupled mode
 "replication_num" = "2", -- unnecessary for the compute-storage coupled mode
 "storage_policy" = "log_policy_3day" -- unnecessary for the compute-storage coupled mode
);

```

## Step 5: Collect logs

After completing table creation, you can proceed with log collection.

Apache Doris provides open and versatile Stream HTTP APIs, through which you can connect with popular log collectors such as Logstash, Filebeat, Kafka, and others to carry out log collection work. This section explains how to integrate these log collectors using the Stream HTTP APIs.

### Integrating Logstash

Follow these steps:

1. Download and install the Logstash Doris Output plugin. You can choose one of the following two methods:
  - [Click to download](#) and install.
  - Compile from the source code and run the following command to install:

```
./bin/logstash-plugin install logstash-output-doris-1.2.0.gem
```

2. Configure Logstash. Specify the following fields:

- `logstash.yml`: Used to configure Logstash batch processing log sizes and timings for improved data writing performance.

Plain Text `pipeline.batch.size: 1000000 pipeline.batch.delay: 10000`

- `logstash_demo.conf`: Used to configure the specific input path of the collected logs and the settings for output to Apache Doris.

```

input {
 file {
 path => "/path/to/your/log"
 }
}

output {
 doris {

```

```

http_hosts => ["<http://fehost1:http_port>", "<http://fehost2:http_port>", "<http://fehost3:http_port>"]
user => "your_username"
password => "your_password"
db => "your_db"
table => "your_table"

doris stream load http headers
headers => {
 "format" => "json"
 "read_json_by_line" => "true"
 "load_to_single_tablet" => "true"
}

field mapping: doris field name => logstash field name
%{} to get a logstash field, [] for nested field such as [host][name] for host.name
mapping => {
 "ts" => "%{@timestamp}"
 "host" => "%{[host][name]}"
 "path" => "%{[log][file][path]}"
 "message" => "%{message}"
}
log_request => true
log_speed_interval => 10
}
}
...

3. Run Logstash according to the command below, collect logs, and output to Apache Doris.

```shell
./bin/logstash -f logstash_demo.conf

```

For more information about the Logstash Doris Output plugin, see [Logstash Doris Output Plugin](#).

Integrating Filebeat

Follow these steps:

1. Obtain the Filebeat binary file that supports output to Apache Doris. You can [click to download](#) or compile it from the Apache Doris source code.
2. Configure Filebeat. Specify the filebeat_demo.yml field that is used to configure the specific input path of the collected logs and the settings for output to Apache Doris.

```

# input
filebeat.inputs:
- type: log
  enabled: true
  paths:
    - /path/to/your/log
  multiline:
    type: pattern
    pattern: '^[0-9]{4}-[0-9]{2}-[0-9]{2} [0-9]{2}:[0-9]{2}:[0-9]{2}'
    negate: true
    match: after
    skip_newline: true

processors:
- script:
    lang: javascript
    source: >

```

```

        function process(event) {
            var msg = event.Get("message");
            msg = msg.replace(/\t/g, " ");
            event.Put("message", msg);
        }
- dissect:
    # 2024-06-08 18:26:25,481 INFO (report-thread|199) [ReportHandler.cpuReport():617] begin to handle
    tokenizer: "%{day} %{time} %{log_level} (%{thread}) [%{position}] %{content}"
    target_prefix: ""
    ignore_failure: true
    overwrite_keys: true

# queue and batch
queue.mem:
events: 1000000
flush.min_events: 100000
flush.timeout: 10s

# output
output.doris:
fenodes: [ "http://fehost1:http_port", "http://fehost2:http_port", "http://fehost3:http_port" ]
user: "your_username"
password: "your_password"
database: "your_db"
table: "your_table"
# output string format
codec_format_string: '{"ts": "%{[day]} %{[time]}", "host": "%{[agent][hostname]}", "path": "%{[log][file]
[path]}", "message": "%{[message]}"}'
headers:
    format: "json"
    read_json_by_line: "true"
    load_to_single_tablet: "true"

```

3. Run Filebeat according to the command below, collect logs, and output to Apache Doris.

```

chmod +x filebeat-doris-2.1.1
./filebeat-doris-2.1.1 -c filebeat_demo.yml

```

For more information about Filebeat, refer to [Beats Doris Output Plugin](#).

Integrating Kafka

Write JSON formatted logs to Kafka's message queue, create a Kafka Routine Load, and allow Apache Doris to actively pull data from Kafka.

You can refer to the example below, where property.* represents Librdkafka client-related configurations and needs to be adjusted according to the actual Kafka cluster situation.

```

CREATE ROUTINE LOAD load_log_kafka ON log_db.log_table
COLUMNS(ts, clientip, request, status, size)
PROPERTIES (
    "max_batch_interval" = "60",
    "max_batch_rows" = "20000000",
    "max_batch_size" = "1073741824",
    "load_to_single_tablet" = "true",
    "format" = "json"
)
FROM KAFKA (
    "kafka_broker_list" = "host:port",
    "kafka_topic" = "log__topic",

```

```

"property.group.id" = "your_group_id",
"property.security.protocol"="SASL_PLAINTEXT",
"property.sasl.mechanism"="GSSAPI",
"property.sasl.kerberos.service.name"="kafka",
"property.sasl.kerberos.keytab"="/path/to/xxx.keytab",
"property.sasl.kerberos.principal"="<xxx@yyy.com>"
);
<br />SHOW ROUTINE LOAD;

```

For more information about Kafka, see [Routine Load](#).

Using customized programs to collect logs

In addition to integrating common log collectors, you can also customize programs to import log data into Apache Doris using the Stream Load HTTP API. Refer to the following code:

```

curl
--location-trusted
-u username:password
-H "format:json"
-H "read_json_by_line:true"
-H "load_to_single_tablet:true"
-H "timeout:600"
-T logfile.json
http://fe_host:fe_http_port/api/log_db/log_table/_stream_load

```

When using custom programs, pay attention to the following key points:

- Use Basic Auth for HTTP authentication, calculate using the command `echo -n 'username:password' | base64`.
- Set HTTP header “format:json” to specify the data format as JSON.
- Set HTTP header “read_json_by_line:true” to specify one JSON per line.
- Set HTTP header “load_to_single_tablet:true” to import data into one bucket at a time to reduce small file imports.
- It is recommended to write batches whose sizes are between 100MB to 1GB on the client side. For Apache Doris version 2.1 and higher, you need to reduce batch sizes on the client side through the Group Commit function.

Step 6: Query and analyze logs

Query logs

Apache Doris supports standard SQL, so you can connect to the cluster through MySQL client or JDBC to execute SQL for log queries.

Plain Text `mysql -h fe_host -P fe_mysql_port -u your_username -Dyour_db_name`

Here are 5 common SQL query commands for reference:

- View the latest 10 log entries

```
SELECT * FROM your_table_name ORDER BY ts DESC LIMIT 10;
```

- Query the latest 10 log entries with the host as 8.8.8.8

```
SELECT * FROM your_table_name WHERE host = '8.8.8.8' ORDER BY ts DESC LIMIT 10;
```

- Retrieve the latest 10 log entries with error or 404 in the request field. In the command below, MATCH_ANY is a full-text search SQL syntax used by Apache Doris for matching any keyword in the fields.

```
SELECT * FROM your_table_name WHERE message **MATCH_ANY** 'error 404'  
ORDER BY ts DESC LIMIT 10;
```

- Retrieve the latest 10 log entries with image and faq in the request field. In the command below, MATCH_ALL is a full-text search SQL syntax used by Apache Doris for matching all keywords in the fields.

```
SELECT * FROM your_table_name WHERE message **MATCH_ALL** 'image faq'  
ORDER BY ts DESC LIMIT 10;
```

- Retrieve the latest 10 entries with image and faq in the request field. In the following command, MATCH_PHRASE is a full-text search SQL syntax used by Apache Doris for matching all keywords in the fields and requiring consistent order. In the example below, a image faq b can match, but a faq image b cannot match because the order of image and faq does not match the syntax.

```
SELECT * FROM your_table_name WHERE message **MATCH_PHRASE** 'image faq'  
ORDER BY ts DESC LIMIT 10;
```

Analyze logs visually

Some third-party vendors offer visual log analysis development platforms based on Apache Doris, which include a log search and analysis interface similar to Kibana Discover. These platforms provide an intuitive and user-friendly exploratory log analysis interaction.

WebUI

- Support for full-text search and SQL modes
- Support for selecting query log timeframes with time boxes and histograms
- Display of detailed log information, expandable into JSON or tables
- Interactive clicking to add and remove filter conditions in the log data context
- Display of top field values in search results for finding anomalies and further drilling down for analysis

Please contact dev@doris.apache.org to find more.

CSV

This document explains how to load CSV format data files into Doris. Doris supports flexible CSV format configuration, including custom delimiters, field enclosures, and provides various loading methods to meet data loading requirements in different scenarios.

Loading Methods

Doris supports the following methods to load CSV format data:

- [Stream Load](#)
- [Broker Load](#)
- [Routine Load](#)
- [MySQL Load](#)
- [INSERT INTO FROM S3 TVF](#)
- [INSERT INTO FROM HDFS TVF](#)

Parameter Configuration

Parameter Support

The following table lists the CSV format parameters supported by various loading methods:

Parameter	Default Value	Stream Load	Broker Load	Routine Load	MySQL Load	TVF
Line Delimiter	\n	line_delimiter	LINES TERMINATED BY	Not supported	LINES TERMINATED BY	line_d elimit er
Column Delimiter	\t	column_separator	COLUMNS TERMINATED BY	COLUMNS TERMINATED BY	COLUMNS TERMINATED BY	colum n_sep arator
Enclosure	None	enclose	PROPERTIES.enclo se	PROPERTIES.enclo se	PROPERTIES.en close	enclo se
Escape Character	\	escape	PROPERTIES.esca pe	PROPERTIES.esca pe	PROPERTIES.es cape	escap e

Note

1. Stream Load: Parameters are specified directly through HTTP Headers, e.g., -H "line_delimiter:\n"
2. Broker Load: Parameters are specified in SQL statements, where:
 - Delimiters are specified through COLUMNS TERMINATED BY, LINES TERMINATED BY
 - Other parameters are specified through PROPERTIES, e.g., PROPERTIES("compress_type"="gz")
3. Routine Load: Parameters are specified in SQL statements, where:
 - Delimiters are specified through COLUMNS TERMINATED BY
 - Other parameters are specified through PROPERTIES, e.g., PROPERTIES("enclose"="\\"")
4. MySQL Load: Parameters are specified in SQL statements, where:
 - Delimiters are specified through LINES TERMINATED BY, COLUMNS TERMINATED BY
 - Other parameters are specified through PROPERTIES, e.g., PROPERTIES("escape"="\\"")
5. TVF: Parameters are specified in TVF statements, e.g., S3("line_delimiter"="\n")

Parameter Description

Line Delimiter

- Purpose: Specifies the line break character in the data file
- Default Value: \n
- Features: Supports multiple characters combination as line break
- Use Cases and Examples:
 - Linux/Unix System Files:

```
Data File:
John,25\n
Mary,30\n

Parameter Setting:
line_delimiter: \n (default value, can be omitted)
```

- Windows System Files:

```
Data File:
John,25\r\n
Mary,30\r\n

Parameter Setting:
line_delimiter: \r\n
```

- Special Program Generated Files:

```
Data File:
John,25\r
Mary,30\r
```

```
Parameter Setting:  
line_delimiter: \r
```

- Custom Multi-character Delimiter:

```
Data File:  
John,25||  
Mary,30||  
  
Parameter Setting:  
line_delimiter: ||
```

Column Delimiter

- Purpose: Specifies the column delimiter in the data file
- Default Value: \t (tab)
- Features:
 - Supports visible and invisible characters
 - Supports multiple character combinations
 - Invisible characters need to use hex representation with \x prefix
- Special Handling for MySQL Protocol:
 - Invisible characters need an extra backslash
 - For example, Hive's \x01 needs to be written as \\x01 in Broker Load
- Use Cases and Examples:
 - Common Visible Characters:

```
Data File:  
John,25,New York  
Mary,30,Los Angeles  
  
Parameter Setting:  
column_separator: ,
```

- Tab (Default):

```
Data File:  
John    25    New York  
Mary    30    Los Angeles  
  
Parameter Setting:  
column_separator: \t (default value, can be omitted)
```

- Hive Files (Stream Load):

```
Data File:  
John\x0125\x01New York  
Mary\x0130\x01Los Angeles  
  
Parameter Setting:  
column_separator: \x01
```

- Hive Files (Broker Load):

```
Data File:
John\x0125\x01New York
Mary\x0130\x01Los Angeles

Parameter Setting:
PROPERTIES("column_separator"="\x01")
```

- Multi-character Delimiter:

```
Data File:
John||25||New York
Mary||30||Los Angeles

Parameter Setting:
column_separator: ||
```

Enclosure

- Purpose: Protects fields containing special characters from being incorrectly parsed
- Limitation: Only supports single-byte characters
- Common Characters:
 - Single quote: '
 - Double quote: ''
- Use Cases and Examples:
 - Field Contains Column Delimiter:

```
Data: a,'b,c',d
Column Delimiter: ,
Enclosure: '
Parsing Result: 3 fields [a] [b,c] [d]
```

- Field Contains Line Delimiter:

```
Data: a,'b\nc',d
Column Delimiter: ,
Enclosure: '
Parsing Result: 3 fields [a] [b\nc] [d]
```

- Field Contains Both Column and Line Delimiters:

```
Data: a,'b,c\nd,e',f
Column Delimiter: ,
Enclosure: '
Parsing Result: 3 fields [a] [b,c\nd,e] [f]
```

Escape Character

- Purpose: Escapes characters in fields that are the same as the enclosure character

- Limitation: Only supports single-byte characters, default is \
- Use Cases and Examples:
 - Field Contains Enclosure Character:

```
Data: a,'b,\"c',d
Column Delimiter: ,
Enclosure: '
Escape Character: \
Parsing Result: 3 fields [a] [b,'c] [d]
```

- Field Contains Multiple Enclosure Characters:

```
Data: a,"b,\"c\"d",e
Column Delimiter: ,
Enclosure: "
Escape Character: \
Parsing Result: 3 fields [a] [b,"c"d] [e]
```

- Field Contains Escape Character Itself:

```
Data: a,'b\\c',d
Column Delimiter: ,
Enclosure: '
Escape Character: \
Parsing Result: 3 fields [a] [b\c] [d]
```

Skip Lines

- Purpose: Skips the first few lines of the CSV file
- Type: Integer
- Default Value: 0
- Special Note:
 - When format is csv_with_names, the system automatically skips the first line (column names), ignoring the skip_lines parameter
 - When format is csv_with_names_and_types, the system automatically skips the first two lines (column names and types), ignoring the skip_lines parameter
- Use Cases and Examples:
 - Skip Title Line:

```
Data File:
Name,Age,City
John,25,New York
Mary,30,Los Angeles

Parameter Setting:
skip_lines: 1
Result: Skip title line, load subsequent data
```

- Skip Comment Lines:

```
Data File:
# User Information Table
# Created Time: 2024-01-01
John,25,New York
Mary,30,Los Angeles

Parameter Setting:
skip_lines: 2
Result: Skip comment lines, load subsequent data
```

- Use csv_with_names Format:

```
Data File:
name,age,city
John,25,New York
Mary,30,Los Angeles

Parameter Setting:
format: csv_with_names
Result: System automatically skips the first line of column names
```

- Use csv_with_names_and_types Format:

```
Data File:
name,age,city
string,int,string
John,25,New York
Mary,30,Los Angeles

Parameter Setting:
format: csv_with_names_and_types
Result: System automatically skips the first two lines of column names and types
```

Trim Double Quotes

- Purpose: Trims the outermost double quotes from each field in the CSV file
- Type: Boolean
- Default Value: false
- Use Cases and Examples:

- Trim Double Quotes:

```
Data File:
"John","25","New York"
"Mary","30","Los Angeles"

Parameter Setting:
trim_double_quotes: true
Result:
John,25,New York
Mary,30,Los Angeles
```

Compression Format

- Purpose: Specifies the compression format of the data file
- Type: String, ignoring case
- Default Value: plain
- Supported Compression Formats:
 - plain: No compression (default)
 - bz2: BZIP2 compression
 - deflate: DEFLATE compression
 - gz: GZIP compression
 - lz4: LZ4 Frame format compression
 - lz4_block: LZ4 Block format compression
 - lzo: LZO compression
 - lzop: LZOP compression
 - snappy_block: SNAPPY Block format compression
- Note:
 - tar is a file packaging format, not a compression format, so it is not supported
 - If you need to use tar packaged files, please unpack them first before loading

Usage Examples

This section demonstrates the usage of CSV format in different loading methods.

Stream Load

```
# Specify delimiter
curl --location-trusted -u root: \
  -H "column_separator:," \
  -H "line_delimiter:\n" \
  -T example.csv \
  http://<fe_host>:<fe_http_port>/api/test_db/test_table/_stream_load

# Handle quoted data
curl --location-trusted -u root: \
  -H "column_separator:," \
  -H "enclose:\"\"\" \" \
  -T example.csv \
  http://<fe_host>:<fe_http_port>/api/test_db/test_table/_stream_load

# Load compressed file
curl --location-trusted -u root: \
  -H "compress_type:gz" \
  -T example.csv.gz \
  http://<fe_host>:<fe_http_port>/api/test_db/test_table/_stream_load
```

Broker Load

```
-- Specify delimiter
LOAD LABEL test_db.test_label
(
    DATA INFILE("s3://bucket/example.csv")
    INTO TABLE test_table
```

```

    COLUMNS TERMINATED BY ","
    LINES TERMINATED BY "\n"
    ...
);

-- Handle quoted data
LOAD LABEL test_db.test_label
(
    DATA INFILE("s3://bucket/example.csv")
    INTO TABLE test_table
    COLUMNS TERMINATED BY ","
    LINES TERMINATED BY "\n"
    PROPERTIES
    (
        "enclose" = "\"",
        "escape" = "\\"
    )
    ...
);

-- Load compressed file
LOAD LABEL test_db.test_label
(
    DATA INFILE("s3://bucket/example.csv.gz")
    INTO TABLE test_table
    COLUMNS TERMINATED BY ","
    LINES TERMINATED BY "\n"
    PROPERTIES
    (
        "compress_type" = "gz"
    )
    ...
);

```

Routine Load

```

-- Specify delimiter
CREATE ROUTINE LOAD test_db.test_job ON test_table
COLUMNS TERMINATED BY ","
FROM KAFKA
(
    ...
);

-- Handle quoted data
CREATE ROUTINE LOAD test_db.test_job ON test_table
COLUMNS TERMINATED BY ","
PROPERTIES
(
    "enclose" = "\"",
    "escape" = "\\"
)
FROM KAFKA
(
    ...
);

```

MySQL Load

```
-- Specify delimiter
LOAD DATA LOCAL INFILE 'example.csv'
INTO TABLE test_table
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n';

-- Handle quoted data
LOAD DATA LOCAL INFILE 'example.csv'
INTO TABLE test_table
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n'
PROPERTIES
(
    "enclose" = "\"",
    "escape" = "\\"
);

-- Skip table header
LOAD DATA LOCAL INFILE 'example.csv'
INTO TABLE test_table
COLUMNS TERMINATED BY ','
LINES TERMINATED BY '\n'
IGNORE 1 LINES;
```

TVF Load

```sql – Specify delimiter INSERT INTO test\_table SELECT \* FROM S3 ( "path" = "s3://bucket/example.csv",  
"column\_separator" = ",", "line\_delimiter" = "\n", ... );

– Handle quoted data INSERT INTO test\_table SELECT \* FROM S3 ( "path" = "s3://bucket/example.csv",  
"column\_separator" = ",", "enclose" = "\"", "escape" = "\\", ... );

– Load compressed file INSERT INTO test\_table SELECT \* FROM S3 ( "path" = "s3://bucket/example.csv.gz",  
"column\_separator" = ",", "line\_delimiter" = "\n", "compress\_type" = "gz", ... );

# JSON | File Format

---

This document explains how to load JSON format data files into Doris. Doris supports loading standard JSON format data and can flexibly handle different JSON data structures through parameter configuration, supporting field extraction from JSON data and handling nested structures.

## Loading Methods

The following loading methods support JSON format data:

- [Stream Load](#)
- [Broker Load](#)
- [Routine Load](#)
- [INSERT INTO FROM S3 TVF](#)
- [INSERT INTO FROM HDFS TVF](#)

## Supported JSON Formats

Doris supports the following three JSON formats:

### Multiple Rows Represented as Array

Suitable for batch loading multiple rows of data, requirements: - Root node must be an array - Each element in the array is an object representing a row of data - Must set `strip_outer_array=true`

Example data:

```
[
 {"id": 123, "city": "beijing"},
 {"id": 456, "city": "shanghai"}
]

// Supports nested structures
[
 {"id": 123, "city": {"name": "beijing", "region": "haidian"}},
 {"id": 456, "city": {"name": "beijing", "region": "chaoyang"}}
]
```

### Single Row Represented as Object

Suitable for loading single row data, requirements: - Root node must be an object - The entire object represents one row of data

Example data:

```
{"id": 123, "city": "beijing"}
```

```
// Supports nested structures
{"id": 123, "city": {"name": "beijing", "region": "haidian"}}
```

## Note

Typically used with Routine Load method, such as single messages in Kafka.

## Multiple Object Rows Separated by Delimiter

Suitable for batch loading multiple rows of data, requirements: - Each line is a complete JSON object - Must set `read_json_by_line=true` - Line delimiter can be specified using `line_delimiter` parameter, default is `\n`

Example data:

```
{"id": 123, "city": "beijing"}
{"id": 456, "city": "shanghai"}
```

## Parameter Configuration

### Parameter Support

The following table lists the JSON format parameters supported by various loading methods:

| Parameter          | Default Value | Stream Load       | Broker Load                  | Routine Load                 | TVF                             |
|--------------------|---------------|-------------------|------------------------------|------------------------------|---------------------------------|
| json paths         | None          | jsonpaths         | properties.jsonpaths         | properties.jsonpaths         | jsonpaths                       |
| json root          | None          | json_root         | properties.json_root         | properties.json_root         | json_root                       |
| strip outer array  | false         | strip_outer_array | properties.strip_outer_array | properties.strip_outer_array | strip_outer_array               |
| read json by line  | false         | read_json_by_line | Always true                  | Not supported                | read_json_by_line, default true |
| fuzzy parse        | false         | fuzzy_parse       | properties.fuzzy_parse       | Not supported                | fuzzy_parse                     |
| num as string      | false         | num_as_string     | properties.num_as_string     | properties.num_as_string     | num_as_string                   |
| compression format | plain         | Not Supported     | PROPERTIES.compression_type  | Not supported                | compression_type                |

## Note

1. Stream Load: Parameters are specified directly through HTTP Headers, e.g., `-H "jsonpaths: $.data"`
2. Broker Load: Parameters are specified through `PROPERTIES`, e.g., `PROPERTIES("jsonpaths"="$.data")`
3. Routine Load: Parameters are specified through `PROPERTIES`, e.g., `PROPERTIES("jsonpaths"="$.data")`
4. TVF: Parameters are specified in TVF statements, e.g., `S3("jsonpaths"="$.data")`
5. If you need to load the JSON object at the root node of a JSON file, the jsonpaths should be specified as `$.`, e.g., `PROPERTIES("jsonpaths"="$.")`

## Parameter Description

### JSON Path

- Purpose: Specifies how to extract fields from JSON data
- Type: String array
- Default Value: None, defaults to matching column names
- Usage Examples:

```
-- Basic usage
["$id", "$city"]

-- Nested structures
["$id", "$info.city", "$data[0].name"]
```

### JSON Root

- Purpose: Specifies the parsing starting point for JSON data
- Type: String
- Default Value: None, defaults to parsing from root node
- Usage Example:

```
-- Original data
{
 "data": {
 "id": 123,
 "city": "beijing"
 }
}

-- Set json_root
json_root = $.data
```

## Strip Outer Array

- Purpose: Specifies whether to remove the outermost array structure
- Type: Boolean
- Default Value: false
- Usage Example:

```
-- Original data
[
 {"id": 1, "city": "beijing"},
 {"id": 2, "city": "shanghai"}
]

-- Set strip_outer_array=true
```

## Read JSON By Line

- Purpose: Specifies whether to read JSON data line by line
- Type: Boolean
- Default Value: false
- Usage Example:

```
-- Original data (one complete JSON object per line)
{"id": 1, "city": "beijing"}
{"id": 2, "city": "shanghai"}

-- Set read_json_by_line=true
```

## Fuzzy Parse

- Purpose: Accelerates JSON data loading efficiency
- Type: Boolean
- Default Value: false
- Limitations:
  - Field order in each row of the Array must be identical
  - Usually used with strip\_outer\_array
- Performance: Can improve loading efficiency by 3-5 times

## Num As String

- Purpose: Specifies whether to parse JSON numeric types as strings
- Type: Boolean
- Default Value: false

- Use Cases:
  - Handling numbers outside numeric range
  - Avoiding numeric precision loss
- Usage Example:

```
-- Original data
{
 "id": "12345678901234567890",
 "price": "99999999.999999"
}
-- Set num_as_string=true, price field will be parsed as string
```

## Relationship between JSON Path and Columns

During data loading, JSON Path and Columns serve different responsibilities:

**JSON Path:** Defines data extraction rules - Extracts fields from JSON data according to specified paths - Extracted fields are reordered according to the order defined in JSON Path

**Columns:** Defines data mapping rules - Maps extracted fields to target table columns - Can perform column reordering and transformation

These two parameters are processed serially: first, JSON Path extracts fields from source data and forms an ordered dataset, then Columns maps these data to table columns. If Columns is not specified, extracted fields will be mapped directly according to table column order.

## Usage Examples

### Using JSON Path Only

Table structure and data:

```
-- Table structure
CREATE TABLE example_table (
 k2 int,
 k1 int
);

-- JSON data
{"k1": 1, "k2": 2}
```

Load command:

```
curl -v ... -H "format: json" \
-H "jsonpaths: [\"$.k2\", \"$.k1\"]" \
-T example.json \
http://<fe_host>:<fe_http_port>/api/db_name/table_name/_stream_load
```

Load result:

| k1 | k2 |
|----|----|
| 2  | 1  |

## Using JSON Path + Columns

Using the same table structure and data, adding columns parameter:

Load command:

```
curl -v ... -H "format: json" \
 -H "jsonpaths: [\"$.k2\", \"$.k1\"]" \
 -H "columns: k2, k1" \
 -T example.json \
 http://<fe_host>:<fe_http_port>/api/db_name/table_name/_stream_load
```

Load result:

| k1 | k2 |
|----|----|
| 1  | 2  |

## Field Reuse

Table structure and data:

```
-- Table structure
CREATE TABLE example_table (
 k2 int,
 k1 int,
 k1_copy int
);

-- JSON data
{"k1": 1, "k2": 2}
```

Load command:

```
curl -v ... -H "format: json" \
 -H "jsonpaths: [\"$.k2\", \"$.k1\", \"$.k1\"]" \
 -H "columns: k2, k1, k1_copy" \
 -T example.json \
 http://<fe_host>:<fe_http_port>/api/db_name/table_name/_stream_load
```

Load result:

| k2 | k1 | k1_copy |
|----|----|---------|
| 2  | 1  | 1       |

## Nested Field Mapping

Table structure and data:

```
-- Table structure
CREATE TABLE example_table (
 k2 int,
 k1 int,
 k1_nested1 int,
 k1_nested2 int
);

-- JSON data
{
 "k1": 1,
 "k2": 2,
 "k3": {
 "k1": 31,
 "k1_nested": {
 "k1": 32
 }
 }
}
```

Load command:

```
curl -v ... -H "format: json" \
-H "jsonpaths: [\"$.k2\", \"$.k1\", \"$.k3.k1\", \"$.k3.k1_nested.k1\"]" \
-H "columns: k2, k1, k1_nested1, k1_nested2" \
-T example.json \
http://<fe_host>:<fe_http_port>/api/db_name/table_name/_stream_load
```

Load result:

| k2 | k1 | k1_nested1 | k1_nested2 |
|----|----|------------|------------|
| 2  | 1  | 31         | 32         |

## Usage Examples

This section demonstrates the usage of JSON format in different loading methods.

## Stream Load

```
Using JSON Path
curl --location-trusted -u <user>:<passwd> \
 -H "format: json" \
 -H "jsonpaths: [\"$.id\", \"$.city\"]" \
 -T example.json \
 http://<fe_host>:<fe_http_port>/api/example_db/example_table/_stream_load

Specifying JSON root
curl --location-trusted -u <user>:<passwd> \
 -H "format: json" \
 -H "json_root: $.events" \
 -T example.json \
 http://<fe_host>:<fe_http_port>/api/example_db/example_table/_stream_load

Reading JSON by line
curl --location-trusted -u <user>:<passwd> \
 -H "format: json" \
 -H "read_json_by_line: true" \
 -T example.json \
 http://<fe_host>:<fe_http_port>/api/example_db/example_table/_stream_load
```

## Broker Load

```
-- Using JSON Path
LOAD LABEL example_db.example_label
(
 DATA INFILE("s3://bucket/path/example.json")
 INTO TABLE example_table
 FORMAT AS "json"
 PROPERTIES
 (
 "jsonpaths" = [\"$.id\", \"$.city\"]
)
)
WITH S3
(
 ...
);

-- Specifying JSON root
LOAD LABEL example_db.example_label
(
 DATA INFILE("s3://bucket/path/example.json")
 INTO TABLE example_table
 FORMAT AS "json"
 PROPERTIES
 (
 "json_root" = "$.events"
)
)
WITH S3
(
 ...
);
```

## Routine Load

```
-- Using JSON Path
CREATE ROUTINE LOAD example_db.example_job ON example_table
PROPERTIES
(
 "format" = "json",
 "jsonpaths" = "["$.id\", \"$.city\"]"
)
FROM KAFKA
(
 ...
);
```

## TVF Load

``sql – Using JSON Path INSERT INTO example\_table SELECT \* FROM S3 ( "path" =  
"s3://bucket/example.json", "format" = "json", "jsonpaths" = "["\$.id\", \"\$.city\"]", ... );

– Specifying JSON root INSERT INTO example\_table SELECT \* FROM S3 ( "path" =  
"s3://bucket/example.json", "format" = "json", "json\_root" = "\$.events", ... );

# Parquet | File Format

---

## Parquet

This document explains how to load Parquet format data files in Doris.

## Supported Loading Methods

The following loading methods support Parquet format data:

- [Stream Load](#)
- [Broker Load](#)
- [INSERT INTO FROM S3 TVF](#)
- [INSERT INTO FROM HDFS TVF](#)

## Usage Examples

This section demonstrates the usage of Parquet format in different loading methods.

### Stream Load

```
curl --location-trusted -u <user>:<passwd> \
-H "format: parquet" \
-T example.parquet \
http://<fe_host>:<fe_http_port>/api/example_db/example_table/_stream_load
```

### Broker Load

```
LOAD LABEL example_db.example_label
(
 DATA INFILE("s3://bucket/example.parquet")
 INTO TABLE example_table
 FORMAT AS "parquet"
)
WITH S3
(
 ...
);
```

### TVF Load

```
```sql INSERT INTO example_table SELECT * FROM S3 ( "path" = "s3://bucket/example.parquet", "format" =  
"parquet", ... );
```

ORC | File Format

ORC

This document explains how to load ORC format data files in Doris.

Supported Loading Methods

The following loading methods support ORC format data:

- [Stream Load](#)
- [Broker Load](#)
- [INSERT INTO FROM S3 TVF](#)
- [INSERT INTO FROM HDFS TVF](#)

Usage Examples

This section demonstrates the usage of ORC format in different loading methods.

Stream Load

```
curl --location-trusted -u <user>:<passwd> \  
  -H "format: orc" \  
  -T example.orc \  
  http://<fe_host>:<fe_http_port>/api/example_db/example_table/_stream_load
```

Broker Load

```
LOAD LABEL example_db.example_label  
(  
  DATA INFILE("s3://bucket/example.orc")  
  INTO TABLE example_table  
  FORMAT AS "orc"  
)  
WITH S3  
(  
  ...  
);
```

TVF Load

```
```sql INSERT INTO example_table SELECT * FROM S3 ( "path" = "s3://bucket/example.orc", "format" = "orc",  
...);
```

# ARRAY | Complex Types

## ARRAY

ARRAY<T> An array of T-type items, it cannot be used as a key column.

- Before version 2.0, it was only supported in the Duplicate model table.
- Starting from version 2.0, it is supported in the non-key columns of the Unique model table.

T-type could be any of:

```
BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, LARGEINT, FLOAT, DOUBLE, DECIMAL, DATE,
DATEV2, DATETIME, DATETIMEV2, CHAR, VARCHAR, STRING
```

## CSV format import

### Step 1: Prepare the data

Create the following csv file: test\_array.csv The separator is | instead of comma to distinguish it from the comma in array.

```
1|[1,2,3,4,5]
2|[6,7,8]
3|[]
4|null
```

### Step 2: Create a table in the database

```
CREATE TABLE `array_test` (
 `id` INT NOT NULL,
 `c_array` ARRAY<INT> NULL
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "column_separator:|" \
 -H "columns: id, c_array" \
 -T "test_array.csv" \
 http://localhost:8040/api/testdb/array_test/_stream_load
```

## Step 4: Check the imported data

```
mysql> SELECT * FROM array_test;
+-----+-----+
| id | c_array |
+-----+-----+
| 1 | [1, 2, 3, 4, 5] |
| 2 | [6, 7, 8] |
| 3 | [] |
| 4 | NULL |
+-----+-----+
4 rows in set (0.01 sec)
```

## JSON format import

### Step 1: Prepare the data

Create the following JSON file, test\_array.json

```
[
 {"id":1, "c_array":[1,2,3,4,5]},
 {"id":2, "c_array":[6,7,8]},
 {"id":3, "c_array":[]},
 {"id":4, "c_array":null}
]
```

### Step 2: Create a table in the database

```
CREATE TABLE `array_test` (
 `id` INT NOT NULL,
 `c_array` ARRAY<INT> NULL
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "format:json" \
 -H "columns: id, c_array" \
 -H "strip_outer_array:true" \
 -T "test_array.json" \
 http://localhost:8040/api/testdb/array_test/_stream_load
```

## Step 4: Check the imported data

```
mysql> SELECT * FROM array_test;
+-----+-----+
```

id	c_array
1	[1, 2, 3, 4, 5]
2	[6, 7, 8]
3	[]
4	NULL

4 rows in set (0.01 sec)

# MAP | Complex Types

## MAP

MAP<K, V> A Map of K, V items, it cannot be used as a key column. Now MAP can only be used in Duplicate and Unique Model Tables.

K,V could be any of:

```
BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, LARGEINT, FLOAT, DOUBLE, DECIMAL, DECIMALV3, DATE,
DATEV2, DATETIME, DATETIMEV2, CHAR, VARCHAR, STRING
```

## CSV format import

### Step 1: Prepare the data

Create the following csv file: test\_map.csv The separator is | instead of comma to distinguish it from the comma in map.

```
1|{"Emily":101,"age":25}
2|{"Benjamin":102}
3|{}
4|null
```

### Step 2: Create a table in the database

```
CREATE TABLE map_test (
 id INT NOT NULL,
 c_map MAP<STRING, INT> NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "column_separator:|" \
 -H "columns: id, c_map" \
 -T "test_map.csv" \
 http://localhost:8040/api/testdb/map_test/_stream_load
```

## Step 4: Check the imported data

```
mysql> SELECT * FROM map_test;
+-----+-----+
| id | c_map |
+-----+-----+
| 1 | {"Emily":101, "age":25} |
| 2 | {"Benjamin":102} |
| 3 | {} |
| 4 | NULL |
+-----+-----+
4 rows in set (0.01 sec)
```

## JSON format import

### Step 1: Prepare the data

Create the following JSON file, test\_map.json

```
[
 {"id":1, "c_map":{"Emily":101, "age":25}},
 {"id":2, "c_map":{"Benjamin":102}},
 {"id":3, "c_map":{}},
 {"id":4, "c_map":null}
]
```

### Step 2: Create a table in the database

```
CREATE TABLE map_test (
 id INT NOT NULL,
 c_map MAP<STRING, INT> NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "format:json" \
 -H "columns: id, c_map" \
 -H "strip_outer_array:true" \
 -T "test_map.json" \
 http://localhost:8040/api/testdb/map_test/_stream_load
```

## Step 4: Check the imported data

```
mysql> SELECT * FROM map_test;
+-----+-----+
```

id	c_map
1	{"Emily":101, "age":25}
2	{"Benjamin":102}
3	{}
4	NULL

4 rows in set (0.01 sec)

# STRUCT | Complex Types

## STRUCT

STRUCT<field\_name:field\_type [COMMENT 'comment\_string'], ... > Represents value with structure described by multiple fields, which can be viewed as a collection of multiple columns.

- It cannot be used as a Key column. Now STRUCT can only be used in Duplicate Model Tables.
- The names and number of Fields in a Struct are fixed and always Nullable, and a Field typically consists of the following parts.
  - field\_name: Identifier naming the field, non repeatable.
  - field\_type: A data type.
  - COMMENT: An optional string describing the field. (currently not supported)

The currently supported types are:

```
BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, LARGEINT, FLOAT, DOUBLE, DECIMAL, DECIMALV3, DATE,
DATEV2, DATETIME, DATETIMEV2, CHAR, VARCHAR, STRING
```

## CSV format import

### Step 1: Prepare the data

Create the following csv file: test\_struct.csv The separator is | instead of comma to distinguish it from the comma in struct.

```
1|{10, 3.14, "Emily"}
2|{4, 1.5, null}
3|{7, null, "Benjamin"}
4|{}
5|null
```

### Step 2: Create a table in the database

```
CREATE TABLE struct_test (
 id INT NOT NULL,
 c_struct STRUCT<f1:INT,f2:FLOAT,f3:STRING> NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "column_separator:|" \
 -H "columns: id, c_struct" \
 -T "test_struct.csv" \
 http://localhost:8040/api/testdb/struct_test/_stream_load
```

### Step 4: Check the imported data

```
mysql> SELECT * FROM struct_test;
+-----+-----+
| id | c_struct |
+-----+-----+
| 1 | {"f1":10, "f2":3.14, "f3":"Emily"} |
| 2 | {"f1":4, "f2":1.5, "f3":null} |
| 3 | {"f1":7, "f2":null, "f3":"Benjamin"} |
| 4 | {"f1":null, "f2":null, "f3":null} |
| 5 | NULL |
+-----+-----+
5 rows in set (0.01 sec)
```

## JSON format import

### Step 1: Prepare the data

Create the following JSON file, test\_struct.json

```
[
 {"id":1, "c_struct":{"f1":10, "f2":3.14, "f3":"Emily"}},
 {"id":2, "c_struct":{"f1":4, "f2":1.5, "f3":null}},
 {"id":3, "c_struct":{"f1":7, "f2":null, "f3":"Benjamin"}},
 {"id":4, "c_struct":{}},
 {"id":5, "c_struct":null}
]
```

### Step 2: Create a table in the database

```
CREATE TABLE struct_test (
 id INT NOT NULL,
 c_struct STRUCT<f1:INT,f2:FLOAT,f3:STRING> NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "format:json" \
 -H "columns: id, c_struct" \
 -H "strip_outer_array:true" \
 -T "test_struct.json" \
 http://localhost:8040/api/testdb/struct_test/_stream_load
```

### Step 4: Check the imported data

```
mysql> SELECT * FROM struct_test;
+-----+-----+
| id | c_struct |
+-----+-----+
| 1 | {"f1":10, "f2":3.14, "f3":"Emily"} |
| 2 | {"f1":4, "f2":1.5, "f3":null} |
| 3 | {"f1":7, "f2":null, "f3":"Benjamin"} |
| 4 | {"f1":null, "f2":null, "f3":null} |
| 5 | NULL |
+-----+-----+
5 rows in set (0.00 sec)
```

# JSON | Complex Types

---

## JSON

The JSON data type stores JSON data efficiently in a binary format and allows access to its internal fields through JSON functions.

By default, it supports up to 1048576 bytes (1MB), and can be increased up to 2147483643 bytes (2GB). This can be adjusted via the `string_type_length_soft_limit_bytes` configuration.

Compared to storing JSON strings in a regular STRING type, the JSON type has two main advantages:

JSON format validation during data insertion. More efficient binary storage format, enabling faster access to JSON internal fields using functions like `json_extract`, compared to `get_json_xx` functions. Note: In version 1.2.x, the JSON type was named JSONB. To maintain compatibility with MySQL, it was renamed to JSON starting from version 2.0.0. Older tables can still use the previous name.

## CSV format import

### Step 1: Prepare the data

Create the following csv file: `test_json.csv` The separator is `|` instead of comma to distinguish it from the comma in json.

```
1|{"name": "tom", "age": 35}
2|{"name": null, "age": 28}
3|{"name": "michael", "age": null}
4|{"name": null, "age": null}
5|null
```

### Step 2: Create a table in the database

```
CREATE TABLE json_test (
 id INT NOT NULL,
 c_json JSON NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root":"" \
 -H "column_separator:|" \
 -H "columns: id, c_json" \
```

```
-T "test_json.csv" \
http://localhost:8040/api/testdb/json_test/_stream_load
```

## Step 4: Check the imported data

```
SELECT * FROM json_test;
+-----+-----+
| id | c_json |
+-----+-----+
| 1 | {"name":"tom","age":35} |
| 2 | {"name":null,"age":28} |
| 3 | {"name":"michael","age":null} |
| 4 | {"name":null,"age":null} |
| 5 | null |
+-----+-----+
5 rows in set (0.01 sec)
```

## JSON format import

### Step 1: Prepare the data

Create the following JSON file, test\_json.json

```
[
 {"id": 1, "c_json": {"name": "tom", "age": 35}},
 {"id": 2, "c_json": {"name": null, "age": 28}},
 {"id": 3, "c_json": {"name": "michael", "age": null}},
 {"id": 4, "c_json": {"name": null, "age": null}},
 {"id": 5, "c_json": null}
]
```

### Step 2: Create a table in the database

```
CREATE TABLE json_test (
 id INT NOT NULL,
 c_json JSON NULL
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Step 3: Load data

```
curl --location-trusted \
 -u "root:" \
 -H "format:json" \
 -H "columns: id, c_json" \
 -H "strip_outer_array:true" \
 -T "test_json.json" \
 http://localhost:8040/api/testdb/json_test/_stream_load
```

#### Step 4: Check the imported data

```
mysql> SELECT * FROM json_test;
```

id	c_json
1	{"name":"tom","age":35}
2	{"name":null,"age":28}
3	{"name":"michael","age":null}
4	{"name":null,"age":null}
5	NULL

```
5 rows in set (0.01 sec)
```

# Bitmap

The BITMAP type can be used in Duplicate tables, Unique tables, and Aggregate tables, and can only be used as a Value type, not as a Key type. When using the BITMAP type in an Aggregate table, the table must be created with the aggregate type BITMAP\_UNION. Users do not need to specify length and default values. The length is controlled by the system based on the degree of data aggregation. For more documentation, refer to [Bitmap](#).

## Usage Example

### Step 1: Prepare Data

Create the following CSV file: test\_bitmap.csv

```
1|koga|17723
2|nijg|146285
3|lojn|347890
4|lofn|489871
5|jfin|545679
6|kon|676724
7|nhga|767689
8|nfubg|879878
9|huang|969798
10|buag|97997
```

### Step 2: Create Table in Database

```
CREATE TABLE testdb.test_bitmap(
 typ_id BIGINT NULL COMMENT "ID",
 hou VARCHAR(10) NULL COMMENT "one",
 arr BITMAP BITMAP_UNION NOT NULL COMMENT "two"
)
AGGREGATE KEY(typ_id,hou)
DISTRIBUTED BY HASH(typ_id,hou) BUCKETS 10;
```

### Step 3: Load Data

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "column_separator:|" \
-H "columns:typ_id,hou,arr,arr=to_bitmap(arr)" \
-T test_bitmap.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_bitmap/_stream_load
```

### Step 4: Check Loaded Data

```
mysql> select typ_id,hou,bitmap_to_string(arr) from testdb.test_bitmap;
+-----+-----+-----+
| typ_id | hou | bitmap_to_string(arr) |
```

```

+-----+
| 4 | lofn | 489871 |
| 6 | kon | 676724 |
| 9 | huang | 969798 |
| 3 | lojn | 347890 |
| 8 | nfubg | 879878 |
| 7 | nhga | 767689 |
| 1 | koga | 17723 |
| 2 | nijg | 146285 |
| 5 | jfin | 545679 |
| 10| buag | 97997 |
+-----+
10 rows in set (0.07 sec)

```

## Importing a Bitmap Containing Multiple Elements

The following demonstrates two methods for importing a bitmap column containing multiple elements using stream load. Users can choose the appropriate method based on their source file format.

### bitmap\_from\_string

When using `bitmap_from_string`, square brackets are not allowed in the `arr` column of the source file. Otherwise, it will be considered a data quality error.

```

1|koga|17,723
2|nijg|146,285
3|lojn|347,890
4|lofn|489,871
5|jfin|545,679
6|kon|676,724
7|nhga|767,689
8|nfubg|879,878
9|huang|969,798
10|buag|97,997

```

Command for stream load

```

curl --location-trusted -u <doris_user>:<doris_password> \
-H "column_separator:|" \
-H "columns:typ_id,hou,arr,arr=bitmap_from_string(arr)" \
-T test_bitmap.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_bitmap/_stream_load

```

### bitmap\_from\_array

When using `bitmap_from_array`, the source file can contain square brackets in the `arr` column. However, in stream load, the string type must first be cast to an array type before use. If the cast conversion is not applied, an error will occur due to the function signature not being found: `[ANALYSIS_ERROR]TStatus: errCode = 2, detailMessage = Does not support non-builtin functions, or function does not exist: bitmap_from_array(<slot 8>)`

```

1|koga|[17,723]
2|nijg|[146,285]
3|lojn|[347,890]

```

```
4|lofn|[489,871]
5|jfin|[545,679]
6|kon|[676,724]
7|nhga|[767,689]
8|nfubg|[879,878]
9|huang|[969,798]
10|buag|[97,997]
```

## Command for stream load

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "column_separator:|" \
-H "columns:typ_id,hou,arr_str,arr=bitmap_from_array(cast(arr_str as array<int>))" \
-T test_bitmap.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_bitmap/_stream_load
```

# HLL

HLL is used for approximate deduplication and performs better than Count Distinct when dealing with large data volumes. The load of HLL needs to be combined with functions like `hll_hash`. For more documentation, refer to [HLL](#).

## Usage Example

### Step 1: Prepare Data

Create the following CSV file: `test_hll.csv`

```
1001|koga
1002|nijg
1003|lojn
1004|lofn
1005|jfin
1006|kon
1007|nhga
1008|nfubg
1009|huang
1010|buag
```

### Step 2: Create Table in Database

```
CREATE TABLE testdb.test_hll(
 typ_id BIGINT NULL COMMENT "ID",
 typ_name VARCHAR(10) NULL COMMENT "NAME",
 pv hll hll_union NOT NULL COMMENT "hll"
)
AGGREGATE KEY(typ_id,typ_name)
DISTRIBUTED BY HASH(typ_id) BUCKETS 10;
```

### Step 3: Load Data

```
curl --location-trusted -u <doris_user>:<doris_password> \
-H "column_separator:|" \
-H "columns:typ_id,typ_name,pv=hll_hash(typ_id)" \
-T test_hll.csv \
-XPUT http://<fe_ip>:<fe_http_port>/api/testdb/test_hll/_stream_load
```

### Step 4: Check Loaded Data

Use `hll_cardinality` to query:

```
``sql mysql> select typ_id,typ_name,hll_cardinality(pv) from testdb.test_hll; +-----+-----+-----+
| typ_id | typ_name | hll_cardinality(pv) | +-----+-----+-----+ | 1010 | buag | 1 | | 1002 | nijg | 1 | |
```

1001		koga		1			1008		nfubg		1			1005		jfin		1			1009		huang		1			1004		lofn		1			1007		nhga		1		
1003		lojn		1			1006		kon		1			+-----+-----+-----+ 10 rows in set (0.06 sec)																											

# Variant

---

The VARIANT type can store semi-structured JSON data, allowing for the storage of complex data structures that contain different data types (such as integers, strings, booleans, etc.) without the need to predefine specific columns in the table structure. This type is particularly suitable for handling complex nested structures that may change at any time. During the writing process, the VARIANT type can automatically infer the structure and type of the columns, dynamically merging the written schema, and storing the JSON keys and their corresponding values as columns and dynamic sub-columns. For more documentation, please refer to [VARIANT](#).

## Usage Limitations

Supports CSV and JSON formats.

## Loading CSV Format

### Step 1: Prepare Data

Create a CSV file named `test_variant.csv` with the following content:

```
14186154924|PushEvent|
{"avatar_url":"https://avatars.githubusercontent.com/u/282080?","display_login":"brianchandotcom","gravatar_id":"","id":282080,"login":"brianchandotcom","url":"https://api.github.com/users/brianchandotcom"}|
{"id":1920851,"name":"brianchandotcom/liferay-portal","url":"https://api.github.com/repos/brianchandotcom/liferay-portal"}|
{"before":"abb58cc0db673a0bd5190000d2ff9c53bb51d04d","commits":
[["","distinct_size":4,"head":"91edd3c8c98c214155191feb852831ec535580ba","push_id":6027092734,"ref":"refs/heads/master","size":4}|1|2020-11-14 02:00:00
```

### Step 2: Create Table in Database

Execute the following SQL statement to create the table:

```
CREATE TABLE IF NOT EXISTS testdb.test_variant (
 id BIGINT NOT NULL,
 type VARCHAR(30) NULL,
 actor VARIANT NULL,
 repo VARIANT NULL,
 payload VARIANT NULL,
 public BOOLEAN NULL,
 created_at DATETIME NULL,
 INDEX idx_payload (`payload`) USING INVERTED PROPERTIES("parser" = "english") COMMENT 'inverted index for payload'
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(id) BUCKETS 10
properties("replication_num" = "1");
```

### Step 3: Load Data

Using stream load as an example, use the following command to load data:

```
curl --location-trusted -u root: -T test_variant.csv -H "column_separator:|"
http://127.0.0.1:8030/api/testdb/test_variant/_stream_load
```

Example of load results:

```
{
 "TxnId": 12,
 "Label": "96cd6250-9c78-4a9f-b8b3-2b7cef0dd606",
 "Comment": "",
 "TwoPhaseCommit": "false",
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 1,
 "NumberLoadedRows": 1,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 660,
 "LoadTimeMs": 213,
 "BeginTxnTimeMs": 0,
 "StreamLoadPutTimeMs": 6,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 183,
 "ReceiveDataTimeMs": 14,
 "CommitAndPublishTimeMs": 20
}
```

### Step 4: Check Loaded Data

Use the following SQL query to check the loaded data:

```
mysql> select * from testdb.test_variant\G
***** 1. row *****
 id: 14186154924
 type: PushEvent
 actor:
{"avatar_url":"https://avatars.githubusercontent.com/u/282080?","display_login":"brianchandotcom","gravatar_id":"","id":282080,"login":"brianchandotcom","url":"https://api.github.com/users/brianchandotcom"}
 repo: {"id":1920851,"name":"brianchandotcom/liferay-portal","url":"https://api.github.com/repos/brianchandotcom/liferay-portal"}
 payload: {"before":"abb58cc0db673a0bd5190000d2ff9c53bb51d04d","commits":[""],"distinct_size":4,"head":"91edd3c8c98c214155191feb852831ec535580ba","push_id":6027092734,"ref":"refs/heads/master","size":4}
 public: 1
 created_at: 2020-11-14 02:00:00
```

## Loading JSON Format

### Step 1: Prepare Data

Create a JSON file named `test_variant.json` with the following content:

```
{
 "id": "14186154924",
 "type": "PushEvent",
 "actor": {
 "id": 282080,
 "login": "brianchandotcom",
 "display_login": "brianchandotcom",
 "gravatar_id": "",
 "url": "https://api.github.com/users/brianchandotcom",
 "avatar_url": "https://avatars.githubusercontent.com/u/282080?"
 },
 "repo": {
 "id": 1920851,
 "name": "brianchandotcom/liferay-portal",
 "url": "https://api.github.com/repos/brianchandotcom/liferay-portal"
 },
 "payload": {
 "push_id": 6027092734,
 "size": 4,
 "distinct_size": 4,
 "ref": "refs/heads/master",
 "head": "91edd3c8c98c214155191feb852831ec535580ba",
 "before": "abb58cc0db673a0bd5190000d2ff9c53bb51d04d",
 "commits": [
 [
 ""
]
],
 "public": true,
 "created_at": "2020-11-13T18:00:00Z"
 }
}
```

## Step 2: Create Table in Database

Execute the following SQL statement to create the table:

```
CREATE TABLE IF NOT EXISTS testdb.test_variant (
 id BIGINT NOT NULL,
 type VARCHAR(30) NULL,
 actor VARIANT NULL,
 repo VARIANT NULL,
 payload VARIANT NULL,
 public BOOLEAN NULL,
 created_at DATETIME NULL,
 INDEX idx_payload (`payload`) USING INVERTED PROPERTIES("parser" = "english") COMMENT 'inverted index for payload'
)
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(id) BUCKETS 10;
```

## Step 3: Load Data

Using stream load as an example, use the following command to load data:

```
curl --location-trusted -u root: -T test_variant.json -H "format:json"
http://127.0.0.1:8030/api/testdb/test_variant/_stream_load
```

Example of load results:

```
{
 "TxnId": 12,
 "Label": "96cd6250-9c78-4a9f-b8b3-2b7cef0dd606",
 "Comment": "",
 "TwoPhaseCommit": "false",
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 1,
 "NumberLoadedRows": 1,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 660,
 "LoadTimeMs": 213,
 "BeginTxnTimeMs": 0,
 "StreamLoadPutTimeMs": 6,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 183,
 "ReceiveDataTimeMs": 14,
 "CommitAndPublishTimeMs": 20
}
```

## Step 4: Check Loaded Data

Use the following SQL query to check the loaded data:

```
mysql> select * from testdb.test_variant\G
***** 1. row *****
 id: 14186154924
 type: PushEvent
 actor:
{"avatar_url":"https://avatars.githubusercontent.com/u/282080?","display_login":"brianchandotcom","gravatar_id":"","id":282080,"login":"brianchandotcom","url":"https://api.github.com/users/brianchandotcom"}
 repo: {"id":1920851,"name":"brianchandotcom/liferay-portal","url":"https://api.github.com/repos/brianchandotcom/liferay-portal"}
 payload: {"before":"abb58cc0db673a0bd5190000d2ff9c53bb51d04d","commits":[""],"distinct_size":4,"head":"91edd3c8c98c214155191feb852831ec535580ba","push_id":6027092734,"ref":"refs/heads/master","size":4}
 public: 1
 created_at: 2020-11-14 02:00:00
```

## Step 5: Check type inference

Running desc command to view schema information, sub-columns will automatically expand at the storage layer and undergo type inference.

```
mysql> desc test_variant;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| id | BIGINT | No | true | NULL | |
| type | VARCHAR(*) | Yes | false | NULL | NONE |
| actor | VARIANT | Yes | false | NULL | NONE |
| created_at | DATETIME | Yes | false | NULL | NONE |
| payload | VARIANT | Yes | false | NULL | NONE |
| public | BOOLEAN | Yes | false | NULL | NONE |
+-----+-----+-----+-----+-----+-----+
6 rows in set (0.07 sec)

mysql> set describe_extend_variant_column = true;
Query OK, 0 rows affected (0.01 sec)

mysql> desc test_variant;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| id | BIGINT | No | true | NULL | |
| type | VARCHAR(*) | Yes | false | NULL | NONE |
| actor | VARIANT | Yes | false | NULL | NONE |
| actor.avatar_url | TEXT | Yes | false | NULL | NONE |
| actor.display_login | TEXT | Yes | false | NULL | NONE |
| actor.id | INT | Yes | false | NULL | NONE |
| actor.login | TEXT | Yes | false | NULL | NONE |
| actor.url | TEXT | Yes | false | NULL | NONE |
| created_at | DATETIME | Yes | false | NULL | NONE |
| payload | VARIANT | Yes | false | NULL | NONE |
| payload.action | TEXT | Yes | false | NULL | NONE |
| payload.before | TEXT | Yes | false | NULL | NONE |
| payload.comment.author_association | TEXT | Yes | false | NULL | NONE |
| payload.comment.body | TEXT | Yes | false | NULL | NONE |
+-----+-----+-----+-----+-----+-----+
....
```

```
+-----+-----+-----+-----+-----+
406 rows in set (0.07 sec)
```

DESC can be used to specify partition and view the schema of a particular partition. The syntax is as follows:

```
DESCRIBE ${table_name} PARTITION ($partition_name);
```

# Handling Data Issues

When loading data, sometimes the types of data in the source and target columns don't match. The system tries to fix these mismatches, but problems like wrong types, too long fields, or wrong precision can cause errors.

To deal with these problems, Doris has two key settings:

- Strict Mode (strict\_mode): Decide if rows with errors should be removed.
- Max Filter Ratio (max\_filter\_ratio): Sets the highest allowed percentage of data that can be removed during loading.

This makes it easier to handle data loading problems and keeps data management strong and simple.

## Strict Mode

Strict mode serves two primary purposes: 1. Filtering out data rows where column type conversion fails during load 2. Restricting updates to existing columns only in partial column update scenarios

### Filtering Strategy for Column Type Conversion Failures

The system employs different strategies based on the strict mode setting:

- When strict mode is OFF: Fields that fail conversion are set to NULL, and rows containing these NULL values are loaded along with the correct data rows.
- When strict mode is ON: The system filters out rows with conversion failures and only loads correct data rows. Here, "conversion failure" specifically refers to cases where the original data is non-NULL but becomes NULL after column type conversion. Note that NULL values resulting from function calculations are not included in this type of conversion.
- Handling NULL values: Both correct and abnormal data rows may contain NULL values. If the target column is defined as NOT NULL, all rows containing NULL values will be filtered out.

#### 1. Example with TinyInt column type:

Original Data Type	Original Data Example	Value After TinyInt Conversion	Strict Mode	Result
NULL		NULL	ON/OFF	NULL
Non-NULL	"abc" or 2000	NULL	ON	Invalid (Filtered)
Non-NULL	"abc"	NULL	OFF	NULL
Non-NULL	1	1	ON/OFF	Loaded Successfully

### 1. The column in the table allows NULL values

- Both abc and 2000 become NULL after conversion to TinyInt due to type or precision issues. When strict mode is ON, such data will be filtered out. When OFF, NULL will be loaded.

### 2. Example with Decimal(1,0) type:

Original Data Type	Original Data Example	Value After Decimal Conversion	Strict Mode	Result
NULL		NULL	ON/OFF	NULL
Non-NULL	aaa	NULL	ON	Invalid (Filtered)
Non-NULL	aaa	NULL	OFF	NULL
Non-NULL	1 or 10	1 or 10	ON/OFF	Loaded Successfully

### 1. The column in the table allows NULL values

- abc becomes NULL after conversion to Decimal due to type issues. When strict mode is ON, such data will be filtered out. When OFF, NULL will be loaded.
- Although 10 exceeds the range, since its type meets decimal requirements, strict mode does not affect it.

## Restricting Partial Column Updates to Existing Columns Only

In strict mode, each row in a partial column update must have its Key already exist in the table. In non-strict mode, partial column updates can both update existing rows (where Key exists) and insert new rows (where Key doesn't exist).

For example, given a table structure as follows:

```
CREATE TABLE user_profile
(
 id INT,
 name VARCHAR(10),
 age INT,
 city VARCHAR(10),
 balance DECIMAL(9, 0),
 last_access_time DATETIME
) ENGINE=OLAP
UNIQUE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 1
PROPERTIES (
 "enable_unique_key_merge_on_write" = "true"
);
```

The table contains one record as follows:

```
mysql> select * from user_profile;
+-----+-----+-----+-----+-----+-----+
| id | name | age | city | balance | last_access_time |
+-----+-----+-----+-----+-----+-----+
| 1 | kevin | 18 | shenzhen | 400 | 2023-07-01 12:00:00 |
+-----+-----+-----+-----+-----+-----+
```

When using Insert Into with strict mode to perform partial column updates, the insertion will fail because the second and third rows with keys (3) and (18) do not exist in the original table:

```
SET enable_unique_key_partial_update=true;
SET enable_insert_strict = true;
INSERT INTO user_profile (id, balance, last_access_time) VALUES
(1, 500, '2023-07-03 12:00:01'),
(3, 23, '2023-07-03 12:00:02'),
(18, 9999999, '2023-07-03 12:00:03');
ERROR 1105 (HY000): errCode = 2, detailMessage = Insert has filtered data in strict mode
```

When using Insert Into with non-strict mode to perform partial column updates:

```
SET enable_unique_key_partial_update=true;
SET enable_insert_strict = false;
INSERT INTO user_profile (id, balance, last_access_time) VALUES
(1, 500, '2023-07-03 12:00:01'),
(3, 23, '2023-07-03 12:00:02'),
(18, 9999999, '2023-07-03 12:00:03');
```

The existing record will be updated, and two new records will be inserted. For columns not specified in the insert statement, if a default value is defined, it will be used; if the column allows NULL values, NULL will be used; otherwise, the insertion will fail.

The query result is as follows:

```
mysql> select * from user_profile;
+-----+-----+-----+-----+-----+-----+
| id | name | age | city | balance | last_access_time |
+-----+-----+-----+-----+-----+-----+
| 1 | kevin | 18 | shenzhen | 500 | 2023-07-03 12:00:01 |
| 3 | NULL | NULL | NULL | 23 | 2023-07-03 12:00:02 |
| 18 | NULL | NULL | NULL | 9999999 | 2023-07-03 12:00:03 |
+-----+-----+-----+-----+-----+-----+
```

## Enable Strict Mode

Strict mode (strict\_mode) defaults to False. Here's how to set it for different load methods:

### Stream Load

```
curl --location-trusted -u user:passwd \
-H "strict_mode: true" \
```

```
-T data.txt \
http://host:port/api/example_db/test_table/_stream_load
```

## Broker Load

```
LOAD LABEL example_db.label_1
(
 DATA INFILE("s3://bucket/data.txt")
 INTO TABLE test_table
)
WITH S3 (...)
PROPERTIES
(
 "strict_mode" = "true"
);
```

## Routine Load

```
CREATE ROUTINE LOAD example_db.job1 ON test_table
PROPERTIES
(
 "strict_mode" = "true"
)
FROM KAFKA (...);
```

## MySQL Load

```
LOAD DATA LOCAL INFILE 'data.txt'
INTO TABLE test_table
PROPERTIES
(
 "strict_mode" = "true"
);
```

## Insert Into

```
SET enable_insert_strict = true;
INSERT INTO test_table ...;
```

## Maximum Filter Ratio

Maximum Filter Ratio (max\_filter\_ratio) is a crucial load control parameter that defines the maximum allowable ratio of filtered data to total data during load. If the actual filter ratio is below the set maximum, the load task will continue and filtered data will be ignored; if it exceeds this ratio, the load task fails.

### Filter Ratio Calculation Method

- Filtered Rows: Data filtered out due to quality issues, including type errors, precision errors, string length exceeding limits, file column count mismatches, and rows filtered due to missing corresponding partitions.
- Unselected Rows: Data rows filtered out due to [Pre-filtering](#) or [Post-filtering](#) conditions.

- Loaded Rows: Data rows successfully loaded.

The filter ratio is calculated as:

$$\text{\#Filtered Rows} / (\text{\#Filtered Rows} + \text{\#Loaded Rows})$$

Note that Unselected Rows are not included in the filter ratio calculation.

## Configuring the Maximum Filter Ratio

The maximum filter ratio (max\_filter\_ratio) defaults to 0, meaning no filtered data is allowed. Here's how to set it for different load methods:

### Stream Load

```
curl --location-trusted -u user:passwd \
-H "max_filter_ratio: 0.1" \
-T data.txt \
http://host:port/api/example_db/test_table/_stream_load
```

### Broker Load

```
LOAD LABEL example_db.label_1
(
 DATA INFILE("s3://bucket/data.txt")
 INTO TABLE test_table
)
WITH S3 (...)
PROPERTIES
(
 "max_filter_ratio" = "0.1"
);
```

### Routine Load

```
CREATE ROUTINE LOAD example_db.job1 ON test_table
PROPERTIES
(
 "max_filter_ratio" = "0.1"
)
FROM KAFKA (...);
```

### MySQL Load

```
LOAD DATA LOCAL INFILE 'data.txt'
INTO TABLE test_table
PROPERTIES
(
 "max_filter_ratio" = "0.1"
);
```

**Insert Into sql** SET insert\_max\_filter\_ratio = 0.1; INSERT INTO test\_table FROM S3/HDFS/LOCAL();

**For Insert Into statements, insert\_max\_filter\_ratio only takes effect when enable\_insert\_strict = false, and only applies to INSERT INTO FROM S3/HDFS/LOCAL() syntax. The default value is 1.0, which means that all abnormal data are allowed to be filtered.**

# Transforming Data During Load

Doris provides powerful data transformation capabilities during data loading, which can simplify data processing workflows and reduce dependency on additional ETL tools. It mainly supports four types of transformations:

- **Column Mapping:** Map source data columns to different columns in the target table.
- **Column Transformation:** Transform source data in real-time using functions and expressions.
- **Pre-filtering:** Filter out unwanted raw data before column mapping and transformation.
- **Post-filtering:** Filter the final results after column mapping and transformation.

Through these built-in data transformation functions, you can improve loading efficiency and ensure consistency in data processing logic.

## Load Syntax

### Stream Load

Configure data transformation by setting the following parameters in HTTP headers:

Parameter	Description
columns	Specify column mapping and transformation
where	Specify post-filtering

**Note:** Stream Load does not support pre-filtering.

Example:

```
curl --location-trusted -u user:passwd \
 -H "columns: k1, k2, tmp_k3, k3 = tmp_k3 + 1" \
 -H "where: k1 > 1" \
 -T data.csv \
 http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

### Broker Load

Implement data transformation in SQL statements using the following clauses:

Clause	Description
column list	Specify column mapping, format: (k1, k2, tmp_k3)
SET	Specify column transformation

Clause	Description
PRECEDING FILTER	Specify pre-filtering
WHERE	Specify post-filtering

Example:

```
LOAD LABEL test_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE `test_tbl`
 (k1, k2, tmp_k3)
 PRECEDING FILTER k1 = 1
 SET (
 k3 = tmp_k3 + 1
)
 WHERE k1 > 1
)
WITH S3 (...);
```

## Routine Load

Implement data transformation in SQL statements using the following clauses:

Clause	Description
COLUMNS	Specify column mapping and transformation
PRECEDING FILTER	Specify pre-filtering
WHERE	Specify post-filtering

Example:

```
CREATE ROUTINE LOAD test_db.label1 ON test_tbl
 COLUMNS(k1, k2, tmp_k3, k3 = tmp_k3 + 1),
 PRECEDING FILTER k1 = 1,
 WHERE k1 > 1
 ...
```

## Insert Into

Insert Into can directly perform data transformation in the SELECT statement, using the WHERE clause for data filtering.

## Column Mapping

Column mapping is used to define the correspondence between source data columns and target table columns. It can handle the following scenarios: - The order of source data columns and target table columns is inconsistent - The number of source data columns and target table columns is inconsistent

## Implementation Principle

Column mapping implementation can be divided into two steps:

- **Step 1: Data Source Parsing** - Parse raw data into intermediate variables based on data format
- **Step 2: Column Mapping and Assignment** - Map intermediate variables to target table fields by column name

The following are processing flows for three different data formats:

### Load CSV Format Data

## Load JSON Format Data with Specified jsonpaths

## Load JSON Format Data without Specified jsonpaths

## Load JSON Data with Specified jsonpaths

Assume the following source data (column headers are for illustration only, no actual headers exist):

```
{"k1":1,"k2":"100","k3":"beijing","k4":1.1}
{"k1":2,"k2":"200","k3":"shanghai","k4":1.2}
{"k1":3,"k2":"300","k3":"guangzhou","k4":1.3}
{"k1":4,"k2":"\N","k3":"chongqing","k4":1.4}
```

## Create Target Table

```
CREATE TABLE example_table
(
 col1 INT,
 col2 STRING,
 col3 INT,
 col4 DOUBLE
) ENGINE = OLAP
DUPLICATE KEY(col1)
DISTRIBUTED BY HASH(col1) BUCKETS 1;
```

## Load Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "columns:col1, col3, col2, col4" \
-H "jsonpaths:[\"$.k1\", \"$.k2\", \"$.k3\", \"$.k4\"]" \
-H "format:json" \
-H "read_json_by_line:true" \
-T data.json \
-X PUT \
http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label_broker
(
 DATA INFILE("s3://bucket_name/data.json")
 INTO TABLE example_table
 FORMAT AS "json"
 (col1, col3, col2, col4)
 PROPERTIES
 (
 "jsonpaths" = "[\"$.k1\", \"$.k2\", \"$.k3\", \"$.k4\"]"
)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(col1, col3, col2, col4)
PROPERTIES
(
 "format" = "json",
 "jsonpaths" = "[\"$.k1\", \"$.k2\", \"$.k3\", \"$.k4\"]",
 "read_json_by_line" = "true"
)
FROM KAFKA (...);
```

## Query Results

```
mysql> SELECT * FROM example_table;
```

col1	col2	col3	col4
1	beijing	100	1.1
2	shanghai	200	1.2
3	guangzhou	300	1.3
4	chongqing	NULL	1.4

## Load JSON Data without Specified jsonpaths

Assume the following source data (column headers are for illustration only, no actual headers exist):

```
{"k1":1,"k2":"100","k3":"beijing","k4":1.1}
{"k1":2,"k2":"200","k3":"shanghai","k4":1.2}
{"k1":3,"k2":"300","k3":"guangzhou","k4":1.3}
{"k1":4,"k2":"\N","k3":"chongqing","k4":1.4}
```

## Create Target Table

```
CREATE TABLE example_table
(
 col1 INT,
 col2 STRING,
 col3 INT,
 col4 DOUBLE
) ENGINE = OLAP
DUPLICATE KEY(col1)
DISTRIBUTED BY HASH(col1) BUCKETS 1;
```

## Load Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "columns:k1, k3, k2, k4,col1 = k1, col2 = k3, col3 = k2, col4 = k4" \
-H "format:json" \
-H "read_json_by_line:true" \
-T data.json \
-X PUT \
http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label_broker
(
 DATA INFILE("s3://bucket_name/data.json")
 INTO TABLE example_table
```

```

FORMAT AS "json"
(k1, k3, k2, k4)
SET (
 col1 = k1,
 col2 = k3,
 col3 = k2,
 col4 = k4
)
)
WITH s3 (...);

```

- Routine Load

```

CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k3, k2, k4, col1 = k1, col2 = k3, col3 = k2, col4 = k4),
PROPERTIES
(
 "format" = "json",
 "read_json_by_line" = "true"
)
FROM KAFKA (...);

```

## Query Results

```

mysql> SELECT * FROM example_table;
+-----+-----+-----+-----+
| col1 | col2 | col3 | col4 |
+-----+-----+-----+-----+
| 1 | beijing | 100 | 1.1 |
| 2 | shanghai | 200 | 1.2 |
| 3 | guangzhou | 300 | 1.3 |
| 4 | chongqing | NULL | 1.4 |
+-----+-----+-----+-----+

```

## Adjusting Column Order

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```

column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4

```

The target table has four columns: k1, k2, k3, and k4. We want to map the columns as follows:

```

column1 -> k1
column2 -> k3
column3 -> k2
column4 -> k4

```

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 STRING,
 k3 INT,
 k4 DOUBLE
) ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1,k3,k2,k4" \
-T data.csv \
-X PUT \
http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label_broker
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k3, k2, k4)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k3, k2, k4),
COLUMNS TERMINATED BY ","
FROM KAFKA (...);
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 2 | shanghai | 200 | 1.2 |
| 4 | chongqing | NULL | 1.4 |
| 3 | guangzhou | 300 | 1.3 |
| 1 | beijing | 100 | 1.1 |
+-----+-----+-----+-----+
```

## Source File Columns Exceed Table Columns

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has three columns: k1, k2, and k3. We only need the first, second, and fourth columns from the source file, with the following mapping relationship:

```
column1 -> k1
column2 -> k2
column4 -> k3
```

To skip certain columns in the source file, you can use any column name that does not exist in the target table during column mapping. These column names can be customized and are not restricted. The data in these columns will be automatically ignored during loading.

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 STRING,
 k3 DOUBLE
) ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u usr:passwd \
-H "column_separator:," \
-H "columns: k1,k2,tmp_skip,k3" \
-T data.csv \
http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label_broker
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (tmp_k1, tmp_k2, tmp_skip, tmp_k3)
 SET (
```

```

 k1 = tmp_k1,
 k2 = tmp_k2,
 k3 = tmp_k3
)
)
WITH s3 (...);

```

- Routine Load

```

CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, tmp_skip, k3),
PROPERTIES
(
 "format" = "csv",
 "column_separator" = ",",
)
FROM KAFKA (...);

```

Note: The tmp\_skip in the example can be replaced with any name, as long as it is not in the column definition of the target table.

## Query Results

```

mysql> select * from example_table;
+-----+-----+-----+
| k1 | k2 | k3 |
+-----+-----+-----+
| 1 | 100 | 1.1 |
| 2 | 200 | 1.2 |
| 3 | 300 | 1.3 |
| 4 | NULL | 1.4 |
+-----+-----+-----+

```

## Source File Columns Less Than Table Columns

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```

column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4

```

The target table has five columns: k1, k2, k3, k4, and k5. We only need the first, second, third, and fourth columns from the source file, with the following mapping relationship:

```

column1 -> k1
column2 -> k3
column3 -> k2

```

```
column4 -> k4
k5 uses the default value
```

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 STRING,
 k3 INT,
 k4 DOUBLE,
 k5 INT DEFAULT 2
) ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1,k3,k2,k4" \
-T data.csv \
http://<fe_ip>:<fe_http_port>/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label_broker
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (tmp_k1, tmp_k3, tmp_k2, tmp_k4)
 SET (
 k1 = tmp_k1,
 k3 = tmp_k3,
 k2 = tmp_k2,
 k4 = tmp_k4
)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k3, k2, k4),
COLUMNS TERMINATED BY ","
FROM KAFKA (...);
```

Note: - If k5 has a default value, it will be filled with the default value - If k5 is a nullable column but has no default value, it will be filled with NULL - If k5 is a non-nullable column and has no default value, the load will fail

## Query Results

```
mysql> select * from example_table;
```

k1	k2	k3	k4	k5
1	beijing	100	1.1	2
2	shanghai	200	1.2	2
3	guangzhou	300	1.3	2
4	chongqing	NULL	1.4	2

## Column Transformation

Column transformation allows users to transform column values in the source file, supporting the use of most built-in functions. Column transformation is usually defined together with column mapping, i.e., first map the columns and then transform them.

### Transforming Source File Column Values Before Loading

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to transform the column values as follows:

```
column1 -> k1
column2 * 100 -> k3
column3 -> k2
column4 -> k4
```

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 STRING,
 k3 INT,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1, tmp_k3, k2, k4, k3 = tmp_k3 * 100" \
-T data.csv \
http://host:port/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, tmp_k3, k2, k4)
 SET (
 k3 = tmp_k3 * 100
)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, tmp_k3, k2, k4, k3 = tmp_k3 * 100),
COLUMNS TERMINATED BY ","
FROM KAFKA (...);
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 1 | beijing | 10000 | 1.1 |
| 2 | shanghai | 20000 | 1.2 |
| 3 | guangzhou | 30000 | 1.3 |
| 4 | chongqing | NULL | 1.4 |
+-----+-----+-----+-----+
```

## Using Case When Function for Conditional Column Transformation

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to transform the column values as follows:

```
column1 -> k1
column2 -> k2
column3 -> k3 (transformed to area id)
column4 -> k4
```

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT,
 k3 INT,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1, k2, tmp_k3, k4, k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END" \
-T data.csv \
http://host:port/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k2, tmp_k3, k4)
 SET (
 k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END
)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, tmp_k3, k4, k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END),
COLUMNS TERMINATED BY ","
FROM KAFKA (...);
```

## Query Results

```
mysql> select * from example_table;
```

k1	k2	k3	k4
1	100	1	1.1
2	200	2	1.2
3	300	3	1.3
4	NULL	4	1.4

## Handling NULL Values in Source Files

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to transform the column values as follows:

```
column1 -> k1 (transform NULL to 0)
column2 -> k2
column3 -> k3
column4 -> k4
```

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT,
 k3 INT,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1, tmp_k2, tmp_k3, k4, k2 = ifnull(tmp_k2, 0), k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END" \
```

```
-T data.csv \
http://host:port/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, tmp_k2, tmp_k3, k4)
 SET (
 k2 = ifnull(tmp_k2, 0),
 k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN
'chongqing' THEN 4 ELSE NULL END
)
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, tmp_k2, tmp_k3, k4, k2 = ifnull(tmp_k2, 0), k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN
'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END),
COLUMNS TERMINATED BY ","
FROM KAFKA (...);
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 1 | 100 | 1 | 1.1 |
| 2 | 200 | 2 | 1.2 |
| 3 | 300 | 3 | 1.3 |
| 4 | 0 | 4 | 1.4 |
+-----+-----+-----+-----+
```

## Pre-filtering

Pre-filtering is the process of filtering out unwanted raw data before column mapping and transformation. This feature is only supported in Broker Load and Routine Load.

Pre-filtering has the following application scenarios:

- Filtering before transformation

Scenarios where filtering is needed before column mapping and transformation, allowing for the removal of unwanted data before processing.

- Filtering columns that do not exist in the table, only as filtering indicators

For example, source data contains multiple tables' data (or multiple tables' data is written to the same Kafka message queue). Each row of data has a column indicating which table the data belongs to. Users can use pre-filtering conditions to filter out the corresponding table data for loading.

Pre-filtering has the following limitations: - Column filtering restrictions

Pre-filtering can only filter independent simple columns in the column list and cannot filter columns with expressions. For example: when the column mapping is (a, tmp, b = tmp + 1), column b cannot be used as a filter condition.

- Data processing restrictions

Pre-filtering occurs before data transformation, using raw data values for comparison, and raw data is treated as string type. For example: for data like \N, it will be compared directly as the \N string, rather than being converted to NULL before comparison.

### Example 1: Using Numeric Conditions for Pre-filtering

This example demonstrates how to filter source data using simple numeric comparison conditions. By setting the filter condition `k1 > 1`, we can filter out unwanted records before data transformation.

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

Pre-filtering condition:

```
column1 > 1, i.e., only load data where column1 > 1, and filter out other data.
```

### Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT,
 k3 STRING,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

### Loading Data

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k2, k3, k4)
 PRECEDING FILTER k1 > 1
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, k3, k4),
COLUMNS TERMINATED BY ",",
PRECEDING FILTER k1 > 1
FROM KAFKA (...)
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 2 | 200 | shanghai | 1.2 |
| 3 | 300 | guangzhou | 1.3 |
| 4 | NULL | chongqing | 1.4 |
+-----+-----+-----+-----+
```

## Example 2: Using Intermediate Columns to Filter Invalid Data

This example demonstrates how to handle data import scenarios containing invalid data.

Source data: plain text 1,1 2,abc 3,3

## Table Creation

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT NOT NULL
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

For column k2, which is of type INT, abc is invalid dirty data. To filter this data, we can introduce an intermediate column for filtering.

## Load Statements

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, tmp, k2 = tmp)
 PRECEDING FILTER tmp != "abc"
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, tmp, k2 = tmp),
COLUMNS TERMINATED BY ","
PRECEDING FILTER tmp != "abc"
FROM KAFKA (...);
```

## Load Results

```
mysql> select * from example_table;
+-----+-----+
| k1 | k2 |
+-----+-----+
| 1 | 1 |
| 3 | 3 |
+-----+-----+
```

## Post-filtering

Post-filtering is the process of filtering the final results after column mapping and transformation.

### Filtering Without Column Mapping and Transformation

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to load only the data where the fourth column is greater than 1.2.

### Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
```

```

 k2 INT,
 k3 STRING,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;

```

## Loading Data

- Stream Load

```

curl --location-trusted -u user:passwd \
-H "column_separator:," \
-H "columns: k1, k2, k3, k4" \
-H "where: k4 > 1.2" \
-T data.csv \
http://host:port/api/example_db/example_table/_stream_load

```

- Broker Load

```

LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k2, k3, k4)
 where k4 > 1.2
)
WITH s3 (...);

```

- Routine Load

```

CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, k3, k4),
COLUMNS TERMINATED BY ","
WHERE k4 > 1.2;
FROM KAFKA (...)

```

## Query Results

```

mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 3 | 300 | guangzhou | 1.3 |
| 4 | NULL | chongqing | 1.4 |
+-----+-----+-----+-----+

```

## Filtering Transformed Data

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to transform the column values as follows:

```
column1 -> k1
column2 -> k2
column3 -> k3 (transformed to area id)
column4 -> k4
```

We want to filter out the data where the transformed k3 value is 3.

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT,
 k3 INT,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
 -H "column_separator:," \
 -H "columns: k1, k2, tmp_k3, k4, k3 = case tmp_k3 when 'beijing' then 1 when 'shanghai' then 2 when 'guangzhou' then 3 when 'chongqing' then 4 else null end" \
 -H "where: k3 != 3" \
 -T data.csv \
 http://host:port/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k2, tmp_k3, k4)
 SET (
 k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing' THEN 4 ELSE NULL END
)
 WHERE k3 != 3
```

```
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, tmp_k3, k4),
COLUMNS TERMINATED BY ","
SET (
 k3 = CASE tmp_k3 WHEN 'beijing' THEN 1 WHEN 'shanghai' THEN 2 WHEN 'guangzhou' THEN 3 WHEN 'chongqing'
THEN 4 ELSE NULL END
)
WHERE k3 != 3;
FROM KAFKA (...)
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 1 | 100 | 1 | 1.1 |
| 2 | 200 | 2 | 1.2 |
| 4 | NULL | 4 | 1.4 |
+-----+-----+-----+-----+
```

## Multiple Conditions Filtering

Suppose we have the following source data (column names are for illustration purposes only, and there is no actual header):

```
column1,column2,column3,column4
1,100,beijing,1.1
2,200,shanghai,1.2
3,300,guangzhou,1.3
4,\N,chongqing,1.4
```

The target table has four columns: k1, k2, k3, and k4. We want to filter out the data where k1 is NULL and k4 is less than 1.2.

## Creating the Target Table

```
CREATE TABLE example_table
(
 k1 INT,
 k2 INT,
 k3 STRING,
 k4 DOUBLE
)
ENGINE = OLAP
DUPLICATE KEY(k1)
DISTRIBUTED BY HASH(k1) BUCKETS 1;
```

## Loading Data

- Stream Load

```
curl --location-trusted -u user:passwd \
 -H "column_separator:," \
 -H "columns: k1, k2, k3, k4" \
 -H "where: k1 is not null and k4 > 1.2" \
 -T data.csv \
 http://host:port/api/example_db/example_table/_stream_load
```

- Broker Load

```
LOAD LABEL example_db.label1
(
 DATA INFILE("s3://bucket_name/data.csv")
 INTO TABLE example_table
 COLUMNS TERMINATED BY ","
 (k1, k2, k3, k4)
 where k1 is not null and k4 > 1.2
)
WITH s3 (...);
```

- Routine Load

```
CREATE ROUTINE LOAD example_db.example_routine_load ON example_table
COLUMNS(k1, k2, k3, k4),
COLUMNS TERMINATED BY ","
WHERE k1 is not null and k4 > 1.2
FROM KAFKA (...);
```

## Query Results

```
mysql> select * from example_table;
+-----+-----+-----+-----+
| k1 | k2 | k3 | k4 |
+-----+-----+-----+-----+
| 3 | 300 | guangzhou | 1.3 |
| 4 | NULL | chongqing | 1.4 |
+-----+-----+-----+-----+
```

# Load High Availability

---

## Load High Availability

### Overview

Doris provides various mechanisms to ensure high availability during data import. This article will detail Doris's default import behavior and additional options for improving import availability, especially the minimum write replica number feature.

### Majority Write

By default, Doris adopts a majority write strategy to ensure data reliability and consistency:

- An import is considered successful when the number of successfully written replicas exceeds half of the total number of replicas.
- For example, for a table with three replicas, at least two replicas must be successfully written for the import to be considered successful.

### How It Works

1. Data Distribution: The import task first distributes data to all relevant BE nodes.
2. Parallel Writing: Each BE node processes data writing operations in parallel.
3. Write Confirmation: After completing the data write, each BE node sends a confirmation to the FE.
4. Majority Judgment: The FE counts the number of successfully written replicas, and considers the import successful when a majority is reached.
5. Transaction Commit: The FE commits the import transaction, making the data visible externally.
6. Asynchronous Replication: For replicas that were not successfully written, the system will asynchronously replicate data in the background to ensure eventual consistency across all replicas.

The majority write strategy is Doris's balance between data reliability and system availability. For scenarios with special requirements, Doris provides other options such as the minimum write replica number to further enhance system flexibility.

### Minimum Write Replica Number

While the majority write strategy ensures data reliability, it may affect system availability in certain scenarios. For example, in a two-replica situation, both replicas must be successfully written to complete the import, meaning no replica is allowed to be unavailable during the import process.

To address this issue and improve import availability, Doris provides the Min Load Replica Num option.

## Feature Description

The minimum write replica number allows users to specify the minimum number of replicas that need to be successfully written during data import. The import is considered successful when the number of successfully written replicas is greater than or equal to this value.

## Use Cases

- When some nodes are unavailable, but data import still needs to be guaranteed.
- When there are high requirements for data import speed, and users are willing to sacrifice some reliability for higher availability.

## Configuration Methods

### 1. Single Table Configuration

a. Set when creating a table:

```
CREATE TABLE example_table
(
 id INT,
 name STRING
)
DUPLICATE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 10
PROPERTIES
(
 'replication_num' = '3',
 'min_load_replica_num' = '2'
);
```

b. Modify an existing table:

```
ALTER TABLE example_table
SET ('min_load_replica_num' = '2');
```

### 2. Global Configuration

Set through the FE configuration item `min_load_replica_num`.

- Valid values: greater than 0
- Default value: -1 (indicating that the global minimum write replica number is not enabled)

Priority: Table property > Global configuration > Default majority rule

If the table property is not set or invalid, and the global configuration is valid, the minimum write replica number for the table is:  $\min(\text{FE configured min\_load\_replica\_num}, \text{table's replica number}/2 + 1)$

For viewing and modifying FE configuration items, please refer to the [FE Configuration Document](#).

## Other High Availability Mechanisms

In addition to the minimum write replica number option, Doris also adopts the following mechanisms to improve import availability:

1. Import Retry: Automatically retry failed import tasks caused by temporary failures.
2. Load Balancing: Distribute import tasks to different BE nodes to avoid excessive pressure on a single point.
3. Transaction Mechanism: Ensure data consistency, automatically rollback in case of failure.

# High Concurrency LOAD Optimization(Group Commit)

---

In high-frequency small batch write scenarios, traditional loading methods have the following issues:

- Each load creates an independent transaction, requiring FE to parse SQL and generate execution plans, affecting overall performance
- Each load generates a new version, causing rapid version growth and increasing background compaction pressure

To solve these problems, Doris introduced the Group Commit mechanism. Group Commit is not a new loading method, but rather an optimization extension of existing loading methods, mainly targeting:

- `INSERT INTO tbl VALUES(...)` statements
- Stream Load

By merging multiple small batch loads into one large transaction commit in the background, it significantly improves high-concurrency small batch write performance. Additionally, using Group Commit with `PreparedStatement` can achieve even higher performance improvements.

## Group Commit Modes

Group Commit has three modes:

- Off Mode (`off_mode`)

Group Commit is disabled.

- Synchronous Mode (`sync_mode`)

Doris commits multiple loads in one transaction based on load and table's `group_commit_interval` property, returning after transaction commit. This is suitable for high-concurrency write scenarios requiring immediate data visibility after loading.

- Asynchronous Mode (`async_mode`)

Doris first writes data to WAL (Write Ahead Log), then returns immediately. Doris asynchronously commits data based on load and table's `group_commit_interval` property, making data visible after commit. To prevent WAL from occupying too much disk space, it automatically switches to `sync_mode` for large single loads. This is suitable for write latency-sensitive and high-frequency write scenarios.

WAL count can be viewed through FE http interface as shown [here](#), or by searching for `wal` keyword in BE metrics.

## How to Use Group Commit

Assuming the table structure is:

```
CREATE TABLE `dt` (
 `id` int(11) NOT NULL,
 `name` varchar(50) NULL,
 `score` int(11) NULL
) ENGINE=OLAP
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
 "replication_num" = "1"
);
```

## Using JDBC

When users write using JDBC's `insert into values` method, to reduce SQL parsing and planning overhead, we support MySQL protocol's PreparedStatement feature on the FE side. When using PreparedStatement, SQL and its load plan are cached in session-level memory cache, and subsequent loads directly use the cached objects, reducing FE CPU pressure. Here's an example of using PreparedStatement in JDBC:

### 1. Set JDBC URL and enable Prepared Statement on Server side

```
url = jdbc:mysql://127.0.0.1:9030/db?
useServerPrepStmts=true&useLocalSessionState=true&rewriteBatchedStatements=true&cachePrepStmts=true&prepStmtC
acheSqlLimit=99999&prepStmtCacheSize=500
```

### 2. Configure group\_commit session variable in one of two ways:

- Through JDBC url by adding `sessionVariables=group_commit=async_mode`

```
url = jdbc:mysql://127.0.0.1:9030/db?
useServerPrepStmts=true&useLocalSessionState=true&rewriteBatchedStatements=true&cachePrepStmts=true&prepStmtC
acheSqlLimit=99999&prepStmtCacheSize=500&sessionVariables=group_commit=async_mode
```

- Through SQL execution

```
try (Statement statement = conn.createStatement()) {
 statement.execute("SET group_commit = async_mode;");
}
```

### 3. Use PreparedStatement

```
private static final String JDBC_DRIVER = "com.mysql.jdbc.Driver";
private static final String URL_PATTERN = "jdbc:mysql://%s:%d/%s?
useServerPrepStmts=true&useLocalSessionState=true&rewriteBatchedStatements=true&cachePrepStmts=true&prepStmtC
acheSqlLimit=99999&prepStmtCacheSize=50&sessionVariables=group_commit=async_mode";
private static final String HOST = "127.0.0.1";
private static final int PORT = 9030;
private static final String DB = "db";
private static final String TBL = "dt";
private static final String USER = "root";
private static final String PASSWD = "";
private static final int INSERT_BATCH_SIZE = 10;

private static void groupCommitInsertBatch() throws Exception {
 Class.forName(JDBC_DRIVER);
 // add rewriteBatchedStatements=true and cachePrepStmts=true in JDBC url
```

```

// set session variables by sessionVariables=group_commit=async_mode in JDBC url
try (Connection conn = DriverManager.getConnection(
 String.format(URL_PATTERN, HOST, PORT, DB), USER, PASSWD)) {

 String query = "insert into " + TBL + " values(?, ?, ?)";
 try (PreparedStatement stmt = conn.prepareStatement(query)) {
 for (int j = 0; j < 5; j++) {
 // 10 rows per insert
 for (int i = 0; i < INSERT_BATCH_SIZE; i++) {
 stmt.setInt(1, i);
 stmt.setString(2, "name" + i);
 stmt.setInt(3, i + 10);
 stmt.addBatch();
 }
 int[] result = stmt.executeBatch();
 }
 }
} catch (Exception e) {
 e.printStackTrace();
}
}

```

Note: Since high-frequency insert into statements will print large amounts of audit logs affecting final performance, printing prepared statement audit logs is disabled by default. You can control whether to print prepared statement audit logs through session variable settings.

```

Configure session variable to enable printing prepared statement audit log, default is false
set enable_prepared_stmt_audit_log=true;

```

For more about **JDBC** usage, refer to [Using Insert Method to Synchronize Data](#).

## Using Golang for Group Commit

Since Golang has limited support for prepared statements, we can improve Group Commit performance through manual client-side batching. Here's a sample program:

```

package main

import (
 "database/sql"
 "fmt"
 "math/rand"
 "strings"
 "sync"
 "sync/atomic"
 "time"

 _ "github.com/go-sql-driver/mysql"
)

const (
 host = "127.0.0.1"
 port = 9030
 db = "test"
 user = "root"
 password = ""

}
```

## INSERT INTO VALUES

- Asynchronous Mode

```
Configure session variable to enable group commit (default is off_mode), enable asynchronous mode
mysql> set group_commit = async_mode;

The returned label is prefixed with group_commit, indicating whether group commit is used
mysql> insert into dt values(1, 'Bob', 90), (2, 'Alice', 99);
Query OK, 2 rows affected (0.05 sec)
{'label': 'group_commit_a145ce07f1c972fc-bd2c54597052a9ad', 'status': 'PREPARE', 'txnId': '181508'}
```

# The label, txn\_id, and previous one are the same, indicating that they are accumulated into the same import task

```
mysql> insert into dt(id, name) values(3, 'John');
Query OK, 1 row affected (0.01 sec)
{'label': 'group_commit_a145ce07f1c972fc-bd2c54597052a9ad', 'status': 'PREPARE', 'txnId': '181508'}
```

# Cannot query immediately

```
mysql> select * from dt;
Empty set (0.01 sec)
```

# 10 seconds later, data can be queried, and data visibility delay can be controlled by table attribute group\_commit\_interval.

```
mysql> select * from dt;
+-----+-----+-----+
| id | name | score |
+-----+-----+-----+
| 1 | Bob | 90 |
| 2 | Alice| 99 |
| 3 | John | NULL |
+-----+-----+-----+
3 rows in set (0.02 sec)
```

- Synchronous Mode

```
Configure session variable to enable group commit (default is off_mode), enable synchronous mode
mysql> set group_commit = sync_mode;

The returned label is prefixed with group_commit, indicating whether group commit is used, and import time is at least table attribute group_commit_interval.
mysql> insert into dt values(4, 'Bob', 90), (5, 'Alice', 99);
Query OK, 2 rows affected (10.06 sec)
{'label': 'group_commit_d84ab96c09b60587_ec455a33cb0e9e87', 'status': 'PREPARE', 'txnId': '3007', 'query_id': 'fc6b94085d704a94-a69bfc9a202e66e2'}
```

# Data can be read immediately

```
mysql> select * from dt;
+-----+-----+-----+
| id | name | score |
+-----+-----+-----+
```

```
+-----+-----+-----+
| 1 | Bob | 90 |
| 2 | Alice | 99 |
| 3 | John | NULL |
| 4 | Bob | 90 |
| 5 | Alice | 99 |
+-----+-----+-----+
5 rows in set (0.03 sec)
```

- Off Mode

```
mysql> set group_commit = off_mode;
```

## Stream Load

Assuming data.csv contains:

```
6,Amy,60
7,Ross,98
```

- Asynchronous Mode

```
Import with "group_commit:async_mode" configuration in header

curl --location-trusted -u {user}:{passwd} -T data.csv -H "group_commit:async_mode" -H "column_separator:,"
http://{fe_host}:{http_port}/api/db/dt/_stream_load
{
 "TxnId": 7009,
 "Label": "group_commit_c84d2099208436ab_96e33fda01eddba8",
 "Comment": "",
 "GroupCommit": true,
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 2,
 "NumberLoadedRows": 2,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 19,
 "LoadTimeMs": 35,
 "StreamLoadPutTimeMs": 5,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 26
}

The returned GroupCommit is true, indicating that the group commit process is entered
The returned Label is prefixed with group_commit, indicating the label associated with the import that
truly consumes data
```

- Synchronous Mode

```
Import with "group_commit:sync_mode" configuration in header

curl --location-trusted -u {user}:{passwd} -T data.csv -H "group_commit:sync_mode" -H "column_separator:,"
http://{fe_host}:{http_port}/api/db/dt/_stream_load
{
 "TxnId": 3009,
 "Label": "group_commit_d941bf17f6efcc80_ccf4afdde9881293",
```

```

 "Comment": "",
 "GroupCommit": true,
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 2,
 "NumberLoadedRows": 2,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 19,
 "LoadTimeMs": 10044,
 "StreamLoadPutTimeMs": 4,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 10038
}

The returned GroupCommit is true, indicating that the group commit process is entered
The returned Label is prefixed with group_commit, indicating the label associated with the import that
truly consumes data

```

About Stream Load usage, please refer to [Stream Load](#).

Data is automatically committed when either time interval (default 10 seconds) or data volume (default 64 MB) condition is met. These parameters should be used together and tuned based on actual scenarios.

## Modifying Commit Interval

Default commit interval is 10 seconds, users can adjust through table configuration:

```

Modify commit interval to 2 seconds
ALTER TABLE dt SET ("group_commit_interval_ms" = "2000");

```

**Parameter Adjustment Recommendations:** - Shorter intervals (e.g., 2 seconds): - Pros: Lower data visibility latency, suitable for scenarios requiring high real-time performance - Cons: More commits, faster version growth, higher background compaction pressure

- Longer intervals (e.g., 30 seconds):
  - Pros: Larger commit batches, slower version growth, lower system overhead
  - Cons: Higher data visibility latency

Recommend setting based on business tolerance for data visibility delay. If system pressure is high, consider increasing the interval.

## Modifying Commit Data Volume

Group Commit's default commit data volume is 64 MB, users can adjust through table configuration:

```

Modify commit data volume to 128MB
ALTER TABLE dt SET ("group_commit_data_bytes" = "134217728");

```

**Parameter Adjustment Recommendations:** - Smaller threshold (e.g., 32MB): - Pros: Less memory usage, suitable for resource-constrained environments - Cons: Smaller commit batches, potentially limited throughput

- Larger threshold (e.g., 256MB):
  - Pros: Higher batch commit efficiency, greater system throughput

- Cons: Uses more memory

Recommend balancing based on system memory resources and data reliability requirements. If memory is sufficient and higher throughput is desired, consider increasing to 128MB or more.

## BE Configuration

### 1. group\_commit\_wal\_path

- Description: Directory for storing group commit WAL files
- Default: Creates a wal directory under each configured storage\_root\_path. Configuration example:

```
group_commit_wal_path=/data1/storage/wal;/data2/storage/wal;/data3/storage/wal
```

## Usage Limitations

### • Group Commit Limitations

- INSERT INTO VALUES statements degrade to non-Group Commit mode in these cases:
  - Transaction writes (Begin; INSERT INTO VALUES; COMMIT)
  - Specified Label (INSERT INTO dt WITH LABEL {label} VALUES)
  - VALUES containing expressions (INSERT INTO dt VALUES (1 + 100))
  - Column update writes
  - Table doesn't support lightweight mode changes
- Stream Load degrades to non-Group Commit mode in these cases:
  - Using two-phase commit
  - Specified Label (-H "label:my\_label")
  - Column update writes
  - Table doesn't support lightweight mode changes

### • Unique Model

- Group Commit doesn't guarantee commit order, recommend using Sequence column to ensure data consistency.

### • WAL Limitations

- async\_mode writes data to WAL, deletes after success, recovers through WAL on failure.
- WAL files are stored with a single replica on one BE, disk damage or accidental file deletion may cause data loss.
- When offlining BE nodes, use DECOMMISSION command to prevent data loss.
- async\_mode switches to sync\_mode in these cases:
  - Load data volume too large (exceeds 80% of WAL single directory space)
  - Unknown data volume chunked stream load
  - Insufficient disk space
- During heavyweight Schema Change, Group Commit writes are rejected, client needs to retry.

## Performance

We have separately tested the write performance of group commit in high-concurrency scenarios with small data volumes using Stream Load and JDBC (in async mode).

### Stream Load

### Environment

- 1 Front End (FE) server: Alibaba Cloud with 8-core CPU, 16GB RAM, and one 100GB ESSD PL1 SSD.
- 3 Backend (BE) servers: Alibaba Cloud with 16-core CPU, 64GB RAM, and one 1TB ESSD PL1 SSD.
- 1 Test Client: Alibaba Cloud with 16-core CPU, 64GB RAM, and one 100GB ESSD PL1 SSD.
- The version for testing is Doris-2.1.5.

### DataSet

- httplogs, 31 GB, 247249096 (247 million) rows

### Test Tool

- [doris-streamloader](#)

### Test Method

- Testing with different data sizes per request and concurrency levels between non group\_commit and group\_commit=async mode modes.

### Test Results

Load Way	Single-concurrency Data Size	Concurr ency	Cost Seconds	Rows / Seconds	MB / Seconds
group_commit	10 KB	10	3306	74,787	9.8
group_commit	10 KB	30	3264	75,750	10.0
group_commit	100 KB	10	424	582,447	76.7
group_commit	100 KB	30	366	675,543	89.0
group_commit	500 KB	10	187	1,318,661	173.7
group_commit	500 KB	30	183	1,351,087	178.0
group_commit	1 MB	10	178	1,385,148	182.5
group_commit	1 MB	30	178	1,385,148	182.5
group_commit	10 MB	10	177	1,396,887	184.0

Load Way	Single-concurrency Data Size	Concurr ency	Cost Seconds	Rows / Seconds	MB / Seconds
non group_commit	1 MB	10	2824	87,536	11.5
non group_commit	10 MB	10	450	549,442	68.9
non group_commit	10 MB	30	177	1,396,887	184.0

In the above test, the CPU usage of BE fluctuates between 10-40%.

The group\_commit effectively enhances load performance while reducing the number of versions, thereby alleviating the pressure on compaction.

## JDBC

### Environment

1 Front End (FE) server: Alibaba Cloud with an 8-core CPU, 16GB RAM, and one 100GB ESSD PL1 SSD.

1 Backend (BE) server: Alibaba Cloud with a 16-core CPU, 64GB RAM, and one 500GB ESSD PL1 SSD.

1 Test Client: Alibaba Cloud with a 16-core CPU, 64GB RAM, and one 100GB ESSD PL1 SSD.

The testing version is Doris-2.1.5.

Disable the printing of prepared statement audit logs to enhance performance.

### DataSet

- The data of tpch sf10 lineitem table, 20 files, 14 GB, 120 million rows

### Test Method

- [DataX](#)

### Test Method

- Use txtfilereader write data to mysqlwriter, config different concurrenncy and rows for per INSERT sql.

### Test Results

Rows per insert	Concurrency	Rows / Second	MB / Second
100	10	107,172	11.47
100	20	140,317	14.79
100	30	142,882	15.28

In the above test, the CPU usage of BE fluctuates between 10-20%, FE fluctuates between 60-70%.

## Insert into Sync Mode Small Batch Data

### Machine Configuration

- 1 Front-End (FE): Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 500GB ESSD PL1 cloud disk
- 5 Back-End (BE) nodes: Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 1TB ESSD PL1 cloud disk.
- 1 Testing Client: Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 100GB ESSD PL1 cloud disk
- Test version: Doris-2.1.5

### Dataset

- The data of tpch sf10 lineitem table.
- The create table statement is

```
CREATE TABLE IF NOT EXISTS lineitem (
 L_ORDERKEY INTEGER NOT NULL,
 L_PARTKEY INTEGER NOT NULL,
 L_SUPPKEY INTEGER NOT NULL,
 L_LINENUMBER INTEGER NOT NULL,
 L_QUANTITY DECIMAL(15,2) NOT NULL,
 L_EXTENDEDPRICE DECIMAL(15,2) NOT NULL,
 L_DISCOUNT DECIMAL(15,2) NOT NULL,
 L_TAX DECIMAL(15,2) NOT NULL,
 L_RETURNFLAG CHAR(1) NOT NULL,
 L_LINESTATUS CHAR(1) NOT NULL,
 L_SHIPDATE DATE NOT NULL,
 L_COMMITDATE DATE NOT NULL,
 L_RECEIPTDATE DATE NOT NULL,
 L_SHIPINSTRUCT CHAR(25) NOT NULL,
 L_SHIPMODE CHAR(10) NOT NULL,
 L_COMMENT VARCHAR(44) NOT NULL
)
DUPLICATE KEY(L_ORDERKEY, L_PARTKEY, L_SUPPKEY, L_LINENUMBER)
DISTRIBUTED BY HASH(L_ORDERKEY) BUCKETS 32
PROPERTIES (
 "replication_num" = "3"
);
```

### Testing Tool

- [Jmeter](#)

JMeter Parameter Settings as Shown in the Images

mts=true&prepStmtCacheSqlLimit=99999&prepStmtCacheSize=50&sessionVariables=group\_commit=a  
sync\_mode,enable\_nereids\_planner=false.

3. Set the Import Type to Prepared Update Statement.

4. Set the Import Statement.

5. Set the Values to Be Imported: Ensure that the imported values match the data types one by one.

## Testing Methodology

- Use JMeter to write data into Doris. Each thread writes 1 row of data per execution using the insert into statement.

## Test Results

- Data unit: rows per second.
- The following tests are divided into 30, 100, and 500 concurrency.

### Performance Test with 30 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group Commit Interval	10ms	20ms	50ms	100ms
	321.5	307.3	285.8	224.3

### Performance Test with 100 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group Commit Interval	10ms	20ms	50ms	100ms
	1175.2	1108.7	1016.3	704.5

### Performance Test with 500 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group Commit Interval	10ms	20ms	50ms	100ms
	3289.8	3686.7	3280.7	2609.2

## Insert into Sync Mode Large Batch Data

### Machine Configuration

- 1 Front-End (FE): Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 500GB ESSD PL1 cloud disk
- 5 Back-End (BE) nodes: Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 1TB ESSD PL1 cloud disk.
- 1 Testing Client: Alibaba Cloud, 16-core CPU, 64GB RAM, 1 x 100GB ESSD PL1 cloud disk
- Test version: Doris-2.1.5

### Dataset

- Insert into statement for 1000 rows: insert into tbl values(1,1)... (1000 rows omitted)

### Testing Tool

- [Jmeter](#)

## Testing Methodology

- Use JMeter to write data into Doris. Each thread writes 1000 row of data per execution using the insert into statement.

## Test Results

- Data unit: rows per second.
- The following tests are divided into 30, 100, and 500 concurrency.

### Performance Test with 30 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group commit interval	10ms	20ms	50ms	100ms
	92.2K	85.9K	84K	83.2K

### Performance Test with 100 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group commit interval	10ms	20ms	50ms	100ms
	70.4K	70.5K	73.2K	69.4K

### Performance Test with 500 Concurrent Users in Sync Mode, 5 BEs, and 3 Replicas

Group commit interval	10ms	20ms	50ms	100ms
	46.3K	47.7K	47.4K	46.5K

# Load Best Practices

---

## Table Model Selection

It is recommended to prioritize using the Duplicate Key model, which offers advantages in both data loading and query performance compared to other models. For more information, please refer to: [Data Model](#)

## Partition and Bucket Configuration

It is recommended to keep the size of a tablet between 1-10GB. Tablets that are too small may lead to poor aggregation performance and increase metadata management overhead; tablets that are too large may hinder replica migration and repair. For details, please refer to: [Data Distribution](#).

## Random Bucketing

When using Random bucketing, you can enable single-tablet loading mode by setting `load_to_single_tablet` to true. This mode can improve data loading concurrency and throughput while reducing write amplification during large-scale data loading. For details, refer to: [Random Bucketing](#)

## Batch Loading

Client-side batching: It is recommended to batch data (from several MB to GB in size) on the client side before loading. High-frequency small loads will cause frequent compaction, leading to severe write amplification issues. Server-side batching: For high-concurrency small data volume loading, it is recommended to enable [Group Commit](#) to implement batching on the server side.

## Partition Loading

It is recommended to load data from only a few partitions at a time. Loading from too many partitions simultaneously will increase memory usage and may cause performance issues. Each tablet in Doris has an active Memtable in memory, which is flushed to disk when it reaches a certain size. To prevent process OOM, when the active Memtable's memory usage is too high, it will trigger early flushing, resulting in many small files and affecting loading performance.

## Large-scale Data Batch Loading

When dealing with a large number of files or large data volumes, it is recommended to load in batches to avoid high retry costs in case of loading failures and to reduce system resource impact. For Broker Load, it is recommended not to exceed 100GB per batch. For large local data files, you can use Doris's streamloader tool, which automatically performs batch loading.

## Broker Load Concurrency

Compressed files/Parquet/ORC files: It is recommended to split files into multiple smaller files for loading to achieve higher concurrency.

Uncompressed CSV and JSON files: Doris will automatically split files and load them concurrently.

For concurrency strategies, please refer to: [Broker Load Configuration Parameters](#)

## **Stream Load Concurrency**

It is recommended to keep Stream load concurrency per BE under 128 (controlled by BE's `webserver_num_workers` parameter). High concurrency may cause webserver thread exhaustion and affect loading performance. Particularly when a single BE's concurrency exceeds 512 (`doris_max_remote_scanner_thread_pool_thread_num` parameter), it may cause the BE process to hang.

# Data Update Overview

In today’s data-driven decision-making landscape, data “freshness” has become a core competitive advantage for enterprises to stand out in fierce market competition. Traditional T+1 data processing models, due to their inherent latency, can no longer meet the stringent real-time requirements of modern business. Whether it’s achieving millisecond-level synchronization between business databases and data warehouses, dynamically adjusting operational strategies, or correcting erroneous data within seconds to ensure decision accuracy, robust real-time data update capabilities are crucial.

Apache Doris, as a modern real-time analytical database, has one of its core design goals to provide ultimate data freshness. Through its powerful data models and flexible update mechanisms, it successfully compresses data analysis latency from day-level and hour-level to second-level, providing a solid foundation for users to build real-time, agile business decision-making loops.

This document serves as an official guide that systematically explains Apache Doris’s data update capabilities, covering its core principles, diverse update and deletion methods, typical application scenarios, and performance best practices under different deployment modes, aiming to help you comprehensively master and efficiently utilize Doris’s data update functionality.

## 1. Core Concepts: Table Models and Update Mechanisms

In Doris, the **Data Model** of a data table determines its data organization and update behavior. To support different business scenarios, Doris provides three table models: Unique Key Model, Aggregate Key Model, and Duplicate Key Model. Among these, **the Unique Key Model is the core for implementing complex, high-frequency data updates**.

### 1.1. Table Model Overview

Table Model	Key Features	Update Capability	Use Cases
Unique Key Model	Built for real-time updates. Each data row is identified by a unique Primary Key, supporting row-level UPSERT (Update/Insert) and partial column updates.	Strongest, supports all update and deletion methods.	Order status updates, real-time user tag computation, CDC data synchronization, and other scenarios requiring frequent, real-time changes.
Aggregate Key Model	Pre-aggregates data based on specified Key columns. For rows with the same Key, Value columns are merged according to defined aggregation functions (such as SUM, MAX, MIN, REPLACE).	Limited, supports REPLACE-style updates and deletions based on Key columns.	Scenarios requiring real-time summary statistics, such as real-time reports, advertisement click statistics, etc.
Duplicate Key Model	Data only supports append-only writes, without any deduplication or aggregation operations. Even identical data rows are retained.	Limited, only supports conditional deletion through DELETE statements.	Log collection, user behavior tracking, and other scenarios that only need appending without updates.

## 1.2. Data Update Methods

Doris provides two major categories of data update methods: **updating through data load** and **updating through DML statements**.

### 1.2.1. Updating Through Load (UPSERT)

This is Doris's **recommended high-performance, high-concurrency** update method, primarily targeting the **Unique Key Model**. All load methods (Stream Load, Broker Load, Routine Load, INSERT INTO) naturally support UPSERT semantics. When new data is loaded, if its primary key already exists, Doris will overwrite the old row data with the new row data; if the primary key doesn't exist, it will insert a new row.

img

### 1.2.2. Updating Through UPDATE DML Statements

Doris supports standard SQL UPDATE statements, allowing users to update data based on conditions specified in the WHERE clause. This method is very flexible and supports complex update logic, such as cross-table join updates.

img

```
-- Simple update
UPDATE user_profiles SET age = age + 1 WHERE user_id = 1;

-- Cross-table join update
UPDATE sales_records t1
SET t1.user_name = t2.name
FROM user_profiles t2
WHERE t1.user_id = t2.user_id;
```

**Note:** The execution process of UPDATE statements involves first scanning data that meets the conditions, then rewriting the updated data back to the table. It's suitable for low-frequency, batch update tasks. **High-concurrency operations on UPDATE statements are not recommended** because concurrent UPDATE operations involving the same primary keys cannot guarantee data isolation.

### 1.2.3. Updating Through INSERT INTO SELECT DML Statements

Since Doris provides UPSERT semantics by default, using INSERT INTO SELECT can also achieve similar update effects as UPDATE.

## 1.3. Data Deletion Methods

Similar to updates, Doris also supports deleting data through both load and DML statements.

### 1.3.1. Mark Deletion Through Load

This is an efficient batch deletion method, primarily used for the **Unique Key Model**. Users can add a special hidden column DORIS\_DELETE\_SIGN when loading data. When the value of this column for a row is 1 or true, Doris will mark the corresponding data row with that primary key as deleted (the principle of delete sign will be explained in detail later).

```
// Stream Load load data, delete row with user_id = 2
// curl --location-trusted -u user:passwd -H "columns:user_id, __DORIS_DELETE_SIGN__" -T delete.json
http://fe_host:8030/api/db_name/table_name/_stream_load

// delete.json content
[
 {"user_id": 2, "__DORIS_DELETE_SIGN__": "1"}
]
```

### 1.3.2. Deletion Through DELETE DML Statements

Doris supports standard SQL DELETE statements that can delete data based on WHERE conditions.

- **Unique Key Model:** DELETE statements will rewrite the primary keys of rows meeting the conditions with deletion marks. Therefore, its performance is proportional to the amount of data to be deleted. The execution principle of DELETE statements on Unique Key Models is very similar to UPDATE statements, first reading the data to be deleted through queries, then writing it once more with deletion marks. Compared to UPDATE statements, DELETE statements only need to write Key columns and deletion mark columns, making them relatively lighter.
- **Duplicate/Aggregate Models:** DELETE statements are implemented by recording a delete predicate. During queries, this predicate serves as a runtime filter to filter out deleted data. Therefore, DELETE operations themselves are very fast, almost independent of the amount of deleted data. However, note that **high-frequency DELETE operations on Duplicate/Aggregate Models will accumulate many runtime filters, severely affecting subsequent query performance.**

```
DELETE FROM user_profiles WHERE last_login < '2022-01-01';
```

The following table provides a brief summary of using DML statements for deletion:

	Unique Key Model	Aggregate Model	Duplicate Model
Implementation	Delete Sign	Delete Predicate	Delete Predicate
Limitations	None	Delete conditions only for Key columns	None
Deletion Performance	Moderate	Fast	Fast

## 2. Deep Dive into Unique Key Model: Principles and Implementation

The Unique Key Model is the cornerstone of Doris's high-performance real-time updates. Understanding its internal working principles is crucial for fully leveraging its performance.

### 2.1. Merge-on-Write (MoW) vs. Merge-on-Read (MoR)

The Unique Key Model has two data merging strategies: Merge-on-Write (MoW) and Merge-on-Read (MoR). **Since Doris 2.1, MoW has become the default and recommended implementation.**

Feature	Merge-on-Write (MoW)	Merge-on-Read (MoR) - (Legacy)
<b>Core Concept</b>	Completes data deduplication and merging during data writing, ensuring only one latest record per primary key in storage.	Retains multiple versions during data writing, performs real-time merging during queries to return the latest version.
<b>Query Performance</b>	Extremely high. No additional merge operations needed during queries, performance approaches that of non-updated detail tables.	Poor. Requires data merging during queries, taking about 3-10 times longer than MoW and consuming more CPU and memory.
<b>Write Performance</b>	Has merge overhead during writing, with some performance loss compared to MoR (about 10-20% for small batches, 30-50% for large batches).	Fast writing speed, approaching detail tables.

Feature	Merge-on-Write (MoW)	Merge-on-Read (MoR) - (Legacy)
<b>Resource Consumption</b>	Consumes more CPU and memory during writing and background Compaction.	Consumes more CPU and memory during queries.
<b>Use Cases</b>	Most real-time update scenarios. Especially suitable for read-heavy, write-light businesses, providing ultimate query analysis performance.	Suitable for write-heavy, read-light scenarios, but no longer mainstream recommended.

The MoW mechanism trades a small cost during the writing phase for tremendous improvement in query performance, perfectly aligning with the OLAP system's "read-heavy, write-light" characteristics.

## 2.2. Conditional Updates (Sequence Column)

In distributed systems, out-of-order data arrival is a common problem. For example, an order status changes sequentially to "Paid" and "Shipped", but due to network delays, data representing "Shipped" might arrive at Doris before data representing "Paid".

To solve this problem, Doris introduces the **Sequence Column** mechanism. Users can specify a column (usually a timestamp or version number) as the Sequence column when creating tables. When processing data with the same primary key, Doris will compare their Sequence column values and **always retain the row with the largest Sequence value**, thus ensuring eventual consistency even when data arrives out of order.

```
CREATE TABLE order_status (
 order_id BIGINT,
 status_name STRING,
 update_time DATETIME
)
UNIQUE KEY(order_id)
DISTRIBUTED BY HASH(order_id)
PROPERTIES (
 "function_column.sequence_col" = "update_time" -- Specify update_time as Sequence column
);

-- 1. Write "Shipped" record (larger update_time)
-- {"order_id": 1001, "status_name": "Shipped", "update_time": "2023-10-26 12:00:00"}

-- 2. Write "Paid" record (smaller update_time, arrives later)
-- {"order_id": 1001, "status_name": "Paid", "update_time": "2023-10-26 11:00:00"}

-- Final query result, retains record with largest update_time
-- order_id: 1001, status_name: "Shipped", update_time: "2023-10-26 12:00:00"
```

## 2.3. Deletion Mechanism (DORIS\_DELETE\_SIGN) Workflow

The working principle of DORIS\_DELETE\_SIGN can be summarized as "logical marking, background cleanup".

- Execute Deletion:** When users delete data through load or DELETE statements, Doris doesn't immediately remove data from physical files. Instead, it writes a new record for the primary key to be deleted, with the DORIS\_DELETE\_SIGN column marked as 1.
- Query Filtering:** When users query data, Doris automatically adds a filter condition WHERE DORIS\_DELETE\_SIGN = 0 to the query plan, thus hiding all data marked for deletion from query results.
- Background Compaction:** Doris's background Compaction process periodically scans data. When it finds a primary key with both normal records and deletion mark records, it will physically remove both

records during the merge process, eventually freeing storage space.

This mechanism ensures quick response to deletion operations while asynchronously completing physical cleanup through background tasks, avoiding performance impact on online business.

The following diagram shows how DORIS\_DELETE\_SIGN works:

img

## 2.4 Partial Column Update

Starting from version 2.0, Doris supports powerful partial column update capabilities on Unique Key Models (MoW). When loading data, users only need to provide the primary key and columns to be updated; unprovided columns will maintain their original values unchanged. This greatly simplifies ETL processes for scenarios like wide table joining and real-time tag updates.

To enable this feature, you need to enable Merge-on-Write (MoW) mode when creating the Unique Key Model table. For INSERT INTO, set the session variable `enable_unique_key_partial_update` to `true` to enable partial column updates; for Stream Load and other import methods, configure the `partial_columns` parameter to enable partial column updates.

```
CREATE TABLE user_profiles (
 user_id BIGINT,
 name STRING,
 age INT,
 last_login DATETIME
)
UNIQUE KEY(user_id)
DISTRIBUTED BY HASH(user_id)
PROPERTIES (
 "enable_unique_key_merge_on_write" = "true"
);

-- Initial data
-- user_id: 1, name: 'Alice', age: 30, last_login: '2023-10-01 10:00:00'
```

```
-- load partial update data through Stream Load, only updating age and last_login
-- {"user_id": 1, "age": 31, "last_login": "2023-10-26 18:00:00"}

-- Updated data
-- user_id: 1, name: 'Alice', age: 31, last_login: '2023-10-26 18:00:00'
```

## Partial Column Update Principle Overview

Unlike traditional OLTP databases, Doris's partial column update is not in-place data update. To achieve better write throughput and query performance in Doris, partial column updates in Unique Key Models adopt an **“load-time missing field completion followed by full-row writing”** implementation approach.

Therefore, using Doris's partial column update has **“read amplification”** and **“write amplification”** effects. For example, updating 10 fields in a 100-column wide table requires Doris to complete the missing 90 fields during the write process. Assuming each field has similar size, a 1MB 10-field update will generate approximately 9MB of data reading (completing missing fields) and 10MB of data writing (writing the complete row to new files) in the Doris system, resulting in about 9x read amplification and 10x write amplification.

## Partial Column Update Performance Recommendations

Due to read and write amplification in partial column updates, and since Doris is a columnar storage system, the data reading process may generate significant random I/O, requiring high random read IOPS from storage. Since traditional mechanical disks have significant bottlenecks in random I/O, **if you want to use partial column update functionality for high-frequency writes, SSD drives are recommended, preferably NVMe interface**, which can provide the best random I/O support.

Additionally, **if the table is very wide, enabling row storage is also recommended to reduce random I/O**. After enabling row storage, Doris will store an additional copy of row-based data alongside columnar storage. Since row-based data stores each row continuously, it can read entire rows with a single I/O operation (columnar storage requires N I/O operations to read all missing fields, such as the previous example of a 100-column wide table updating 10 columns, requiring 90 I/O operations per row to read all fields).

## 3. Typical Application Scenarios

Doris's powerful data update capabilities enable it to handle various demanding real-time analysis scenarios.

### 3.1. CDC Real-time Data Synchronization

Capturing change data (Binlog) from upstream business databases (such as MySQL, PostgreSQL, Oracle) through tools like Flink CDC and writing it in real-time to Doris Unique Key Model tables is the most classic scenario for building real-time data warehouses.

- **Whole Database Synchronization:** Flink Doris Connector internally integrates Flink CDC, enabling automated, end-to-end whole database synchronization from upstream databases to Doris without manual table creation and field mapping configuration.
- **Ensuring Consistency:** Utilizes the Unique Key Model's UPSERT capability to handle upstream INSERT and UPDATE operations, uses DORIS\_DELETE\_SIGN to handle DELETE operations, and combines with Sequence columns (such as timestamps in Binlog) to handle out-of-order data, perfectly replicating upstream database states and achieving millisecond-level data synchronization latency.

img

### 3.2. Real-time Wide Table Joining

In many analytical scenarios, data from different business systems needs to be joined into user-wide tables or product-wide tables. Traditional approaches use offline ETL tasks (such as Spark or Hive) for periodic (T+1) joining, which has poor real-time performance and high maintenance costs. Alternatively, using Flink for real-time wide table join calculations and writing joined data to databases typically requires significant computational resources.

Using Doris's **partial column update** capability can greatly simplify this process:

1. Create a Unique Key Model wide table in Doris.
2. Write data streams from different sources (such as user basic information, user behavior data, transaction data, etc.) to this wide table in real-time through Stream Load or Routine Load.
3. Each data stream only updates its relevant fields. For example, user behavior data streams only update `page_view_count`, `last_login_time`, and other fields; transaction data streams only update `total_orders`, `total_amount`, and other fields.

This approach not only transforms wide table construction from offline ETL to real-time stream processing, greatly improving data freshness, but also reduces I/O overhead by only writing changed columns, improving write performance.

## 4. Best Practices

Following these best practices can help you use Doris's data update functionality more stably and efficiently.

1. **Prioritize load Updates:** For high-frequency, large-volume update operations, prioritize load methods like Stream Load and Routine Load over UPDATE DML statements.
2. **Batch Writes:** Avoid using INSERT INTO statements for individual high-frequency writes (such as > 100 TPS), as each INSERT incurs transaction overhead. If necessary, consider enabling Group Commit functionality to merge multiple small batch commits into one large transaction.
3. **Use High-frequency DELETE Carefully:** On Duplicate and Aggregate models, avoid high-frequency DELETE operations to prevent query performance degradation.
4. **Use TRUNCATE PARTITION for Partition Data Deletion:** If you need to delete entire partition data, use TRUNCATE PARTITION, which is much more efficient than DELETE.
5. **Execute UPDATE Serially:** Avoid concurrent execution of UPDATE tasks that might affect the same data rows.

## Conclusion

Apache Doris, with its powerful, flexible, and efficient data update capabilities centered on the Unique Key Model, truly breaks through the bottleneck of traditional OLAP systems in terms of data freshness. Whether through high-performance loads implementing UPSERT and partial column updates, or using Sequence columns to ensure consistency of out-of-order data, Doris provides complete solutions for building end-to-end real-time analytical applications.

By deeply understanding its core principles, mastering the applicable scenarios for different update methods, and following the best practices provided in this document, you will be able to fully unleash Doris's potential, making real-time data truly become a powerful engine driving business growth.

# Updating Data with UPDATE Command

---

This document explains how to use the UPDATE command to modify data in Doris. The UPDATE command is only applicable to tables with a Unique data model.

## Applicable Scenarios

- Small-scale data updates: Ideal for scenarios where a small amount of data needs to be corrected, such as fixing erroneous fields in certain records or updating the status of specific fields (e.g., order status updates).
- ETL batch processing of certain fields: Suitable for large-scale updates of a specific field, commonly seen in ETL processing scenarios. Note: Large-scale data updates should be infrequent.

## How It Works

The query engine uses its own filtering logic to identify the rows that need to be updated. Then, using the Unique model's Value column logic to replace old data with new data. The rows to be updated are modified and reinserted into the table to achieve row-level updates.

## Synchronization

The UPDATE syntax in Doris is synchronous, meaning that once the UPDATE statement is successfully executed, the update operation is completed and the data is immediately visible.

## Performance

The performance of the UPDATE statement is closely related to the number of rows to be updated and the efficiency of the query conditions.

- Number of rows to be updated: The more rows that need to be updated, the slower the UPDATE statement will be. For small-scale updates, Doris supports a frequency similar to INSERT INTO statements. For large-scale updates, due to the long execution time, it is only suitable for infrequent calls.
- Efficiency of query conditions: The UPDATE implementation first reads the rows that meet the query conditions. Therefore, if the query conditions are efficient, the UPDATE speed will be fast. Ideally, the condition columns should hit the index or partition bucket pruning, so Doris does not need to scan the entire table and can quickly locate the rows that need to be updated, thereby improving update efficiency. It is strongly recommended not to include value columns in the condition columns.

## Usage Example

Assume there is a transaction details table with the following structure in a financial risk control scenario:

```

CREATE TABLE transaction_details (
 transaction_id BIGINT NOT NULL, -- Unique transaction ID
 user_id BIGINT NOT NULL, -- User ID
 transaction_date DATE NOT NULL, -- Transaction date
 transaction_time DATETIME NOT NULL, -- Transaction time
 transaction_amount DECIMAL(18, 2), -- Transaction amount
 transaction_device STRING, -- Transaction device
 transaction_region STRING, -- Transaction region
 average_daily_amount DECIMAL(18, 2), -- Average daily transaction amount over the last 3 months
 recent_transaction_count INT, -- Number of transactions in the last 7 days
 has_dispute_history BOOLEAN, -- Whether there is a dispute history
 risk_level STRING -- Risk level
)
UNIQUE KEY(transaction_id)
DISTRIBUTED BY HASH(transaction_id) BUCKETS 16
PROPERTIES (
 "replication_num" = "3", -- Number of replicas, default is 3
 "enable_unique_key_merge_on_write" = "true" -- Enable MOW mode, support merge updates
);

```

The following transaction data exists:

transaction_id	user_id	transaction_date	transaction_time	transaction_amount	transaction_device	transaction_region	average_daily_amount	recent_transaction_count	has_dispute_history	risk_level
1001	5001	2024-11-24	2024-11-24 14:30:00	100.00	iPhone 12	New York	100.00	10	0	NULL
1002	5002	2024-11-24	2024-11-24 03:30:00	120.00	iPhone 12	New York	100.00	15	0	NULL
1003	5003	2024-11-24	2024-11-24 10:00:00	150.00	Samsung S21	Los Angeles	100.00	30	0	NULL
1004	5004	2024-11-24	2024-11-24 16:00:00	300.00	MacBook Pro	high_risk_region1	200.00	5	0	NULL
1005	5005	2024-11-24	2024-11-24 11:00:00	1100.00	iPad Pro	Chicago	200.00	10	0	NULL

Update the risk level of all daily transaction records according to the following risk control rules: 1. Transactions with a dispute history have a risk level of high. 2. Transactions in high-risk regions have a risk level of high. 3. Transactions with abnormal amounts (exceeding 5 times the daily average) have a risk level of high. 4. Frequent transactions in the last 7 days: a. Transactions > 50 times have a risk level of high. b. Transactions between 20 and 50 times have a risk level of medium. 5. Transactions during non-working hours (2 AM to 4 AM) have a risk level of medium. 6. The default risk level is low.

```

UPDATE transaction_details
SET risk_level = CASE
 -- Transactions with a dispute history or in high-risk regions
 WHEN has_dispute_history = TRUE THEN 'high'
 WHEN transaction_region IN ('high_risk_region1', 'high_risk_region2') THEN 'high'

 -- Abnormal transaction amount
 WHEN transaction_amount > 5 * average_daily_amount THEN 'high'

 -- High transaction frequency in the last 7 days
 WHEN recent_transaction_count > 50 THEN 'high'

```

```

WHEN recent_transaction_count BETWEEN 20 AND 50 THEN 'medium'

-- Transactions during non-working hours
WHEN HOUR(transaction_time) BETWEEN 2 AND 4 THEN 'medium'

-- Default risk level
ELSE 'low'
END
WHERE transaction_date = '2024-11-24';

```

The updated data is as follows:

transaction_id	user_id	transaction_date	transaction_time	transaction_amount	transaction_device	transaction_region	average_daily_amount	recent_transaction_count	has_dispute_history	risk_level
1001	5001	2024-11-24	2024-11-24 14:30:00	100.00	iPhone 12	New York	100.00	10	0	low
1002	5002	2024-11-24	2024-11-24 03:30:00	120.00	iPhone 12	New York	100.00	15	0	medium
1003	5003	2024-11-24	2024-11-24 10:00:00	150.00	Samsung S21	Los Angeles	100.00	30	0	medium
1004	5004	2024-11-24	2024-11-24 16:00:00	300.00	MacBook Pro	high_risk_region1	200.00	5	0	high
1005	5005	2024-11-24	2024-11-24 11:00:00	1100.00	iPad Pro	Chicago	200.00	10	0	high

## More Help

For more detailed syntax on data updates, please refer to the [UPDATE](#) command manual. You can also enter `HELP UPDATE` in the MySQL client command line for more help.

# Updating Data on Unique Key Model

This document introduces how to update data in the Doris unique key model using various load methods.

## Whole Row Update

When loading data into the unique key model using Doris-supported methods like Stream Load, Broker Load, Routine Load, Insert Into, etc., new data is inserted if there is no existing primary key data row. If there is an existing primary key data row, it is updated. This means the load operation in the Doris unique key model works in an “upsert” mode. The process of updating existing records is the same as loading new records by default, so you can refer to the data load documentation for more details.

## Partial Column Update

Partial column update allows you to update specific fields in a table without modifying all fields. You can use the Update statement to perform this operation, which typically involves reading the entire row, updating the desired fields, and writing it back. This read-write transaction is time-consuming and not suitable for large-scale data writing. Doris provides a feature to directly insert or update partial column data in the unique key model load update, bypassing the need to read the entire row first, thus significantly improving update efficiency.

### Note

1. Version 2.0 only supports partial column updates in the Merge-on-Write implementation of the Unique Key.
2. Starting from version 2.0.2, partial column updates are supported using INSERT INTO.
3. Partial column updates are not supported on tables with synchronized materialized views.
4. Partial column updates are not allowed on tables doing schema change.

## Applicable Scenarios

- Real-time dynamic column updates, requiring frequent updates of specific fields in the table. For example, updating fields related to the latest user behavior in a user tag table for real-time analysis and decision-making in advertising/recommendation systems.
- Merging multiple source tables into one large wide table.
- Data correction.

## Usage Example

Assume there is an order table `order_tbl` in Doris, where the order id is the Key column, and the order status and order amount are the Value columns. The data status is as follows:

Order id	Order Amount	Order Status
1	100	Pending Payment

```

+-----+-----+-----+
| order_id | order_amount | order_status |
+-----+-----+-----+
| 1 | 100 | Pending Payment |
+-----+-----+-----+
1 row in set (0.01 sec)

```

After the user clicks to pay, the Doris system needs to change the order status of the order with order id '1' to 'Pending Shipment'.

## Partial Column Update Using Load Methods

### StreamLoad/BrokerLoad/RoutineLoad

Prepare the following CSV file:

```
1,Pending Shipment
```

Add the following header during load:

```
partial_columns:true
```

Specify the columns to be loaded in `columns` (must include all key columns). Below is an example of Stream Load:

```
curl --location-trusted -u root: -H "partial_columns:true" -H "column_separator:," -H
"columns:order_id,order_status" -T /tmp/update.csv http://127.0.0.1:8030/api/db1/order_tbl/_stream_load
```

## INSERT INTO

In all data models, the default behavior of `INSERT INTO` when given partial columns is to write the entire row. To prevent misuse, in the Merge-on-Write implementation, `INSERT INTO` maintains the semantics of whole row UPSERT by default. To enable partial column updates, set the following session variable:

```
SET enable_unique_key_partial_update=true;
INSERT INTO order_tbl (order_id, order_status) VALUES (1, 'Pending Shipment');
```

Note that the session variable `enable_insert_strict` defaults to `true`, enabling strict mode by default. In strict mode, partial column updates do not allow updating non-existent keys. To insert non-existent keys using the insert statement for partial column updates, set `enable_unique_key_partial_update` to `true` and `enable_insert_strict` to `false`.

## Flink Connector

If using Flink Connector, add the following configuration:

```
'sink.properties.partial_columns' = 'true',
```

Specify the columns to be loaded in `sink.properties.column` (must include all key columns).

## Update Result

The result after the update is as follows:

```
+-----+-----+-----+
| order_id | order_amount | order_status |
+-----+-----+-----+
| 1 | 100 | Pending Shipment |
+-----+-----+-----+
1 row in set (0.01 sec)
```

## Usage Notes

Since the Merge-on-Write implementation needs to complete the entire row of data during writing to ensure optimal query performance, using it for partial column updates may decrease partial load performance.

Performance optimization suggestions:

- Use SSDs equipped with NVMe or high-speed SSD cloud disks, as completing data will read a large amount of historical data, generating high read IOPS and throughput.
- Enabling row storage can reduce the IOPS generated when completing data, significantly improving load performance. Enable row storage by setting the following property when creating a table:

```
"store_row_column" = "true"
```

Currently, all rows in the same batch data writing task (whether a load task or INSERT INTO) can only update the same columns. To update data with different columns, write in different batches.

Future versions will support flexible column updates, allowing users to update different columns for each row in the same batch load.

# Updating Data on Aggregate Key Model

---

This document primarily introduces how to update the Doris Aggregate model based on data load.

## Whole Row Update

When loading data into the Aggregate model table using Doris-supported methods such as Stream Load, Broker Load, Routine Load, Insert Into, etc., the new values will be aggregated with the old values according to the column's aggregation function to produce new aggregated values. This value may be generated at the time of insertion or during asynchronous compaction, but users will get the same return value when querying.

## Partial Column Update of Aggregate Model

The Aggregate table is mainly used in pre-aggregation scenarios rather than data update scenarios, but partial column updates can be achieved by setting the aggregation function to `REPLACE_IF_NOT_NULL`.

### Create Table

Set the aggregation function of the fields that need to be updated to `REPLACE_IF_NOT_NULL`.

```
CREATE TABLE order_tbl (
 order_id int(11) NULL,
 order_amount int(11) REPLACE_IF_NOT_NULL NULL,
 order_status varchar(100) REPLACE_IF_NOT_NULL NULL
) ENGINE=OLAP
AGGREGATE KEY(order_id)
COMMENT 'OLAP'
DISTRIBUTED BY HASH(order_id) BUCKETS 1
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

### Data Insertion

Whether it is Stream Load, Broker Load, Routine Load, or `INSERT INTO`, directly write the data of the fields to be updated.

### Example

Similar to the previous examples, the corresponding Stream Load command is (no additional header required):

```
$ cat update.csv

1,To be shipped

curl --location-trusted -u root: -H "column_separator:," -H "columns:order_id,order_status" -T ./update.csv
http://127.0.0.1:8030/api/db1/order_tbl/_stream_load
```

The corresponding `INSERT INTO` statement is (no additional session variable settings required):

```
INSERT INTO order_tbl (order_id, order_status) values (1,'Shipped');
```

## Notes on Partial Column Updates

The Aggregate Key model does not perform any additional processing during the write process, so the write performance is not affected and is the same as normal data load. However, the cost of aggregation during query is relatively high, and the typical aggregation query performance is 5-10 times lower than the Merge-on-Write implementation of the Unique Key model.

Since the REPLACE\_IF\_NOT\_NULL aggregation function only takes effect when the value is not NULL, users cannot change a field value to NULL.

# Concurrency Control for Updates in the Primary Key Model

---

## Overview

Doris employs Multi-Version Concurrency Control (MVCC) to handle concurrent updates. Each data write operation is assigned a write transaction, ensuring atomicity (i.e., the write operation either fully succeeds or fully fails). Upon committing the write transaction, the system assigns it a version number. In the Unique Key model, when loading data multiple times, if there are duplicate primary keys, Doris determines the overwrite order based on the version number: data with a higher version number will overwrite data with a lower version number.

In some scenarios, users may need to adjust the effective order of data by specifying a sequence column in the table creation statement. For example, when synchronizing data to Doris concurrently through multiple threads, data from different threads may arrive out of order. In this case, old data arriving later may incorrectly overwrite new data. To solve this problem, users can assign a lower sequence value to old data and a higher sequence value to new data, allowing Doris to correctly determine the update order based on the user-provided sequence values.

Additionally, the UPDATE statement differs significantly from updates implemented through data loads at the underlying mechanism level. The UPDATE operation involves two steps: reading the data to be updated from the database and writing the updated data. By default, the UPDATE statement provides transaction capabilities with Serializable isolation level through table-level locks, meaning multiple UPDATE operations can only be executed serially. Users can also bypass this restriction by adjusting the configuration, as detailed in the following sections.

## UPDATE Concurrency Control

By default, concurrent UPDATE operations on the same table are not allowed.

The main reason is that Doris currently supports row updates, which means that even if the user declares `SET v2 = 1`, all other value columns will also be overwritten (even if the values have not changed).

This can lead to a problem where if two UPDATE operations update the same row simultaneously, the behavior may be indeterminate, potentially resulting in dirty data.

However, in practical applications, if users can ensure that concurrent updates do not operate on the same row simultaneously, they can manually enable concurrent updates. By modifying the FE configuration `enable_concurrent_update`, setting this configuration value to `true` will disable transaction guarantees for update commands.

## Sequence Column

The Unique model is mainly for scenarios requiring unique primary keys, ensuring the uniqueness constraint of the primary key. The replacement order of data loaded in the same batch or different batches is not

guaranteed. Without a guaranteed replacement order, the specific data ultimately loaded into the table is uncertain.

To solve this problem, Doris supports sequence columns. By specifying a sequence column during loading, data with the same key column is replaced based on the sequence column value, with larger values replacing smaller ones, and vice versa. This method allows users to control the replacement order.

In implementation, Doris adds a hidden column **DORIS\_SEQUENCE\_COL**, whose type is specified by the user during table creation. The specific value of this column is determined during data loading, and the effective row for the same key column is decided based on this value.

#### Note

The sequence column currently only supports the Unique model.

## Enabling Sequence Column Support

When creating a new table, if `function_column.sequence_col` or `function_column.sequence_type` is set, the new table will support sequence columns.

For a table that does not support sequence columns, you can enable this feature using the following statement:

```
ALTER TABLE example_db.my_table ENABLE FEATURE "SEQUENCE_LOAD" WITH PROPERTIES
("function_column.sequence_type" = "Date").
```

To check if a table supports sequence columns, you can set a session variable to display hidden columns `SET show_hidden_columns=true`, then use `desc tablename`. If the output includes the `__DORIS_SEQUENCE_COL__` column, it is supported; otherwise, it is not.

## Usage Example

Below is an example of using Stream Load:

### 1. Create a table supporting sequence columns

Create a unique model `test_table` and map the sequence column to the `modify_date` column.

```
CREATE TABLE test.test_table
(
 user_id bigint,
 date date,
 group_id bigint,
 modify_date date,
 keyword VARCHAR(128)
)
UNIQUE KEY(user_id, date, group_id)
DISTRIBUTED BY HASH (user_id) BUCKETS 32
PROPERTIES(
 "function_column.sequence_col" = 'modify_date',
 "replication_num" = "1",
 "in_memory" = "false"
);
```

The `sequence_col` specifies the mapping of the sequence column to a column in the table. This column can be of integer or date/time type (DATE, DATETIME) and cannot be changed after creation.

The table structure is as follows:

```
MySQL> desc test_table;
```

Field	Type	Null	Key	Default	Extra
user_id	BIGINT	No	true	NULL	
date	DATE	No	true	NULL	
group_id	BIGINT	No	true	NULL	
modify_date	DATE	No	false	NULL	REPLACE
keyword	VARCHAR(128)	No	false	NULL	REPLACE

In addition to specifying the sequence column through column mapping, Doris also supports creating a sequence column based on a specified type. This method does not require a column in the schema for mapping. The syntax is as follows:

```
PROPERTIES (
 "function_column.sequence_type" = 'Date',
);
```

The `sequence_type` specifies the type of the sequence column, which can be integer or date/time type (DATE, DATETIME).

## 2. Load Data:

Using column mapping (`function_column.sequence_col`) to specify the sequence column does not require modifying any parameters. Below is an example of loading data using Stream Load:

```
1 2020-02-22 1 2020-02-21 a
1 2020-02-22 1 2020-02-22 b
1 2020-02-22 1 2020-03-05 c
1 2020-02-22 1 2020-02-26 d
1 2020-02-22 1 2020-02-23 e
1 2020-02-22 1 2020-02-24 b
```

Stream load command:

```
curl --location-trusted -u root: -T testData http://host:port/api/test/test_table/_stream_load
```

Result:

```
MySQL> select * from test_table;
```

user_id	date	group_id	modify_date	keyword
1	2020-02-22	1	2020-03-05	c

In this load job, the value '2020-03-05' in the sequence column (modify\_date) is the largest, so the keyword column retains 'c'.

If the sequence column is specified using function\_column.sequence\_col during table creation, the sequence column mapping must be specified during load.

## 1. Stream Load

In Stream Load, specify the sequence column mapping in the header:

```
curl --location-trusted -u root -H "columns: k1,k2,source_sequence,v1,v2" -H "function_column.sequence_col:source_sequence" -T testData http://host:port/api/testDb/testTbl/_stream_load
```

## 2. Broker Load

Set the hidden column mapping in the ORDER BY clause:

```
LOAD LABEL db1.label1
(
 DATA INFILE("hdfs://host:port/user/data/*/test.txt")
 INTO TABLE `tbl1`
 COLUMNS TERMINATED BY ","
 (k1,k2,source_sequence,v1,v2)
 ORDER BY source_sequence
)
WITH BROKER 'broker'
(
 "username"="user",
 "password"="pass"
)
PROPERTIES
(
 "timeout" = "3600"
);
```

## 3. Routine Load

The mapping method is the same as above. Example:

```
CREATE ROUTINE LOAD example_db.test1 ON example_tbl
[WITH MERGE|APPEND|DELETE]
COLUMNS(k1, k2, source_sequence, v1, v2),
WHERE k1 > 100 and k2 like "%doris%"
[ORDER BY source_sequence]
PROPERTIES
(
 "desired_concurrent_number"="3",
 "max_batch_interval" = "20",
 "max_batch_rows" = "300000",
 "max_batch_size" = "209715200",
 "strict_mode" = "false"
)
FROM KAFKA
(
 "kafka_broker_list" = "broker1:9092,broker2:9092,broker3:9092",
 "kafka_topic" = "my_topic",
 "kafka_partitions" = "0,1,2,3",
```

```
"kafka_offsets" = "101,0,0,200"
);
```

### 3. Ensuring Replacement Order

After completing the above steps, load the following data:

```
1 2020-02-22 1 2020-02-22 a
1 2020-02-22 1 2020-02-23 b
```

Query data:

```
MySQL [test]> select * from test_table;
+-----+-----+-----+-----+-----+
| user_id | date | group_id | modify_date | keyword |
+-----+-----+-----+-----+-----+
| 1 | 2020-02-22 | 1 | 2020-03-05 | c |
+-----+-----+-----+-----+-----+
```

In this load, the sequence column value '2020-03-05' is the largest, so the keyword column retains 'c'.

### 4. Try Loading the Following Data

```
1 2020-02-22 1 2020-02-22 a
1 2020-02-22 1 2020-03-23 w
```

Query data:

```
MySQL [test]> select * from test_table;
+-----+-----+-----+-----+-----+
| user_id | date | group_id | modify_date | keyword |
+-----+-----+-----+-----+-----+
| 1 | 2020-02-22 | 1 | 2020-03-23 | w |
+-----+-----+-----+-----+-----+
```

This time, the data in the table is replaced. In summary, during the load process, the sequence column values of all batches are compared, and the record with the largest value is loaded into the Doris table.

### Note

1. To prevent misuse, in Stream Load/Broker Load load tasks and row update insert statements, users must explicitly specify the sequence column (unless the default value of the sequence column is CURRENT\_TIMESTAMP), otherwise, the following error message will be received:

```
Table test_tbl has sequence column, need to specify the sequence column
```

2. When you use the Insert statement to insert data, you must display the specified sequence column; otherwise, the preceding exception is reported. In order to facilitate the use of Doris in some scenarios (table replication, internal data migration, etc.), Doris can be controlled by the session parameter to close the check constraint on the sequence column:

```
set require_sequence_in_insert = false;
```

3. Since version 2.0, Doris supports partial column update capability for Unique Key tables with Merge-on-Write implementation. In partial column update loads, users can update only a portion of the columns each time, so it is not necessary to include the sequence column. If the load task submitted by the user includes the sequence column, the behavior is unaffected; if the load task does not include the sequence column, Doris will use the sequence column from the matching historical data as the value of the sequence column for the updated row. If there is no matching key column in the historical data, null or the default value will be used.
4. During concurrent loads, Doris uses the MVCC mechanism to ensure data correctness. If two batches of data loads update different columns of the same key, the load task with the higher system version will use the data row written by the lower version load task to fill in the same key after the lower version load task succeeds.

# Delete Overview

---

In Apache Doris, the delete operation is essential for managing and cleaning data to meet the flexible needs of users in large-scale data analysis scenarios.

Doris offers a variety of delete functionalities, including DELETE statements, delete sign, partition deletion, full table deletion, and atomic overwrite using temporary partitions. The following sections will detail each feature:

## DELETE Statement

The DELETE statement is the most commonly used method for deleting data and supports all table models. Users can use it to delete data that meets specific conditions.

The syntax of the DELETE statement is as follows:

```
DELETE FROM table_name WHERE condition;
```

While the DELETE statement can handle most deletion needs, it may not be the most efficient in some scenarios. To address various deletion requirements flexibly and efficiently, Doris also provides the following methods.

## Truncate Partition

In Doris, managing data through date partitions and other methods is common. Many users only need to retain data for a recent period (e.g., 7 days). For expired data partitions, the truncate partition feature can be used for efficient deletion.

Compared to the DELETE statement, truncate partition only requires modifying some partition metadata to complete the deletion, making it the best method in this scenario.

The syntax of partition deletion is as follows:

```
TRUNCATE TABLE tbl PARTITION(p1, p2);
```

## Truncate Table

Truncate table is suitable for quickly clearing a table while retaining its structure, such as when redoing data in offline analysis scenarios.

The syntax of full truncate table is as follows:

```
TRUNCATE TABLE table_name;
```

## Delete Sign

Data deletion can be considered a type of data update. Therefore, on the primary key model (Unique Key) with update capabilities, users can use the delete sign feature to perform delete operations as data updates.

For example, in CDC data synchronization scenarios, the CDC program can mark a DELETE operation binlog with a delete sign. When this data is written to Doris, the corresponding primary key will be deleted.

This method can perform batch deletion of a large number of primary keys, which is more efficient than the DELETE statement.

The delete sign is an advanced feature and is more complex to use compared to the previous methods. For detailed usage, please refer to the document [Batch Deletion](#).

## Atomic Overwrite Using Temporary Partitions

In some cases, users want to rewrite the data of a partition. However, if the data is deleted and then loaded, there will be a period when the data is unavailable. In this case, users can first create a corresponding temporary partition, load the new data into the temporary partition, and then replace the original partition atomically. For detailed usage, please refer to the document [Atomic Table Replacement](#).

## Precautions

1. The delete operation will generate new data versions, so frequent deletions may increase the number of versions, thereby affecting query performance.
2. Deleted data will still occupy storage until merge and compression are completed, so the delete operation itself will not immediately reduce storage usage.

# Deleting Data with DELETE Command

---

The DELETE statement removes data from a specified table or partition based on conditions through the MySQL protocol. It supports specifying the data to be deleted using simple predicate combinations and also supports using the USING clause to join multiple tables for deletion on primary key tables.

## Delete by Specifying Filter Predicates

```
DELETE FROM table_name [table_alias]
[PARTITION partition_name | PARTITIONS (partition_name [, partition_name])]
WHERE column_name op { value | value_list } [AND column_name op { value | value_list } ...];
```

### Required Parameters

- `table_name`: The table from which data needs to be deleted.
- `column_name`: A column belonging to `table_name`.
- `op`: Logical comparison operators, including: `=`, `>`, `<`, `>=`, `<=`, `!=`, `in`, `not in`.
- `value | value_list`: The value or list of values for logical comparison.

### Optional Parameters

- `PARTITION partition_name | PARTITIONS (partition_name [, partition_name])`: Specifies the partition name where the data deletion is to be executed. If the table does not have this partition, an error will be reported.
- `table_alias`: Alias for the table.

### Usage Restrictions

- When using the Aggregate table model, conditions can only be specified on Key columns. If the selected Key column does not exist in a Rollup, deletion cannot be performed.
- For partitioned tables, partitions need to be specified. If not specified, Doris will infer the partition from the conditions.
  - Doris cannot infer the partition from the conditions in two cases:
    1. The conditions do not include partition columns.
    2. The `op` of the partition column is not `in`.
  - When the partitioned table is not a Unique table, and it does not specify a partition or cannot infer the partition from the conditions, the session variable `delete_without_partition` needs to be set to `true`, and the delete operation will apply to all partitions.

## Examples

### 1. Delete rows in partition p1 of my\_table where the value of column k1 is 3

```
DELETE FROM my_table PARTITION p1
WHERE k1 = 3;
```

### 2. Delete rows in partition p1 of my\_table where the value of column k1 is greater than or equal to 3 and the value of column status is “outdated”

```
DELETE FROM my_table PARTITION p1
WHERE k1 >= 3 AND status = "outdated";
```

### 3. Delete rows in partitions p1 and p2 of my\_table where the value of column k1 is greater than or equal to 3 and the value of column dt is between “2024-10-01” and “2024-10-31”

```
DELETE FROM my_table PARTITIONS (p1, p2)
WHERE k1 >= 3 AND dt >= "2024-10-01" AND dt <= "2024-10-31";
```

## Delete Using the USING Clause

In some scenarios, users need to join multiple tables to accurately determine the data to be deleted. In such cases, the USING clause is very useful. The syntax is as follows:

```
DELETE FROM table_name [table_alias]
[PARTITION partition_name | PARTITIONS (partition_name [, partition_name])]
[USING additional_tables]
WHERE condition
```

### Required Parameters

- `table_name`: The table from which data needs to be deleted.
- `WHERE condition`: Specifies the condition for selecting the rows to be deleted.

### Optional Parameters

- `PARTITION partition_name | PARTITIONS (partition_name [, partition_name])`: Specifies the partition name where the data deletion is to be executed. If the table does not have this partition, an error will be reported.
- `table_alias`: Alias for the table.

### Notes

- This form can only be used on UNIQUE KEY model tables.

## Example

Using the join result of tables t2 and t3, delete data from t1. The table to be deleted only supports the unique model.

```
-- Create tables t1, t2, t3
CREATE TABLE t1
 (id INT, c1 BIGINT, c2 STRING, c3 DOUBLE, c4 DATE)
UNIQUE KEY (id)
DISTRIBUTED BY HASH (id)
PROPERTIES('replication_num'='1', "function_column.sequence_col" = "c4");

CREATE TABLE t2
 (id INT, c1 BIGINT, c2 STRING, c3 DOUBLE, c4 DATE)
DISTRIBUTED BY HASH (id)
PROPERTIES('replication_num'='1');

CREATE TABLE t3
 (id INT)
DISTRIBUTED BY HASH (id)
PROPERTIES('replication_num'='1');

-- Insert data
INSERT INTO t1 VALUES
 (1, 1, '1', 1.0, '2000-01-01'),
 (2, 2, '2', 2.0, '2000-01-02'),
 (3, 3, '3', 3.0, '2000-01-03');

INSERT INTO t2 VALUES
 (1, 10, '10', 10.0, '2000-01-10'),
 (2, 20, '20', 20.0, '2000-01-20'),
 (3, 30, '30', 30.0, '2000-01-30'),
 (4, 4, '4', 4.0, '2000-01-04'),
 (5, 5, '5', 5.0, '2000-01-05');

INSERT INTO t3 VALUES
 (1),
 (4),
 (5);

-- Delete data from t1
DELETE FROM t1
 USING t2 INNER JOIN t3 ON t2.id = t3.id
 WHERE t1.id = t2.id;
```

The expected result is to delete the row in table t1 where id is 1.

id	c1	c2	c3	c4
2	2	2	2.0	2000-01-02
3	3	3	3.0	2000-01-03

## Related Configuration

### Timeout Configuration

- `insert_timeout`: Since the delete operation is an SQL command and is considered a special load, the delete statement is affected by the `insert_timeout` value in the Session. You can increase the timeout by `SET insert_timeout = xxx`, where the unit is seconds.

## IN Predicate Configuration

- `max_allowed_in_element_num_of_delete`: If the user needs to use a large number of elements in the in predicate, this item can be adjusted to increase the allowed element limit. The default value is 1024.

## View History

Users can view the history of completed delete records using the `SHOW DELETE` statement.

The syntax is as follows:

```
SHOW DELETE [FROM db_name]
```

Example:

```
mysql> show delete from test_db;
```

TableName	PartitionName	CreateTime	DeleteCondition	State
empty_tbl	p3	2020-04-15 23:09:35	k1 EQ "1"	FINISHED
test_tbl	p4	2020-04-15 23:09:53	k1 GT "80"	FINISHED

2 rows in set (0.00 sec)

## Performance Recommendations

1. On detail tables (Duplicate Key) and aggregate tables (Aggregate Key), the delete operation executes quickly, but a large number of delete operations in a short period will affect query performance.
2. On primary key tables (Unique Key), the delete operation is converted into an `INSERT INTO` statement. When deleting a large range, the execution speed is slow, but a large number of delete operations in a short period will not significantly affect query performance.

## Syntax

For detailed delete syntax, refer to the [DELETE](#) syntax manual.

# Batch Deletion Based on Load

---

## Batch Deletion Based on Load

The delete operation is a special form of data update. In the primary key model (Unique Key) table, Doris supports deletion by adding a delete sign when loading data.

Compared to the DELETE statement, using delete signs offers better usability and performance in the following scenarios:

1. **CDC Scenario:** When synchronizing data from an OLTP database to Doris, Insert and Delete operations in the binlog usually appear alternately. The DELETE statement cannot efficiently handle these operations. Using delete signs allows Insert and Delete operations to be processed uniformly, simplifying the CDC code for writing to Doris and improving data load and query performance.
2. **Batch Deletion of Specified Primary Keys:** If a large number of primary keys need to be deleted, using the DELETE statement is inefficient. Each execution of DELETE generates an empty rowset to record the delete condition and produces a new data version. Frequent deletions or too many delete conditions can severely affect query performance.

## Working Principle of Delete Signs

### Principle Explanation

- **Table Structure:** The delete sign is stored as a hidden column `__DORIS_DELETE_SIGN__` in the primary key table. When the value of this column is 1, it indicates that the delete sign is effective.
- **Data Load:** Users can specify the mapping condition of the delete sign column in the load task. The usage varies for different load tasks, as detailed in the syntax explanation below.
- **Query:** During the query, Doris FE automatically adds the filter condition `__DORIS_DELETE_SIGN__ != true` in the query plan to filter out data with a delete sign value of 1.
- **Data Compaction:** Doris's background data compaction periodically cleans up data with a delete sign value of 1.

### Data Example

#### Table Structure

Create an example table:

```
CREATE TABLE example_table (
 id BIGINT NOT NULL,
 value STRING
)
UNIQUE KEY(id)
DISTRIBUTED BY HASH(id) BUCKETS 10
PROPERTIES (
 "replication_num" = "3"
);
```

Use the session variable `show_hidden_columns` to view hidden columns:

```
mysql> set show_hidden_columns=true;

mysql> desc example_table;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| id | bigint | No | true | NULL | |
| value | text | Yes | false | NULL | NONE |
| __DORIS_DELETE_SIGN__ | tinyint | No | false | 0 | NONE |
| __DORIS_VERSION_COL__ | bigint | No | false | 0 | NONE |
+-----+-----+-----+-----+-----+-----+
```

## Data Load

The table has the following existing data:

```
+-----+-----+
| id | value |
+-----+-----+
| 1 | foo |
| 2 | bar |
+-----+-----+
```

Insert a delete sign for id 1 (this is only for principle demonstration, not introducing various methods of using delete signs in load):

```
mysql> insert into example_table (id, __DORIS_DELETE_SIGN__) values (1, 1);
```

## Query

Directly view the data, and you can find that the record with id 1 has been deleted:

```
mysql> select * from example_table;
+-----+-----+
| id | value |
+-----+-----+
| 2 | bar |
+-----+-----+
```

Use the session variable `show_hidden_columns` to view hidden columns, and you can see that the row with id 1 has not been actually deleted. Its hidden column `__DORIS_DELETE_SIGN__` value is 1 and is filtered out during the query:

```
mysql> set show_hidden_columns=true;
mysql> select * from example_table;
+-----+-----+-----+-----+
| id | value | __DORIS_DELETE_SIGN__ | __DORIS_VERSION_COL__ |
+-----+-----+-----+-----+
| 1 | NULL | 1 | 3 |
+-----+-----+-----+-----+
```

	2	bar		0		2	
+	-----	+	-----	+	-----	+	-----

## Syntax Explanation

Different load types have different syntax for setting delete signs. Below are the usage syntax for delete signs in various load types.

### Load Merge Type Selection

There are several merge types when loading data:

1. **APPEND**: All data is appended to the existing data.
2. **DELETE**: Delete all rows with the same key column values as the loaded data.
3. **MERGE**: Decide whether to APPEND or DELETE based on the DELETE ON condition.

### Stream Load

The Stream Load syntax is to add a field for setting the delete sign column in the header's columns field, for example: `-H "columns: k1, k2, label_c3" -H "merge_type: [MERGE|APPEND|DELETE]" -H "delete: label_c3=1"`.

For usage examples of Stream Load, please refer to the "Specify merge\_type for Delete Operation" and "Specify merge\_type for Merge Operation" sections in the [Stream Load Manual](#).

### Broker Load

The Broker Load syntax is to set the delete sign column field in PROPERTIES, as follows:

```
LOAD LABEL db1.label1
(
 [MERGE|APPEND|DELETE] DATA INFILE("hdfs://abc.com:8888/user/palo/test/ml/file1")
 INTO TABLE tbl1
 COLUMNS TERMINATED BY ","
 (tmp_c1,tmp_c2, label_c3)
 SET
 (
 id=tmp_c2,
 name=tmp_c1,
)
 [DELETE ON label_c3=true]
)
WITH BROKER 'broker'
(
 "username"="user",
 "password"="pass"
)
PROPERTIES
(
 "timeout" = "3600"
);
```

## Routine Load

The Routine Load syntax is to add a mapping in the columns field, with the same mapping method as above, as follows:

```
CREATE ROUTINE LOAD example_db.test1 ON example_tbl
[WITH MERGE|APPEND|DELETE]
COLUMNS(k1, k2, k3, v1, v2, label),
WHERE k1 100 and k2 like "%doris%"
[DELETE ON label=true]
PROPERTIES
(
 "desired_concurrent_number"="3",
 "max_batch_interval" = "20",
 "max_batch_rows" = "300000",
 "max_batch_size" = "209715200",
 "strict_mode" = "false"
)
FROM KAFKA
(
 "kafka_broker_list" = "broker1:9092,broker2:9092,broker3:9092",
 "kafka_topic" = "my_topic",
 "kafka_partitions" = "0,1,2,3",
 "kafka_offsets" = "101,0,0,200"
);
```

# Deleting Data with TRUNCATE Command

---

## Truncate

Use this statement to clear data from a specified table and its partitions.

### Syntax

```
TRUNCATE TABLE [db.]tbl [PARTITION(p1, p2, ...)];
```

- This statement clears the data but retains the table or partition structure.
- Unlike DELETE, TRUNCATE only performs metadata operations, making it faster and not affecting query performance.
- Data removed by this operation cannot be recovered.
- The table status must be NORMAL, and there should be no ongoing SCHEMA CHANGE operations.
- This command may cause ongoing import tasks to fail.

## Examples

### 1. Clear the table tbl in the example\_db database

```
TRUNCATE TABLE example_db.tbl;
```

### 2. Clear the p1 and p2 partitions of the table tbl

```
TRUNCATE TABLE tbl PARTITION(p1, p2);
```

# Replacing Atomic Table

---

Doris supports atomic replacement operations between two tables, applicable only to OLAP tables.

## Applicable Scenarios

Sometimes, users need to rewrite table data, but deleting and then importing the data would result in a period of unavailability. In such cases, users can create a new table with the same structure using the `CREATE TABLE LIKE` statement, import the new data into the new table, and then perform an atomic replacement of the old table. For partition-level atomic overwrite operations, refer to the [temporary partition documentation](#).

## Syntax

```
ALTER TABLE [db.]tbl1 REPLACE WITH TABLE tbl2
[PROPERTIES('swap' = 'true')];
```

Replace table `tbl1` with table `tbl2`.

If the `swap` parameter is `true`, after the replacement, the data in `tbl1` will be the original data in `tbl2`, and the data in `tbl2` will be the original data in `tbl1`, meaning the data in the two tables will be swapped.

If the `swap` parameter is `false`, after the replacement, the data in `tbl1` will be the original data in `tbl2`, and `tbl2` will be deleted.

## Principle

The table replacement function turns the following set of operations into an atomic operation.

Assuming table `A` is replaced with table `B`, and `swap` is `true`, the operations are as follows:

1. Rename table `B` to table `A`.
2. Rename table `A` to table `B`.

If `swap` is `false`, the operations are as follows:

1. Delete table `A`.
2. Rename table `B` to table `A`.

## Notes

- If the `swap` parameter is `false`, the replaced table (table `A`) will be deleted and cannot be recovered.
- The replacement operation can only occur between two OLAP tables and does not check if the table structures are consistent.
- The replacement operation will not change the original permission settings, as permission checks are based on table names.

# Temporary Partition

---

Apache Doris supports adding temporary partitions to partitioned tables. Temporary partitions differ from regular partitions in that they are not retrieved by standard queries and can only be accessed through specific query statements.

- Temporary partition columns must match those of regular partitions and cannot be modified.
- Temporary partition ranges cannot overlap with each other, but they can overlap with regular partition ranges.
- Temporary partition names must be unique and cannot duplicate regular partition names or other temporary partition names.

## Use Cases

Temporary partitions are primarily used for:

- **Atomic overwrite operations:** You can rewrite partition data without losing data between deletion and import operations. Create a temporary partition, import new data into it, then atomically replace the original partition through a replace operation. For atomic overwrite operations on non-partitioned tables, see the [replace table documentation](#).
- **Bucket count modification:** If an inappropriate bucket count was used when creating a partition, you can create a new temporary partition with the desired bucket count. Import the regular partition data into the temporary partition using the `INSERT INTO` command, then atomically replace the original partition through a replace operation.
- **Partition merging or splitting:** You can modify partition ranges, such as merging two partitions or splitting a large partition into multiple smaller ones. Create a new temporary partition, import the regular partition data using the `INSERT INTO` command, then atomically replace the original partition through a replace operation.

## Adding Temporary Partitions

Use the `ALTER TABLE ADD TEMPORARY PARTITION` statement to add temporary partitions:

```
ALTER TABLE tbl1 ADD TEMPORARY PARTITION tp1 VALUES LESS THAN("2020-02-01");

ALTER TABLE tbl2 ADD TEMPORARY PARTITION tp1 VALUES [("2020-01-01"), ("2020-02-01"));

ALTER TABLE tbl1 ADD TEMPORARY PARTITION tp1 VALUES LESS THAN("2020-02-01")
("replication_num" = "1")
DISTRIBUTED BY HASH(k1) BUCKETS 5;

ALTER TABLE tbl3 ADD TEMPORARY PARTITION tp1 VALUES IN ("Beijing", "Shanghai");

ALTER TABLE tbl4 ADD TEMPORARY PARTITION tp1 VALUES IN ((1, "Beijing"), (1, "Shanghai"));

ALTER TABLE tbl3 ADD TEMPORARY PARTITION tp1 VALUES IN ("Beijing", "Shanghai")
```

```
("replication_num" = "1")
DISTRIBUTED BY HASH(k1) BUCKETS 5;
```

## Dropping Temporary Partitions

Use the ALTER TABLE DROP TEMPORARY PARTITION statement to drop temporary partitions:

```
ALTER TABLE tbl1 DROP TEMPORARY PARTITION tp1;
```

## Replacing Regular Partitions

Use the ALTER TABLE REPLACE PARTITION statement to replace regular partitions with temporary partitions:

```
ALTER TABLE tbl1 REPLACE PARTITION (p1) WITH TEMPORARY PARTITION (tp1);

ALTER TABLE tbl1 REPLACE PARTITION (p1, p2) WITH TEMPORARY PARTITION (tp1, tp2, tp3);

ALTER TABLE tbl1 REPLACE PARTITION (p1, p2) WITH TEMPORARY PARTITION (tp1, tp2)
PROPERTIES (
 "strict_range" = "false",
 "use_temp_partition_name" = "true"
);
```

The replace operation supports two optional parameters:

### 1. strict\_range

**Default value:** true

**For Range partitions:** When true, the union of all replaced regular partition ranges must exactly match the union of the replacing temporary partition ranges. When false, only ensure that the new regular partition ranges don't overlap after replacement.

**For List partitions:** This parameter is always true. The enumeration values of all replaced regular partitions must exactly match the enumeration values of the replacing temporary partitions.

### Example 1: Range partitions with matching unions

```
-- The range of partitions p1, p2, p3 to be replaced (=> union):
[10, 20), [20, 30), [40, 50) => [10, 30), [40, 50)

-- The range of replacing partitions tp1, tp2 (=> union):
[10, 30), [40, 45), [45, 50) => [10, 30), [40, 50)

-- Range unions match, so tp1 and tp2 can replace p1, p2, p3.
```

### Example 2: Range partitions with non-matching unions

```
-- The range of partition p1 to be replaced (=> union):
[10, 50) => [10, 50)

-- The range of replacing partitions tp1, tp2 (=> union):
```

```
[10, 30), [40, 50) => [10, 30), [40, 50)
```

-- The union of ranges is not the same. If `strict_range` is true, `tp1` and `tp2` cannot replace `p1`. If it is false, and the ranges of the two partitions after replacement `[10, 30)`, `[40, 50)` do not overlap with other regular partitions, they can replace `p1`.

### Example 3: List partitions with matching unions

-- The enumeration values of partitions `p1`, `p2` to be replaced ( $\Rightarrow$  union):

```
(1, 2, 3), (4, 5, 6) => (1, 2, 3, 4, 5, 6)
```

-- The enumeration values of replacing partitions `tp1`, `tp2`, `tp3` ( $\Rightarrow$  union):

```
(1, 2, 3), (4), (5, 6) => (1, 2, 3, 4, 5, 6)
```

-- Enumeration unions match, so `tp1`, `tp2`, `tp3` can replace `p1`, `p2`.

### Example 4: Multi-column list partitions with matching unions

-- The enumeration values of partitions `p1`, `p2`, `p3` to be replaced ( $\Rightarrow$  union):

```
((("1","beijing"), ("1", "shanghai")), (("2","beijing"), ("2", "shanghai")), (("3","beijing"), ("3",
"shanghai"))) => ((("1","beijing"), ("1", "shanghai"), ("2","beijing"), ("2", "shanghai"), ("3","beijing"),
("3", "shanghai")))
```

-- The enumeration values of replacing partitions `tp1`, `tp2` ( $\Rightarrow$  union):

```
((("1","beijing"), ("1", "shanghai")), (("2","beijing"), ("2", "shanghai"), ("3","beijing"), ("3",
"shanghai"))) => ((("1","beijing"), ("1", "shanghai"), ("2","beijing"), ("2", "shanghai"), ("3","beijing"),
("3", "shanghai")))
```

-- Enumeration unions match, so `tp1`, `tp2` can replace `p1`, `p2`, `p3`.

## 2. use\_temp\_partition\_name

**Default value:** false

When false and the number of partitions to replace equals the number of replacing partitions, partition names remain unchanged after replacement.

When true, partition names after replacement become the names of the replacing partitions.

### Example 1: Same partition count

```
ALTER TABLE tbl1 REPLACE PARTITION (p1) WITH TEMPORARY PARTITION (tp1);
```

- With `use_temp_partition_name` defaulting to false, the partition name remains `p1` after replacement, but data and properties are replaced with those of `tp1`.
- With `use_temp_partition_name` set to true, the partition name becomes `tp1` after replacement, and `p1` no longer exists.

### Example 2: Different partition counts

```
ALTER TABLE tbl1 REPLACE PARTITION (p1, p2) WITH TEMPORARY PARTITION (tp1);
```

- With `use_temp_partition_name` defaulting to `false`, but since partition counts differ, this parameter is ignored. After replacement, the partition name becomes `tp1`, and `p1` and `p2` no longer exist.

\*\*\*\*Important: **After successful partition replacement, the replaced partitions are permanently deleted and cannot be recovered.**

## Importing Data into Temporary Partitions

The syntax for importing data into temporary partitions varies slightly depending on the import method:

```
INSERT INTO tbl TEMPORARY PARTITION(tp1, tp2, ...) SELECT

curl --location-trusted -u root: -H "label:123" -H "temporary_partitions: tp1, tp2, ..." -T testData
http://host:port/api/testDb/testTbl/_stream_load

LOAD LABEL example_db.label1
(
 DATA INFILE("hdfs://hdfs_host:hdfs_port/user/palo/data/input/file")
 INTO TABLE my_table
 TEMPORARY PARTITION (tp1, tp2, ...)
 ...
)
WITH BROKER hdfs ("username"="hdfs_user", "password"="hdfs_password");

CREATE ROUTINE LOAD example_db.test1 ON example_tbl
COLUMNS(k1, k2, k3, v1, v2, v3 = k1 * 100),
TEMPORARY PARTITIONS(tp1, tp2, ...),
WHERE k1 > 100
PROPERTIES
(...)
FROM KAFKA
(...);
```

## Querying Temporary Partitions

```
SELECT ... FROM
tbl1 TEMPORARY PARTITION(tp1, tp2, ...)
JOIN
tbl2 TEMPORARY PARTITION(tp1, tp2, ...)
ON ...
WHERE ...;
```

## Interaction with Other Operations

### DROP Operations

- **Database/Table DROP:** After dropping a database or table, you can recover it using the `Recover` command (within time limits), but temporary partitions are not recovered.
- **Regular Partition DROP:** After dropping a regular partition, you can recover it using the `Recover` command (within time limits). This operation doesn't affect temporary partitions.

- **Temporary Partition DROP:** After dropping a temporary partition, it cannot be recovered using the Recover command.

## TRUNCATE Operations

- **Table TRUNCATE:** Truncating a table removes all temporary partitions, and they cannot be recovered.
- **Regular Partition TRUNCATE:** Truncating a regular partition doesn't affect temporary partitions.
- **Temporary Partition TRUNCATE:** The TRUNCATE command cannot be used on temporary partitions.

## ALTER Operations

- **Schema Changes:** When a table has temporary partitions, you cannot perform Schema Change, Rollup, or other modification operations.
- **Adding Temporary Partitions:** You cannot add temporary partitions to a table that is undergoing modification operations.

# Transaction

---

A transaction is an operation that contains one or more SQL statements. The execution of these statements must either be completely successful or completely fail. It is an indivisible work unit.

## Introduction

Queries and DDL single statements are implicit transactions and are not supported within multi-statement transactions. Each individual write is an implicit transaction by default, and multiple writes can form an explicit transaction. Currently, Doris does not support nested transactions.

## Explicit and Implicit Transactions

### Explicit Transactions

Explicit transactions require users to actively start, commit transactions. Only insert into values statement is supported in 2.1.

```
BEGIN;
[INSERT INTO VALUES]
COMMIT;
```

Rollback is not supported in 2.1.

### Implicit Transactions

Implicit transactions refer to SQL statements that are executed without explicitly adding statements to start and commit transactions before and after the statements.

In Doris, except for [Group Commit](#), each import statement opens a transaction when it starts executing. The transaction is automatically committed after the statement is executed, or automatically rolled back if the statement fails. Each query or DDL statement is also an implicit transaction.

### Isolation Level

The only isolation level currently supported by Doris is READ COMMITTED. Under the READ COMMITTED isolation level, a statement sees only data that was committed before the statement began execution. It does not see uncommitted data.

When a single statement is executed, it captures a snapshot of the tables involved at the start of the statement, meaning that a single statement can only see commits from other transactions made before it began execution. Other transactions' commits are not visible during the execution of a single statement.

When a statement is executed inside a multi-statement transaction:

- It sees only data that was committed before the statement began execution. If another transaction commits between the execution of the first and the second statements, two successive statements in the same transaction may see different data.
- Currently, it cannot see changes made by previous statements within the same transaction.

## No Duplicates, No Loss

Doris supports mechanisms to ensure no duplicates and no loss during data writes. The Label mechanism ensures no duplicates within a single transaction, while two-phase commit coordinates to prevent duplicates across multiple transactions.

## Label Mechanism

Transactions or writes in Doris can be assigned a Label. This Label is typically a user-defined string with some business logic attributes. If not set, a UUID string will be generated internally. The main purpose of a Label is to uniquely identify a transaction or import task and ensure that a transaction or import with the same Label will only execute successfully once. The Label mechanism ensures that data imports are neither lost nor duplicated. If the upstream data source guarantees at-least-once semantics, combined with Doris's Label mechanism, exactly-once semantics can be achieved. Labels are unique within a database.

Doris will clean up Labels based on time and number. By default, if the number of Labels exceeds 2000, cleanup will be triggered. Labels older than three days will also be cleaned up by default. Once a Label is cleaned up, a Label with the same name can execute successfully again, meaning it no longer has deduplication semantics.

Labels are usually set in the format of `business_logic+timestamp`, such as `my_business1_20220330_125000`. This Label typically represents a batch of data generated by the business `my_business1` at 2022-03-30 12:50:00. By setting Labels this way, the business can query the import task status using the Label to clearly determine whether the batch of data at that time has been successfully imported. If not, the import can be retried using the same Label.

## StreamLoad 2PC

[StreamLoad 2PC](#) is mainly used to support exactly-once semantics (EOS) when writing to Doris with Flink.

## Transaction Operations

### Start a Transaction

```
BEGIN;

BEGIN WITH LABEL {user_label};
```

If this statement is executed while the current session is in the middle of a transaction, Doris will ignore the statement, which can also be understood as transactions cannot be nested.

## Commit a Transaction

```
COMMIT;
```

Used to commit all modifications made in the current transaction.

## Transaction with multiple sql statements

Currently, Doris supports only one way of transaction loading.

### Multiple INSERT INTO VALUES for one table

Suppose the table schema is:

```
CREATE TABLE `dt` (
 `id` INT(11) NOT NULL,
 `name` VARCHAR(50) NULL,
 `score` INT(11) NULL
) ENGINE=OLAP
UNIQUE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
 "replication_num" = "1"
);
```

Do transaction load:

```
mysql> BEGIN;
Query OK, 0 rows affected (0.01 sec)
{'label':'txn_insert_b55db21aad7451b-b5b6c339704920c5', 'status':'PREPARE', 'txnId':''}

mysql> INSERT INTO dt (id, name, score) VALUES (1, "Emily", 25), (2, "Benjamin", 35), (3, "Olivia", 28), (4,
"Alexander", 60), (5, "Ava", 17);
Query OK, 5 rows affected (0.08 sec)
{'label':'txn_insert_b55db21aad7451b-b5b6c339704920c5', 'status':'PREPARE', 'txnId':'10013'}

mysql> INSERT INTO dt VALUES (6, "William", 69), (7, "Sophia", 32), (8, "James", 64), (9, "Emma", 37), (10,
"Liam", 64);
Query OK, 5 rows affected (0.00 sec)
{'label':'txn_insert_b55db21aad7451b-b5b6c339704920c5', 'status':'PREPARE', 'txnId':'10013'}

mysql> COMMIT;
Query OK, 0 rows affected (1.02 sec)
{'label':'txn_insert_b55db21aad7451b-b5b6c339704920c5', 'status':'VISIBLE', 'txnId':'10013'}
```

This method not only achieves atomicity, but also in Doris, it enhances the writing performance of INSERT INTO VALUES.

If user enables Group Commit and transaction insert at the same time, the transaction insert will work.

## QA

- Writing to multiple tables must belong to the same Database; otherwise, you will encounter the error Transaction insert must be in the same database

- If the time-consuming from BEGIN statement exceeds the timeout configured in Doris, the transaction will be rolled back. Currently, the timeout uses the maximum value of session variables `insert_timeout` and `query_timeout`.
- When using JDBC to connect to Doris for transaction operations, please add `useLocalSessionState=true` in the JDBC URL; otherwise, you may encounter the error `This is in a transaction, only insert, update, delete, commit, rollback is acceptable`.

## Stream Load 2PC

### 1. Enable two-phase commit by setting `two_phase_commit:true` in the HTTP Header.

```
curl --location-trusted -u user:passwd -H "two_phase_commit:true" -T test.txt
http://fe_host:http_port/api/{db}/{table}/_stream_load
{
 "TxnId": 18036,
 "Label": "55c8ffc9-1c40-4d51-b75e-f2265b3602ef",
 "TwoPhaseCommit": "true",
 "Status": "Success",
 "Message": "OK",
 "NumberTotalRows": 100,
 "NumberLoadedRows": 100,
 "NumberFilteredRows": 0,
 "NumberUnselectedRows": 0,
 "LoadBytes": 1031,
 "LoadTimeMs": 77,
 "BeginTxnTimeMs": 1,
 "StreamLoadPutTimeMs": 1,
 "ReadDataTimeMs": 0,
 "WriteDataTimeMs": 58,
 "CommitAndPublishTimeMs": 0
}
```

### 2. Trigger the commit operation for a transaction (can be sent to FE or BE).

- Specify the transaction using the Transaction ID:

```
curl -X PUT --location-trusted -u user:passwd -H "txn_id:18036" -H "txn_operation:commit"
http://fe_host:http_port/api/{db}/{table}/_stream_load_2pc
{
 "status": "Success",
 "msg": "transaction [18036] commit successfully."
}
```

- Specify the transaction using the label:

```
curl -X PUT --location-trusted -u user:passwd -H "label:55c8ffc9-1c40-4d51-b75e-f2265b3602ef" -H
"txn_operation:commit" http://fe_host:http_port/api/{db}/{table}/_stream_load_2pc
{
 "status": "Success",
 "msg": "label [55c8ffc9-1c40-4d51-b75e-f2265b3602ef] commit successfully."
}
```

### 3. Trigger the abort operation for a transaction (can be sent to FE or BE).

- Specify the transaction using the Transaction ID:

```
curl -X PUT --location-trusted -u user:passwd -H "txn_id:18037" -H "txn_operation:abort"
http://fe_host:http_port/api/{db}/{table}/_stream_load_2pc
{
 "status": "Success",
 "msg": "transaction [18037] abort successfully."
}
```

- Specify the transaction using the label:

```
curl -X PUT --location-trusted -u user:passwd -H "label:55c8ffc9-1c40-4d51-b75e-f2265b3602ef" -H
"txn_operation:abort" http://fe_host:http_port/api/{db}/{table}/_stream_load_2pc
{
 "status": "Success",
 "msg": "label [55c8ffc9-1c40-4d51-b75e-f2265b3602ef] abort successfully."
}
```

## Broker Load into muti tables with a transaction

All Broker Load tasks are atomic and ensure atomicity even when loading multiple tables within the same task. The Label mechanism can be used to ensure data load without loss or duplication.

The following example demonstrates loading data from HDFS by using wildcard patterns to match two sets of files and load them into two different tables.

```
LOAD LABEL example_db.label2
(
 DATA INFILE("hdfs://hdfs_host:hdfs_port/input/file-10*")
 INTO TABLE `my_table1`
 PARTITION (p1)
 COLUMNS TERMINATED BY ","
 (k1, tmp_k2, tmp_k3)
 SET (
 k2 = tmp_k2 + 1,
 k3 = tmp_k3 + 1
)
 DATA INFILE("hdfs://hdfs_host:hdfs_port/input/file-20*")
 INTO TABLE `my_table2`
 COLUMNS TERMINATED BY ","
 (k1, k2, k3)
)
WITH BROKER hdfs
(
 "username"="hdfs_user",
 "password"="hdfs_password"
);
```

The wildcard pattern is used to match and load two sets of files, `file-10*` and `file-20*`, into `my_table1` and `my_table2` respectively. In the case of `my_table1`, the load is specified to the `p1` partition, and the values of thesecond and third columns in the source file are incremented by 1 before being loaded.

# Export Overview

The data export function is used to write the query result set or Doris table data into the specified storage system in the specified file format.

The differences between the export function and the data backup function are as follows:

	Data Export	Data Backup
Final Storage Location	HDFS, Object Storage, Local File System	HDFS, Object Storage
Data Format	Open file formats such as Parquet, ORC, CSV	Doris internal storage format
Execution Speed	Moderate (requires reading data and converting to the target data format)	Fast (no parsing and conversion required, directly upload Doris data files)
Flexibility	Can flexibly define the data to be exported through SQL statements	Only supports table-level full backup
Use Cases	Result set download, data exchange between different systems	Data backup, data migration between Doris clusters

## Choosing Export Methods

Doris provides three different data export methods:

- **SELECT INTO OUTFILE**: Supports the export of any SQL result set.
- **EXPORT**: Supports the export of partial or full table data.
- **MySQL DUMP**: Compatible with the MySQL dump command for data export.

The similarities and differences between the three export methods are as follows:

	SELECT INTO OUTFILE	EXPORT	MySQL DUMP
Synchronous/Asynchronous	Synchronous	Asynchronous (submit EXPORT tasks and check task progress via SHOW EXPORT command)	Synchronous
Supports any SQL	Yes	No	No
Export specific partitions	Yes	Yes	No
Export specific tablets	Yes	No	No
Concurrent export	Supported with high concurrency (depends on whether the SQL statement has operators such as ORDER BY that need to be processed on a single node)	Supported with high concurrency (supports tablet-level concurrent export)	Not supported, single-threaded export only
Supported export data formats	Parquet, ORC, CSV	Parquet, ORC, CSV	MySQL Dump proprietary format

	SELECT INTO OUTFILE	EXPORT	MySQL DUMP
Supports exporting external tables	Yes	Partially supported	No
Supports exporting views	Yes	Yes	Yes
Supported export locations	S3, HDFS	S3, HDFS	LOCAL

## SELECT INTO OUTFILE

Suitable for the following scenarios:

- Data needs to be exported after complex calculations, such as filtering, aggregation, joins, etc.
- Suitable for scenarios that require synchronous tasks.

## EXPORT

Suitable for the following scenarios:

- Large-scale single table export, with simple filtering conditions.
- Scenarios that require asynchronous task submission.

## MySQL Dump

Suitable for the following scenarios:

- Compatible with the MySQL ecosystem, requires exporting both table structure and data.
- Only for development testing or scenarios with very small data volumes.

## Export File Column Type Mapping

Parquet and ORC file formats have their own data types. Doris's export function can automatically map Doris's data types to the corresponding data types in Parquet and ORC file formats. The CSV format does not have types, all data is output as text.

The following table shows the mapping between Doris data types and Parquet, ORC file format data types:

- ORC

Doris Type	Orc Type
boolean	boolean
tinyint	tinyint
smallint	smallint
int	int
bigint	bigint
largeInt	string
date	string

Doris Type	Orc Type
datev2	string
datetime	string
datetimev2	timestamp
float	float
double	double
char / varchar / string	string
decimal	decimal
struct	struct
map	map
array	array
json	string
variant	string
bitmap	binary
quantile_state	binary
hll	binary

- Parquet

When Doris is exported to the Parquet file format, the Doris memory data is first converted to the Arrow memory data format, and then written out to the Parquet file format by Arrow.

Doris Type	Arrow Type	Parquet Physical Type	Parquet Logical Type
boolean	boolean	BOOLEAN	
tinyint	int8	INT32	INT_8
smallint	int16	INT32	INT_16
int	int32	INT32	INT_32
bigint	int64	INT64	INT_64
largeInt	utf8	BYTE_ARRAY	UTF8
date	utf8	BYTE_ARRAY	UTF8
datev2	date32	INT32	DATE
datetime	utf8	BYTE_ARRAY	UTF8
datetimev2	timestamp	INT96/INT64	TIMESTAMP(MICROS/ MILLIS/SECONDS)
float	float32	FLOAT	
double	float64	DOUBLE	
char / varchar / string	utf8	BYTE_ARRAY	UTF8

Doris Type	Arrow Type	Parquet Physical Type	Parquet Logical Type
decimal	decimal128	FIXED_LEN_BYTE_ARRAY	DECIMAL(scale, precision)
struct	struct		Parquet Group
map	map		Parquet Map
array	list		Parquet List
json	utf8	BYTE_ARRAY	UTF8
variant	utf8	BYTE_ARRAY	UTF8
bitmap	binary	BYTE_ARRAY	
quantile_state	binary	BYTE_ARRAY	
hll	binary	BYTE_ARRAY	

Note: In versions 2.1.11 and 3.0.7, you can specify the `parquet.enable_int96_timestamps` property to determine whether Doris's `datetimev2` type uses Parquet's INT96 storage or INT64. INT96 is used by default. However, INT96 has been deprecated in the Parquet standard and is only used for compatibility with some older systems (such as versions before Hive 4.0).

# Export Manual | Export

---

## Export Manual

This document will introduce how to use the EXPORT command to export the data stored in Doris.

Export is a function provided by Doris for asynchronously exporting data. This function can export the data of the tables or partitions specified by users in the specified file format to the target storage systems, including object storage, HDFS or local file system.

Export is an asynchronously executed command. Once the command is executed successfully, it will return the result immediately. Users can view the detailed information of the Export task through the Show Export command.

For the detailed introduction of the EXPORT command, please refer to: [EXPORT](#)

Regarding how to choose between SELECT INTO OUTFILE and EXPORT, please refer to [Export Overview](#).

## Applicable Scenarios

Export is applicable to the following scenarios:

- Exporting a single table with a large amount of data, only requiring simple filtering conditions.
- Scenarios where tasks need to be submitted asynchronously.

The following limitations should be noted when using Export:

- Currently, exporting in compressed text file formats is not supported.
- Exporting the result set of Select is not supported. If you need to export the Select result set, please use [OUTFILE Export](#).

## Quick Start

### Table Creation and Data Import

```
CREATE TABLE IF NOT EXISTS tbl (
 `c1` int(11) NULL,
 `c2` string NULL,
 `c3` bigint NULL
)
DISTRIBUTED BY HASH(c1) BUCKETS 20
PROPERTIES("replication_num" = "1");

insert into tbl values
 (1, 'doris', 18),
 (2, 'nereids', 20),
 (3, 'pipelibe', 99999),
 (4, 'Apache', 122123455),
 (5, null, null);
```

## Create an Export Job

### Export to HDFS

Export all data from the `tbl` table to HDFS. Set the file format of the export job to csv (the default format) and set the column delimiter to `,`.

```
EXPORT TABLE tbl
TO "hdfs://host/path/to/export/"
PROPERTIES
(
 "line_delimiter" = ",",
)
with HDFS (
 "fs.defaultFS"="hdfs://hdfs_host:port",
 "hadoop.username" = "hadoop"
);
```

### Export to Object Storage

Export all the data in the `tbl` table to the object storage, set the file format of the export job to csv (the default format), and set the column delimiter to `,`.

```
EXPORT TABLE tbl TO "s3://bucket/export/export_"
PROPERTIES (
 "line_delimiter" = ",",
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);
```

## View Export Jobs

After submitting a job, you can query the status of the export job via the [SHOW EXPORT](#) command. An example of the result is as follows:

```
mysql> show export\G
***** 1. row *****
 JobId: 143265
 Label: export_0aa6c944-5a09-4d0b-80e1-cb09ea223f65
 State: FINISHED
 Progress: 100%
 TaskInfo: {"partitions":
[{"parallelism":5,"data_consistency":"partition","format":"csv","broker":"S3","column_separator":"\t","line_delimiter":"\n","max_file_size":"2048MB","delete_existing_files":"","with_bom":"false","db":"tpch1","tbl":"lineitem"}]
 Path: s3://bucket/export/export_
 CreateTime: 2024-06-11 18:01:18
 StartTime: 2024-06-11 18:01:18
 FinishTime: 2024-06-11 18:01:31
 Timeout: 7200
 ErrorMsg: NULL
 OutfileInfo: [
```

```
[
 {
 "fileNumber": "1",
 "totalRows": "6001215",
 "fileSize": "747503989",
 "url": "s3://bucket/export/export_6555cd33e7447c1-baa9568b5c4eb0ac_*"
 }
]
1 row in set (0.00 sec)
```

For the detailed usage of the `show export` command and the meaning of each column in the returned results, please refer to [SHOW EXPORT](#).

## Cancel Export Jobs

After submitting an Export job, the export job can be cancelled via the [CANCEL EXPORT](#) command before the Export task succeeds or fails. An example of the cancellation command is as follows:

```
CANCEL EXPORT FROM dbName WHERE LABEL like "%export_%";
```

## Export Instructions

### Export Data Sources

EXPORT currently supports exporting the following types of tables or views:

- Internal tables in Doris
- Logical views in Doris
- Tables in External Catalog

### Export Data Storage Locations

Export currently supports exporting to the following storage locations:

- Object storage: Amazon S3, COS, OSS, OBS, Google GCS
- HDFS

### Export File Types

EXPORT currently supports exporting to the following file formats:

- Parquet
- ORC
- csv
- csv\_with\_names
- csv\_with\_names\_and\_types

## Examples

### Export to an HDFS Cluster with High Availability Enabled

If the HDFS has high availability enabled, HA information needs to be provided. For example:

```
EXPORT TABLE tbl
TO "hdfs://HDFS8000871/path/to/export_"
PROPERTIES
(
 "line_delimiter" = ",",
)
with HDFS (
 "fs.defaultFS" = "hdfs://HDFS8000871",
 "hadoop.username" = "hadoop",
 "dfs.nameservices" = "your-nameservices",
 "dfs.ha.namenodes.your-nameservices" = "nn1,nn2",
 "dfs.namenode.rpc-address.HDFS8000871.nn1" = "ip:port",
 "dfs.namenode.rpc-address.HDFS8000871.nn2" = "ip:port",
 "dfs.client.failover.proxy.provider.HDFS8000871" =
"org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
);
```

### Export to an HDFS Cluster with High Availability and Kerberos Authentication Enabled

If the HDFS cluster has both high availability enabled and Kerberos authentication enabled, you can refer to the following SQL statements:

```
EXPORT TABLE tbl
TO "hdfs://HDFS8000871/path/to/export_"
PROPERTIES
(
 "line_delimiter" = ",",
)
with HDFS (
 "fs.defaultFS"="hdfs://hacluster/",
 "hadoop.username" = "hadoop",
 "dfs.nameservices"="hacluster",
 "dfs.ha.namenodes.hacluster"="n1,n2",
 "dfs.namenode.rpc-address.hacluster.n1"="192.168.0.1:8020",
 "dfs.namenode.rpc-address.hacluster.n2"="192.168.0.2:8020",

 "dfs.client.failover.proxy.provider.hacluster"="org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverP
roxyProvider",
 "dfs.namenode.kerberos.principal"="hadoop/_HOST@REALM.COM",
 "hadoop.security.authentication"="kerberos",
 "hadoop.kerberos.principal"="doris_test@REALM.COM",
 "hadoop.kerberos.keytab"="/path/to/doris_test.keytab"
);
```

### Specify Partition for Export

The export job supports exporting only some partitions of the internal tables in Doris. For example, only export partitions p1 and p2 of the test table.

```
EXPORT TABLE test
PARTITION (p1,p2)
TO "s3://bucket/export/export_"
PROPERTIES (
 "columns" = "k1,k2"
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);
```

## Filter Data During Export

The export job supports filtering data according to predicate conditions during the export process, exporting only the data that meets the conditions. For example, only export the data that satisfies the condition `k1 < 50`.

```
EXPORT TABLE test
WHERE k1 < 50
TO "s3://bucket/export/export_"
PROPERTIES (
 "columns" = "k1,k2",
 "column_separator"=", "
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);
```

## Export External Table Data

The export job supports the data of tables in External Catalog.

```
-- Create a hive catalog
CREATE CATALOG hive_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://172.0.0.1:9083'
);

-- Export hive table
EXPORT TABLE hive_catalog.sf1.lineitem TO "s3://bucket/export/export_"
PROPERTIES(
 "format" = "csv",
 "max_file_size" = "1024MB"
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);
```

## Clearing the Export Directory Before Exporting

```
EXPORT TABLE test TO "s3://bucket/export/export_"
PROPERTIES (
```

```

 "format" = "parquet",
 "max_file_size" = "512MB",
 "delete_existing_files" = "true"
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);

```

If "delete\_existing\_files" = "true" is set, the export job will first delete all files and directories under the s3://bucket/export/ directory, and then export the data to this directory.

If you want to use the delete\_existing\_files parameter, you also need to add the configuration enable\_delete\_existing\_files = true in the fe.conf and restart the FE. Only then will the delete\_existing\_files take effect. This operation will delete the data of the external system and is a high-risk operation. Please ensure the permissions and data security of the external system on your own.

## Setting the Size of Exported Files

The export job supports setting the size of the export file. If the size of a single file exceeds the set value, it will be divided into multiple files for export according to the specified size.

```

EXPORT TABLE test TO "s3://bucket/export/export_"
PROPERTIES (
 "format" = "parquet",
 "max_file_size" = "512MB"
) WITH s3 (
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);

```

By setting "max\_file\_size" = "512MB", the maximum size of a single exported file is 512MB.

max\_file\_size cannot be less than 5MB and cannot be greater than 2GB.

In versions 2.1.11 and 3.0.7, the maximum limit of 2GB was removed, leaving only the minimum limit of 5MB.

## Notice

- Export Data Volume

It is not recommended to export a large amount of data at one time. The recommended maximum export data volume for an Export job is several tens of gigabytes. Excessive exports will lead to more junk files and higher retry costs. If the table data volume is too large, it is recommended to export by partitions.

In addition, the Export job will scan data and occupy IO resources, which may affect the query latency of the system.

- Export File Management

If the Export job fails, the files that have already been generated will not be deleted, and users need to delete them manually.

- Export Timeout

If the amount of exported data is very large and exceeds the export timeout period, the Export task will fail. At this time, you can specify the `timeout` parameter in the Export command to increase the timeout period and retry the Export command.

- Export Failure

During the operation of the Export job, if the FE restarts or switches the master, the Export job will fail, and the user needs to resubmit it. You can check the status of the Export task through the `show export` command.

- Number of Exported Partitions

The maximum number of partitions allowed to be exported by an Export Job is 2000. You can add the parameter `maximum_number_of_export_partitions` in `fe.conf` and restart the FE to modify this setting.

- Data Integrity

After the export operation is completed, it is recommended to verify whether the exported data is complete and correct to ensure the quality and integrity of the data.

## Appendix

### Basic Principle

The underlying layer of the Export task is to execute the `SELECT INTO OUTFILE` SQL statement. After a user initiates an Export task, Doris will construct one or more `SELECT INTO OUTFILE` execution plans according to the table to be exported by Export, and then submit these `SELECT INTO OUTFILE` execution plans to the Job Schedule task scheduler of Doris. The Job Schedule task scheduler will automatically schedule and execute these tasks.

### Exporting to the Local File System

The function of exporting to the local file system is disabled by default. This function is only used for local debugging and development, and should not be used in the production environment.

If you want to enable this function, please add `enable_outfile_to_local=true` in the `fe.conf` and restart the FE.

Example: Export all the data in the `tbl` table to the local file system, set the file format of the export job to csv (the default format), and set the column delimiter to `,`.

```
EXPORT TABLE tbl TO "file:///path/to/result_"
PROPERTIES (
 "format" = "csv",
 "line_delimiter" = ",",
);
```

This function will export and write data to the disk of the node where the BE is located. If there are multiple BE nodes, the data will be scattered on different BE nodes according to the concurrency of the export task, and each node will have a part of the data.

As in this example, a set of files similar to `result_7052bac522d840f5-972079771289e392_0.csv` will eventually be produced under `/path/to/` of the BE node.

The specific BE node IP can be viewed in the `OutfileInfo` column in the `SHOW EXPORT` result, such as:

```
[
 [
 {
 "fileNumber": "1",
 "totalRows": "0",
 "fileSize": "8388608",
 "url": "file:///172.20.32.136/path/to/result_7052bac522d840f5-972079771289e392_*"
 }
],
 [
 {
 "fileNumber": "1",
 "totalRows": "0",
 "fileSize": "8388608",
 "url": "file:///172.20.32.137/path/to/result_22aba7ec933b4922-ba81e5eca12bf0c2_*"
 }
]
]
```

**This function is not applicable to the production environment, and please ensure the permissions of the export directory and data security on your own.**

# SELECT INTO OUTFILE

---

This document will introduce how to use the `SELECT INTO OUTFILE` command to perform the export operation of query results.

The `SELECT INTO OUTFILE` command exports the result data of the `SELECT` part to the target storage system in the specified file format, including object storage or HDFS.

The `SELECT INTO OUTFILE` is a synchronous command, the return of the command means the export is finished. If the export is successful, information such as the number, size, and path of the exported files will be returned. If the export fails, error information will be returned.

Regarding how to choose between `SELECT INTO OUTFILE` and `EXPORT`, please refer to [Export Overview](#).

For a detailed introduction to the `SELECT INTO OUTFILE` command, please refer to: [SELECT INTO OUTFILE](#)

## Applicable Scenarios

The `SELECT INTO OUTFILE` is applicable to the following scenarios:

- When the exported data needs to go through complex calculation logic, such as filtering, aggregation, joining, etc.
- It is suitable for scenarios where synchronous tasks need to be executed.

The following limitations should be noted when using the `SELECT INTO OUTFILE`:

- Compression formats for text is not supported.
- The pipeline engine in version 2.1 does not support concurrent exports.

## Quick Start

### Creating Tables and Importing Data

```
CREATE TABLE IF NOT EXISTS tbl (
 `c1` int(11) NULL,
 `c2` string NULL,
 `c3` bigint NULL
)
DISTRIBUTED BY HASH(c1) BUCKETS 20
PROPERTIES("replication_num" = "1");

insert into tbl values
 (1, 'doris', 18),
 (2, 'nereids', 20),
 (3, 'pipelibe', 99999),
 (4, 'Apache', 122123455),
 (5, null, null);
```

## Export to HDFS

Export the query results to the directory `hdfs://path/to/` and specify the export format as Parquet:

```
SELECT c1, c2, c3 FROM tbl
INTO OUTFILE "hdfs://ip:port/path/to/result_"
FORMAT AS PARQUET
PROPERTIES
(
 "fs.defaultFS" = "hdfs://ip:port",
 "hadoop.username" = "hadoop"
);
```

## Export to Object Storage

Export the query results to the `s3://bucket/export/` directory in the s3 storage, specify the export format as ORC, and information such as sk (secret key) and ak (access key) needs to be provided.

```
SELECT * FROM tbl
INTO OUTFILE "s3://bucket/export/result_"
FORMAT AS ORC
PROPERTIES(
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx"
);
```

## Export Instructions

### Export Destination

The `SELECT INTO OUTFILE` currently supports exporting to the following storage locations:

- Object Storage: Amazon S3, COS, OSS, OBS, Google GCS
- HDFS

### Supported File Types

The `SELECT INTO OUTFILE` currently supports exporting the following file formats:

- Parquet
- ORC
- csv
- csv\_with\_names
- csv\_with\_names\_and\_types

### Export concurrency

You can enable concurrent export through the session variable `enable_parallel_outfile`.

```
SET enable_parallel_outfile=true;
```

Concurrent export will use multi-node and multi-thread to export result data to improve the overall export throughout. However, concurrent export may generate more files.

Note that some queries cannot perform concurrent export even if this variable is turned on, such as queries containing global sorting. If the number of rows returned by the export command is greater than 1, it means that concurrent export is enabled.

## Export Examples

### Export to an HDFS Cluster with High Availability Enabled

If HDFS has high availability enabled, HA (High Availability) information needs to be provided, such as:

```
SELECT c1, c2, c3 FROM tbl
INTO OUTFILE "hdfs://HDFS8000871/path/to/result_"
FORMAT AS PARQUET
PROPERTIES
(
 "fs.defaultFS" = "hdfs://HDFS8000871",
 "hadoop.username" = "hadoop",
 "dfs.nameservices" = "your-nameservices",
 "dfs.ha.namenodes.your-nameservices" = "nn1,nn2",
 "dfs.namenode.rpc-address.HDFS8000871.nn1" = "ip:port",
 "dfs.namenode.rpc-address.HDFS8000871.nn2" = "ip:port",
 "dfs.client.failover.proxy.provider.HDFS8000871" =
 "org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider"
);
```

### Export to an HDFS Cluster with High Availability and Kerberos Authentication Enabled

If the HDFS cluster has high availability enabled and Kerberos authentication is enabled, you can refer to the following SQL statement:

```
SELECT * FROM tbl
INTO OUTFILE "hdfs://path/to/result_"
FORMAT AS PARQUET
PROPERTIES
(
 "fs.defaultFS"="hdfs://hacluster/",
 "hadoop.username" = "hadoop",
 "dfs.nameservices"="hacluster",
 "dfs.ha.namenodes.hacluster"="n1,n2",
 "dfs.namenode.rpc-address.hacluster.n1"="192.168.0.1:8020",
 "dfs.namenode.rpc-address.hacluster.n2"="192.168.0.2:8020",

 "dfs.client.failover.proxy.provider.hacluster"="org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider",
 "dfs.namenode.kerberos.principal"="hadoop/_HOST@REALM.COM",
 "hadoop.security.authentication"="kerberos",
 "hadoop.kerberos.principal"="doris_test@REALM.COM",
 "hadoop.kerberos.keytab"="/path/to/doris_test.keytab"
);
```

## Generating an Export Success Indicator File

The `SELECT INTO OUTFILE` command is a synchronous command. Therefore, it is possible that the task connection is disconnected during the execution of the SQL, making it impossible to know whether the exported data has ended normally or is complete. At this time, you can use the `success_file_name` parameter to require that a file indicator be generated in the directory after a successful export.

Similar to Hive, users can judge whether the export has ended normally and whether the files in the export directory are complete by checking whether there is a file specified by the `success_file_name` parameter in the export directory.

For example: Export the query results of the select statement to the object storage: `s3://bucket/export/`. Specify the export format as `csv`. Specify the name of the export success indicator file as `SUCCESS`. After the export is completed, a indicator file will be generated.

```
SELECT k1,k2,v1 FROM tbl1 LIMIT 100000
INTO OUTFILE "s3://bucket/export/result_"
FORMAT AS CSV
PROPERTIES
(
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx",
 "column_separator" = ",",
 "line_delimiter" = "\n",
 "success_file_name" = "SUCCESS"
);
```

After the export is completed, one more file will be written, and the file name of this file is `SUCCESS`.

## Clearing the Export Directory Before Exporting

```
SELECT * FROM tbl1
INTO OUTFILE "s3://bucket/export/result_"
FORMAT AS CSV
PROPERTIES
(
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx",
 "column_separator" = ",",
 "line_delimiter" = "\n",
 "delete_existing_files" = "true"
);
```

If `"delete_existing_files" = "true"` is set, the export job will first delete all files and directories under the `s3://bucket/export/` directory, and then export the data to this directory.

If you want to use the `delete_existing_files` parameter, you also need to add the configuration `enable_delete_existing_files = true` in `fe.conf` and restart the FE. Only then will the `delete_existing_files` parameter take effect. This operation will delete the data of the external system,

which is a high-risk operation. Please ensure the permissions and data security of the external system on your own.

## Setting the Size of Exported Files

```
SELECT * FROM tbl
INTO OUTFILE "s3://path/to/result_"
FORMAT AS ORC
PROPERTIES(
 "s3.endpoint" = "xxxxx",
 "s3.region" = "xxxxx",
 "s3.secret_key"="xxxx",
 "s3.access_key" = "xxxxx",
 "max_file_size" = "2048MB"
);
```

Since "max\_file\_size" = "2048MB" is specified, if the final generated file is not larger than 2GB, there will be only one file. If it is larger than 2GB, there will be multiple files.

## Notice

### 1. Export Data Volume and Export Efficiency

The SELECT INTO OUTFILE function is essentially executing an SQL query command. If concurrent exports are not enabled, the query results are exported by a single BE node in a single thread.

Therefore, the entire export time includes the time consumed by the query itself and the time consumed by writing out the final result set. Enabling concurrent exports can reduce the export time.

### 2. Export Timeout

The timeout period of the export command is the same as that of the query. If the export data times out due to a large amount of data, you can set the session variable query\_timeout to appropriately extend the query timeout period.

### 3. Management of Exported Files

Doris does not manage the exported files. Whether the files are successfully exported or left over after a failed export, users need to handle them on their own.

In addition, the SELECT INTO OUTFILE command does not check whether files or file paths exist.

Whether the SELECT INTO OUTFILE command will automatically create paths or overwrite existing files is completely determined by the semantics of the remote storage system.

### 4. If the Query Result Set Is Empty

For an export with an empty result set, an empty file will still be generated.

### 5. File Splitting

File splitting ensures that a row of data is completely stored in a single file. Therefore, the size of the file is not strictly equal to max\_file\_size.

### 6. Functions with Non-visible Characters

For some functions whose output is non-visible characters, such as BITMAP and HLL types, when exported to the CSV file format, the output is \N.

## Appendix

### Export to Local File System

The function of exporting to the local file system is turned off by default. This function is only used for local debugging and development, and should not be used in the production environment.

If you want to enable this function, please add `enable_outfile_to_local=true` in `fe.conf` and restart the FE.

Example: Export all the data in the `tbl` table to the local file system, set the file format of the export job to `csv` (the default format), and set the column separator to `,`.

```
SELECT c1, c2 FROM db.tbl
INTO OUTFILE "file:///path/to/result_"
FORMAT AS CSV
PROPERTIES(
 "column_separator" = ",",
);
```

This function will export and write data to the disk of the node where the BE is located. If there are multiple BE nodes, the data will be scattered on different BE nodes according to the concurrency of the export task, and each node will have a part of the data.

As in this example, a set of files similar to `result_c6df5f01bd664dde-a2168b019b6c2b3f_0.csv` will eventually be produced under `/path/to/` of the BE node.

The specific BE node IP will be displayed in the returned results, such as:

```
+-----+-----+-----+-----+
--+
| FileNumber | TotalRows | FileSize | URL
|
+-----+-----+-----+-----+
--+
| 1 | 1195072 | 4780288 | file:///172.20.32.136/path/to/result_c6df5f01bd664dde-
a2168b019b6c2b3f_* |
| 1 | 1202944 | 4811776 | file:///172.20.32.136/path/to/result_c6df5f01bd664dde-
a2168b019b6c2b40_* |
| 1 | 1198880 | 4795520 | file:///172.20.32.137/path/to/result_c6df5f01bd664dde-
a2168b019b6c2b43_* |
| 1 | 1198880 | 4795520 | file:///172.20.32.137/path/to/result_c6df5f01bd664dde-
a2168b019b6c2b45_* |
+-----+-----+-----+-----+
--+
```

**This function is not suitable for the production environment, and please ensure the permissions and data security of the export directory on your own.**

# Using MySQL Dump

---

Doris has supported exporting data or table structures through the `mysqldump` tool after version 0.15

## Examples

### Export

1. Export the table1 table in the test database: `mysqldump -h127.0.0.1 -P9030 -uroot --no-tablespaces --databases test --tables table1`
2. Export the table1 table structure in the test database: `mysqldump -h127.0.0.1 -P9030 -uroot --no-tablespaces --databases test --tables table1 --no-data`
3. Export all tables in the test1, test2 database: `mysqldump -h127.0.0.1 -P9030 -uroot --no-tablespaces --databases test1 test2`
4. Export all databases and tables `mysqldump -h127.0.0.1 -P9030 -uroot --no-tablespaces --all-databases` For more usage parameters, please refer to the manual of `mysqldump`

### Import

The results exported by `mysqldump` can be redirected to a file, which can then be imported into Doris through the source command `source filename.sql`

## Notice

1. Since there is no concept of tablespace in mysql in Doris, add the `--no-tablespaces` parameter when using `mysqldump`
2. Using `mysqldump` to export data and table structure is only used for development and testing or when the amount of data is small. Do not use it in a production environment with a large amount of data.

# Best Practices | Export

---

## Best Practices

This document mainly introduces how to determine whether resource utilization is reasonable during data export operations, and how to adjust resource utilization to achieve better data export efficiency.

### SELECT INTO OUTFILE

#### 1. Enable parallel export

The number of rows returned by `SELECT INTO OUTFILE` represents the number of parallel Writers. The more Writers, the higher the export concurrency, but the number of output files will also increase. If you find there is only one Writer, you can try enabling the parallel export feature.

```
SET enable_parallel_outfile=true
```

After enabling, the `SELECT INTO OUTFILE` operation generates the corresponding number of Writers based on the query's parallelism. The query parallelism is controlled by the session variable `parallel_pipeline_task_num`. By default, it's half of the number of CPU cores per BE.

For example, in a cluster with 3 BE nodes, where each node has 8 CPU cores. When parallel export is enabled, it will generate  $(4 \times 3 =)$  12 Writers.

Note that even if `enable_parallel_outfile` is enabled, not all queries can be exported in parallel. For example, if the query contains global sorting and aggregation semantics, it cannot be exported in parallel. For example:

```
SELECT * FROM table ORDER BY id;

SELECT SUM(cost) FROM table;
```

#### 2. Determine export speed

Each row result returned by `SELECT INTO OUTFILE` contains the time (in seconds) and speed (in KB/s) of the corresponding Writer's output.

Adding up the speeds of multiple Writers on the same node gives you the write speed of a single node. You can compare this speed with disk bandwidth (e.g., when exporting to local) or network bandwidth (e.g., when exporting to object storage) to see if it has reached the bandwidth bottleneck.

## Export

#### 1. Determine export execution status from the return results

The Export command essentially breaks down the task into multiple `SELECT INTO OUTFILE` clauses for execution.

The results returned by the `SHOW EXPORT` command contain a JSON string, which is a two-dimensional array. The first dimension represents the number of concurrent threads in Export, with the number of concurrent threads representing how many Outfile statements were initiated concurrently. The second dimension represents the return results of a single Outfile statement. Example:

```
[
 [
 {
 "fileNumber": "1",
 "totalRows": "640321",
 "fileSize": "350758307",
 "url": "file:///127.0.0.1/mnt/disk2/ftw/tmp/export/exp_59fd917c43874adc-9b1c3e9cd6e655be_*",
 "writeTime": "17.989",
 "writeSpeed": "19041.66"
 },
 {...},
 {...},
 {...}
],
 [
 {
 "fileNumber": "1",
 "totalRows": "646609",
 "fileSize": "354228704",
 "url": "file:///127.0.0.1/mnt/disk2/ftw/tmp/export/exp_c75b9d4b59bf4943-92eb94a7b97e46cb_*",
 "writeTime": "17.249",
 "writeSpeed": "20054.64"
 },
 {...},
 {...},
 {...}
]
]
```

In the above example, 2 Outfile commands were initiated. Each command has 4 Writers writing concurrently.

By adjusting the `parallelism` parameter in the Export command properties, you can control the number of concurrent Outfile operations, thereby controlling the concurrency level.

## 2. Parameters affecting parallelism

The parallelism of Export jobs depends on two parameters:

- `parallelism`

Used to set the maximum number of Outfile commands to split into.

- `data_consistency`

Whether to split Outfile commands within partitions. This parameter defaults to `partition`, which means no further splitting within partitions. That is, the number of Outfile commands will only be less than or equal to the number of partitions involved. If set to `none`, a partition will be further split, which can improve concurrency, but if the partition is being written to, it may sacrifice export

consistency (i.e., different Outfile commands for the same partition may export different versions of data from that partition).

For details, please refer to [Export Command Manual](#)

- `async_task_consumer_thread_num`

This is an FE configuration parameter that indicates the number of Export Tasks that the current cluster can run concurrently. The default value is 64. An Export Job is split into multiple Export Tasks based on concurrency. All Export Tasks share this threshold. To increase the overall number of concurrent export tasks that the cluster can execute, increase this parameter and restart the FE node.

# MySQL Compatibility

Doris is highly compatible with MySQL syntax and supports standard SQL. However, there are several differences between Doris and MySQL, as outlined below.

## Data Types

### Numeric Types

Type	MySQL	Doris
Boolean		
Bit		Not supported
Tinyint		
Smallint		
Mediumint		- Not supported
Int		
Bigint		
Largeint	- Not supported	
Decimal		
Float/Double		

### Date Types

Type	MySQL	Doris
Date		
Date Time		
Timestamp		- Not supported
Time		- Not supported
Year		- Not supported

### String Types

Type	MySQL	Doris
Char		

Type	MySQL	Doris
Varchar		
String	- Not supported	
Binary		- Not supported
Varbinary		
Blob		- Not supported
Text		- Not supported
Enum		- Not supported
Set		- Not supported

## JSON Type

Type	MySQL	Doris
JSON	Supported	Supported

## Doris unique data type

Doris has several unique data types. Here are the details:

- **HyperLogLog**

HLL (HyperLogLog) is a data type that cannot be used as a key column. In an aggregate model table, the corresponding aggregation type for HLL is HLL\_UNION. The length and default value do not need to be specified. The length is controlled internally based on the data aggregation level. HLL columns can only be queried or used with HLL\_UNION\_AGG, HLL\_RAW\_AGG, HLL\_CARDINALITY, HLL\_HASH, and other related functions.

HLL is used for approximate fuzzy deduplication and performs better than count distinct when dealing with large amounts of data. The typical error rate of HLL is around 1%, sometimes reaching up to 2%.

- **Bitmap**

Bitmap is a data type that cannot be used as a key column. In aggregate model table, the corresponding aggregation type for BITMAP is BITMAP\_UNION. Similar to HLL, the length and default values do not need to be specified, and the length is controlled internally based on the data aggregation level. Bitmap columns can only be queried or used with functions like BITMAP\_UNION\_COUNT, BITMAP\_UNION, BITMAP\_HASH, BITMAP\_HASH64 and others.

Using BITMAP in traditional scenarios may impact loading speed, but it generally performs better than Count Distinct when dealing with large amounts of data. Please note that in real-time scenarios, using BITMAP without a global dictionary and with bitmap\_hash() function may introduce an error of around 0.1%. If this error is not acceptable, you can use bitmap\_hash64 instead.

- **QUANTILE\_PERCENT**

QUANTILE\_STATE is a data type that cannot be used as a key column. In an aggregate model table, the corresponding aggregation type for QUANTILE\_STATE is QUANTILE\_UNION. The length and default value do not need to be specified, and the length is controlled internally based on the data aggregation level. QUANTILE\_STATE columns can only be queried or used with functions like QUANTILE\_PERCENT, QUANTILE\_UNION, TO\_QUANTILE\_STATE and others.

QUANTILE\_STATE is used for calculating approximate quantile values. During import, it performs pre-aggregation on the same key with different values. When the number of values does not exceed 2048, it stores all the data in detail. When the number of values exceeds 2048, it uses the TDigest algorithm to aggregate (cluster) the data and save the centroids of the clusters.

- **Array<T>**

Array is a data type in Doris that represents an array composed of elements of type T. It cannot be used as a key column.

- **MAP<K, V>**

MAP is a data type in Doris that represents a map composed of elements of types K and V.

- **STRUCT<field\_name:field\_type,...>**

A structure (STRUCT) is composed of multiple fields. It can also be identified as a collection of multiple columns.

- field\_name: The identifier of the field, which must be unique.
- field\_type: The type of field.

- **Agg\_State**

AGG\_STATE is a data type in Doris that cannot be used as a key column. During table creation, the signature of the aggregation function needs to be declared.

The length and default value do not need to be specified, and the actual storage size depends on the implementation of the function.

AGG\_STATE can only be used in combination with [STATE](#) / [MERGE](#) / [UNION](#) functions from the SQL manual for aggregators.

## Syntax

### DDL

#### 01 Create Table Syntax in Doris

```
CREATE TABLE [IF NOT EXISTS] [database.]table
(
 column_definition_list
 [, index_definition_list]
)
```

```
[engine_type]
[keys_type]
[table_comment]
[partition_info]
distribution_desc
[rollup_list]
[properties]
[extra_properties]
```

## 02 Differences with MySQL

Parameter	Differences from MySQL
Column_definition_list	<ul style="list-style-type: none"> <li>- Field list definition: The basic syntax is similar to MySQL but includes an additional operation for aggregate types.</li> <li>- The aggregate type operation primarily supports Aggregate.</li> <li>- When creating a table, MySQL allows adding constraints like Index (e.g., Primary Key, Unique Key) after the field list definition, while Doris supports these constraints and computations by defining data models.</li> </ul>
Index_definition_list	<ul style="list-style-type: none"> <li>- Index list definition: The basic syntax is similar to MySQL, supporting bitmap indexes, inverted indexes, and N-Gram indexes, but Bloom filter indexes are set through properties.</li> <li>- MySQL supports B+Tree and Hash indexes.</li> </ul>
Engine_type	<ul style="list-style-type: none"> <li>- Table engine type: Optional.</li> <li>- The currently supported table engine is mainly the OLAP native engine.</li> <li>- MySQL supports storage engines such as Innodb, MyISAM, etc.</li> </ul>
Keys_type	<ul style="list-style-type: none"> <li>- Data model: Optional.</li> <li>- Supported types include: 1) DUPLICATE KEY (default): The specified columns are sort columns. 2) AGGREGATE KEY: The specified columns are dimension columns. 3) UNIQUE KEY: The specified columns are primary key columns.</li> <li>- MySQL does not have the concept of a data model.</li> </ul>
Table_comment	Table comment
Partition_info	<ul style="list-style-type: none"> <li>- Partitioning algorithm: Optional. Doris supported partitioning algorithms include:</li> <li>- LESS THAN: Only defines the upper bound of partitions. The lower bound is determined by the upper bound of the previous partition.</li> <li>- FIXED RANGE: Defines left-closed and right-open intervals for partitions.</li> <li>- MULTI RANGE: Creates multiple RANGE partitions in bulk, defining left-closed and right-open intervals, setting time units and steps. Time units support years, months, days, weeks, and hours. MySQL supports algorithms such as Hash, Range, List, Key. MySQL also supports subpartitions, with only Hash and Key supported for subpartitions.</li> </ul>
Distribution_desc	<ul style="list-style-type: none"> <li>- Bucketing algorithm: Required. Includes: 1) Hash bucketing syntax: DISTRIBUTED BY HASH (k1[,k2 ...]) [BUCKETS num auto]. Description: Uses specified key columns for hash bucketing. 2) Random bucketing syntax: DISTRIBUTED BY RANDOM [BUCKETS num auto]. Description: Uses random numbers for bucketing.</li> <li>- MySQL does not have a bucketing algorithm.</li> </ul>
Rollup_list	<ul style="list-style-type: none"> <li>- Multiple sync materialized views can be created while creating the table.</li> <li>- Syntax: rollup_name (col1[, col2, ...]) [DUPLICATE KEY(col1[, col2, ...])] [PROPERTIES("key" = "value")]</li> <li>- MySQL does not support this.</li> </ul>
Properties	Table properties: They differ from MySQL's table properties, and the syntax for defining table properties also differs from MySQL.

## 03 CREATE INDEX

```
CREATE INDEX [IF NOT EXISTS] index_name ON table_name (column [, ...],) [USING BITMAP];
```

- Doris currently supports Bitmap index, Inverted index, and N-Gram index. BloomFilter index are supported as well, but they have a separate syntax for setting them.
- MySQL supports index algorithms such as B+Tree and Hash.

## 04 CREATE VIEW

```
CREATE VIEW [IF NOT EXISTS]
[db_name.]view_name
(column1[COMMENT "col comment"][, column2, ...])
AS query_stmt

CREATE MATERIALIZED VIEW (IF NOT EXISTS)? mvName=multipartIdentifier
(LEFT_PAREN cols=simpleColumnDefs RIGHT_PAREN)? buildMode?
(REFRESH refreshMethod? refreshTrigger?)?
(KEY keys=identifierList)?
(COMMENT STRING_LITERAL)?
(PARTITION BY LEFT_PAREN partitionKey = identifier RIGHT_PAREN)?
(DISTRIBUTED BY (HASH hashKeys=identifierList | RANDOM) (BUCKETS (INTEGER_VALUE | AUTO))?)?
propertyClause?
AS query
```

- The basic syntax is consistent with MySQL.
- Doris supports logical view and supports two types of materialized views: synchronous materialized views and asynchronous materialized views
- MySQL do not supports asynchronous materialized views.

## 05 ALTER TABLE / ALTER INDEX

The syntax of Doris ALTER is basically the same as that of MySQL.

## DROP TABLE / DROP INDEX

The syntax of Doris DROP is basically the same as MySQL.

## DML

### INSERT

```
INSERT INTO table_name
[PARTITION (p1, ...)]
[WITH LABEL label]
[(column [, ...])]
[[hint [, ...]]]
{ VALUES ({ expression | DEFAULT } [, ...]) [, ...] | query }
```

The Doris INSERT syntax is basically the same as MySQL.

## UPDATE

```
UPDATE target_table [table_alias]
 SET assignment_list
 WHERE condition

assignment_list:
 assignment [, assignment] ...

assignment:
 col_name = value

value:
 {expr | DEFAULT}
```

The Doris UPDATE syntax is basically the same as MySQL, but it should be noted that the WHERE **condition must be added**.

## Delete

```
DELETE FROM table_name [table_alias]
 [PARTITION partition_name | PARTITIONS (partition_name [, partition_name])]
 WHERE column_name op { value | value_list } [AND column_name op { value | value_list } ...];
```

The syntax can only specify filter predicates

```
DELETE FROM table_name [table_alias]
 [PARTITION partition_name | PARTITIONS (partition_name [, partition_name])]
 [USING additional_tables]
 WHERE condition
```

This syntax can only be used on the UNIQUE KEY model table.

The DELETE syntax in Doris is basically the same as in MySQL. However, since Doris is an analytical database, deletions cannot be too frequent.

## SELECT

```
SELECT
 [hint_statement, ...]
 [ALL | DISTINCT]
 select_expr [, select_expr ...]
 [EXCEPT (col_name1 [, col_name2, col_name3, ...])]
 [FROM table_references
 [PARTITION partition_list]
 [TABLET tabletid_list]
 [TABLESAMPLE sample_value [ROWS | PERCENT]
 [REPEATABLE pos_seek]]
 [WHERE where_condition]
 [GROUP BY [GROUPING SETS | ROLLUP | CUBE] {col_name | expr | position}]
 [HAVING where_condition]
```

```
[ORDER BY {col_name | expr | position} [ASC | DESC], ...]
[LIMIT {[offset_count,] row_count | row_count OFFSET offset_count}]
[INTO OUTFILE 'file_name']
```

The Doris SELECT syntax is basically the same as MySQL.

## SQL Function

Doris Function covers most MySQL functions.

## SQL Mode

Name	Behavior when enabled	Behavior when disabled	Notes
PIPES_AS_CONCAT	Parses <code>\\ </code> as the concat function	Parses <code>\\ </code> as the logical AND operator	-
NO_BACKSLASH_ESCAPES	Treats backslashes in strings as literal characters	Treats backslashes in strings as escape characters	-

# Join

---

## What is JOIN

In relational databases, data is distributed across multiple tables, which are interconnected through specific relationships. SQL JOIN operations allow users to combine different tables into a more complete result set based on these relationships.

## JOIN types supported by Doris

- **INNER JOIN:** Comparing each row of the left table with all rows of the right table based on the JOIN condition, returning matching rows from both tables. For more details, refer to the syntax definition for JOIN queries in [SELECT](#).
- **LEFT JOIN:** Building on the result set of an INNER JOIN, if a row from the left table does not have a match in the right table, all rows from the left table are returned, with corresponding columns from the right table shown as NULL.
- **RIGHT JOIN:** The opposite of LEFT JOIN; if a row from the right table does not have a match in the left table, all rows from the right table are returned, with corresponding columns from the left table shown as NULL.
- **FULL JOIN:** Building on the result set of an INNER JOIN, returning all rows from both tables, filling in NULL where there are no matches.
- **CROSS JOIN:** Having no JOIN condition, returning the Cartesian product of the two tables, where each row from the left table is combined with each row from the right table.
- **LEFT SEMI JOIN:** Comparing each row of the left table with all rows of the right table based on the JOIN condition. If a match exists, the corresponding row from the left table is returned.
- **RIGHT SEMI JOIN:** The opposite of LEFT SEMI JOIN; comparing each row of the right table with all rows of the left table, returning the corresponding row from the right table if a match exists.
- **LEFT ANTI JOIN:** Comparing each row of the left table with all rows of the right table based on the JOIN condition. If there is no match, the corresponding row from the left table is returned.
- **RIGHT ANTI JOIN:** The opposite of LEFT ANTI JOIN; comparing each row of the right table with all rows of the left table, returning rows from the right table that do not have matches.
- **NULL AWARE LEFT ANTI JOIN:** Similar to LEFT ANTI JOIN but ignoring rows in the left table where the matching column is NULL.

## Implementation of JOIN in Doris

Doris supports two implementation methods for JOIN: **Hash Join** and **Nested Loop Join**.

- **Hash Join:** A hash table is built on the right table based on the equality JOIN columns, and the data from the left table is streamed through this hash table for JOIN calculations. This method is limited to cases where equality JOIN conditions are applicable.
- **Nested Loop Join:** This method uses two nested loops, driven by the left table, to iterate through each row of the left table and compare it with every row of the right table based on the JOIN condition. It is suitable for all JOIN scenarios, including those that Hash Join cannot handle, such as queries involving GREATER THAN or LESS THAN comparisons, or cases requiring Cartesian products. However, compared to Hash Join, Nested Loop Join may have inferior performance.

## Implementation of Hash Join in Doris

As a distributed MPP database, Apache Doris requires data shuffling during the Hash Join process to ensure the correctness of the JOIN results. Below are several data shuffling methods:

**Broadcast Join** As illustrated, the Broadcast Join process involves sending all data from the right table to all nodes participating in the JOIN computation, including the nodes scanning the left table's data, while the left table's data remains stationary. In this process, each node receives a complete copy of the right table's data (with a total volume of  $T(R)$ ) to ensure that all nodes have the necessary data to perform the JOIN operation.

This method is suitable for various scenarios but is not applicable for RIGHT OUTER, RIGHT ANTI, and RIGHT SEMI types of Hash Join. Its network overhead is calculated as the number of JOIN nodes  $N$  multiplied by the volume of right table's data  $T(R)$ .

Implementation of Hash Join in Doris

## Partition Shuffle Join

This method computes hash values based on the JOIN conditions and performs bucketing. Specifically, the data from both the left and right tables is partitioned according to the hash values calculated from the JOIN conditions, and these partitioned data sets are then sent to the corresponding partition nodes (as illustrated).

The network overhead of this method mainly includes two parts: the cost of transferring the left table's data  $T(S)$  and the cost of transferring the right table's data  $T(R)$ . This method only supports Hash Join operations because it relies on the JOIN conditions to perform data bucketing.

Partition Shuffle Join

## Bucket Shuffle Join

When the JOIN condition includes the bucketed column from the left table, the left table's data location remains unchanged while the right table's data is distributed to the left table's nodes for the JOIN, reducing network overhead.

When one side of the table involved in the JOIN operation has its data already hash-distributed according to the JOIN condition column, users can choose to keep this side's data location unchanged while distributing the other side's data based on the same JOIN condition column and hash distribution. (The term "table" here refers not only to physically stored tables but also to the output results of any operators in SQL queries. Users can flexibly choose to keep either the left or right table's data location unchanged while only moving and distributing the other side's table.)

For example, in the case of physical tables of Doris, since the table data is stored in a bucketed manner through hash computation, users can directly leverage this feature to optimize the data shuffle process for the JOIN operation. Suppose you have two tables that need to be joined, and the JOIN column is the bucketed column from the left table. In this case, you do not need to move the left table's data; you only need to distribute the right table's data to the appropriate locations based on the left table's bucket information to complete the JOIN computation.

The primary network overhead for this process comes from the movement of the right table's data, denoted as  $T(R)$ .

Bucket Shuffle Join

## Colocate Join

Similar to Bucket Shuffle Join, if both tables involved in the Join are already distributed by Hash according to the Join condition columns, the Shuffle process can be skipped, and the Join calculation can be performed directly on the local data. This can be illustrated with physical tables:

When creating a table in Doris with the specification of DISTRIBUTED BY HASH, the system distributes data based on the Hash distribution key during data import. If the Hash distribution keys of both tables happen to match the Join condition columns, it can be said that the data in these two tables is already pre-distributed according to the Join requirements, eliminating the need for additional Shuffle operations. Therefore, during actual queries, the Join calculation can be executed directly on these two tables.

**For scenarios where Join is executed after directly scanning data, certain conditions must be met during table creation; please refer to the subsequent restrictions regarding Colocate Join between the two physical tables.**

Colocate Join

## Bucket Shuffle Join VS Colocate Join

As mentioned earlier, for both Bucket Shuffle Join and Colocate Join, the join operations can be executed as long as the distribution of the participating tables meets specific conditions (the term “tables” here refers to any output from SQL query operators).

Next, we will provide a more detailed explanation of the generalized Bucket Shuffle Join and Colocate Join using two tables, t1 and t2, along with relevant SQL examples. First, here are the table creation statements for both tables:

```
create table t1
(
 c1 bigint,
 c2 bigint
)
DISTRIBUTED BY HASH(c1) BUCKETS 3
PROPERTIES ("replication_num" = "1");

create table t2
(
 c1 bigint,
 c2 bigint
)
DISTRIBUTED BY HASH(c1) BUCKETS 3
PROPERTIES ("replication_num" = "1");
```

### Example of Bucket Shuffle Join

In the following example, both tables t1 and t2 have been processed by the GROUP BY operator, resulting in new tables (at this point, the tx table is hash-distributed by c1, while the ty table is hash-distributed by c2). The subsequent JOIN condition is tx.c1 = ty.c2, which perfectly meets the conditions for a Bucket Shuffle Join.

```
explain select *
from
(
 -- The t1 table is hash-distributed by c1, and after the GROUP BY operator, it still maintains the
 hash distribution by c1.
 select c1 as c1, sum(c2) as c2
 from t1
 group by c1
) tx
join
(
 -- The t2 table is hash-distributed by c1, but after the GROUP BY operator, the data is redistributed
 to be hash-distributed by c2.
 select c2 as c2, sum(c1) as c1
 from t2
 group by c2
) ty
on tx.c1 = ty.c2;
```

From the following Explain execution plan, it can be observed that the left child node of the Hash Join node 7 is the aggregation node 6, while the right child node is the Exchange node 4. This indicates that the data from the left child node, after aggregation, remains in the same location, while the data from the right child node is

distributed to the node where the left child node resides using the Bucket Shuffle method, in order to perform the subsequent Hash Join operation.

```

## Example of Colocate Join

In the following example, both tables t1 and t2 have been processed by the GROUP BY operator, resulting in new tables (at this point, both tx and ty are hash-distributed by c2). The subsequent JOIN condition is tx.c2 = ty.c2, which perfectly meets the conditions for a Colocate Join.

```

explain select *
from
(
 -- The t1 table is initially hash-distributed by c1, but after the GROUP BY operator, the data
 distribution changes to be hash-distributed by c2.
 select c2 as c2, sum(c1) as c1
 from t1
 group by c2
) tx
join
(
 -- The t2 table is initially hash-distributed by c1, but after the GROUP BY operator, the data
 distribution changes to be hash-distributed by c2.

```

```

 select c2 as c2, sum(c1) as c1
 from t2
 group by c2
) ty
on tx.c2 = ty.c2;

```

From the results of the following Explain execution plan, it can be seen that the left child node of Hash Join node 8 is aggregation node 7, and the right child node is aggregation node 3, with no Exchange node present. This indicates that the aggregated data from both the left and right child nodes remains in its original location, eliminating the need for data movement and allowing the subsequent Hash Join operation to be performed directly locally.

## Comparison of four shuffle methods

Shuffle Methods	Network Overhead	Physical Operator	Applicable Scenarios
Broadcast	$N * T(R)$	Hash Join /Nest Loop Join	General
Shuffle	$T(S) + T(R)$	Hash Join	General
Bucket Shuffle	$T(R)$	Hash Join	JOIN condition includes the left table's bucketed column, with the left table being single-partitioned.
Colocate	0	Hash Join	JOIN condition includes the left table's bucketed column, and both tables belong to the same Colocate Group.

### NOTE

N: Number of instances participating in the Join calculation

T(Relation): Number of tuples in the relation

The flexibility of the four Shuffle methods decreases in order, and their requirements for data distribution become increasingly strict. In most cases, as the requirements for data distribution increase, the performance of Join calculations tends to improve gradually. It is important to note that if the number of buckets in a table is small, Bucket Shuffle or Colocate Join may experience a decrease in performance due to lower parallelism, potentially resulting in slower performance than Shuffle Join. This is because the Shuffle operation can more effectively balance data distribution, thereby providing higher parallelism in subsequent processing.

## FAQ

Bucket Shuffle Join and Colocate Join have specific limitations regarding data distribution and JOIN conditions when applied. Below, we will elaborate on the specific restrictions for each of these JOIN methods.

### Limitations of Bucket Shuffle Join

When directly scanning two physical tables for a Bucket Shuffle Join, the following conditions must be met:

- Equality Join condition:** Bucket Shuffle Join is only applicable for scenarios where the JOIN condition is based on equality, as it relies on hash calculations to determine data distribution.
- Inclusion of bucketed columns in equality conditions:** The equality JOIN condition must include the bucketed columns from both tables. When the left table's bucketed column is used as the equality JOIN condition, it is more likely to be planned as a Bucket Shuffle Join.
- Table type restrictions:** Bucket Shuffle Join is only applicable to native OLAP tables in Doris. For external tables such as ODBC, MySQL, and ES, Bucket Shuffle Join cannot be effective when they are used as the left table.
- Single Partition Requirement:** For partitioned tables, since the data distribution may differ across partitions, Bucket Shuffle Join is only guaranteed to be effective when the left table is a single partition.

Therefore, when executing SQL, it is advisable to use WHERE conditions to enable partition pruning strategies whenever possible.

## Limitations of Colocate Join

When directly scanning two physical tables, Colocate Join has stricter limitations compared to Bucket Shuffle Join. In addition to meeting all the conditions for Bucket Shuffle Join, the following requirements must also be satisfied:

1. **bucket column types and counts are Same:** Not only must the types of the bucketed columns match, but the number of buckets must also be the same to ensure data distribution consistency.
2. **Explicit specification of Colocation Group:** A Colocation Group must be explicitly specified; only tables within the same Colocation Group can participate in a Colocate Join.
3. **Unstable state during replica repair or balancing:** During operations such as replica repair or balancing, the Colocation Group may be in an unstable state. In this case, the Colocate Join will degrade to a regular Join operation.

# Subquery

---

A Subquery is an SQL query nested within another query (usually a SELECT statement). It can be used in the SELECT, FROM, WHERE, or HAVING clauses to provide data or conditions for the outer query. The use of subqueries makes SQL queries more flexible and powerful, as they allow us to solve more complex problems within a single query.

Some important features of subqueries are as follows:

1. **Position of Subqueries:** Subqueries can be placed in multiple SQL clauses, such as the WHERE clause, HAVING clause, and FROM clause. They can be used with SELECT, UPDATE, INSERT, DELETE statements, and expression operators (such as comparison operators =, >, <, <=, as well as IN, EXISTS, etc.).
2. **Relationship between Main Query and Subquery:** A subquery is a query nested inside another query. The outer query is referred to as the main query, while the inner query is referred to as the subquery.
3. **Execution Order:** When there is no correlation between the subquery and the main query, the subquery is usually executed first. When there is a correlation, the parser decides which query to execute first in real-time as needed and uses the output of the subquery accordingly.
4. **Use of Parentheses:** Subqueries must be enclosed in parentheses to distinguish them as nested within another query.

Below, we will use tables t1 and t2 and related SQL to introduce the basic features and usage of subqueries. The table creation statements are as follows:

```
create table t1
(
 c1 bigint,
 c2 bigint
)
DISTRIBUTED BY HASH(c1) BUCKETS 3
PROPERTIES ("replication_num" = "1");

create table t2
(
 c1 bigint,
 c2 bigint
)
DISTRIBUTED BY HASH(c1) BUCKETS 3
PROPERTIES ("replication_num" = "1");
```

## Classification of Subqueries

### Classification Based on the Characteristics of Data Returned by Subqueries

Subqueries can be classified into scalar and non-scalar subqueries based on the characteristics of the data they return:

## 1. Scalar Subquery

A subquery that always returns a single value (essentially equivalent to a one-row, one-column Relation). If the subquery does not return any data, it returns a NULL value. Scalar subqueries can theoretically appear anywhere a single-value expression is allowed.

## 2. Non-scalar Subquery

A subquery that returns a Relation (different from the return value of a scalar subquery, this Relation can contain multiple rows and columns). If the subquery does not return any data, it returns an empty set (0 rows). Non-scalar subqueries can theoretically appear anywhere a relation (set) is allowed.

The following examples illustrate scalar and non-scalar subqueries (for the two subqueries in parentheses, when t2 is an empty table, the results returned by the two subqueries are different):

```
-- Scalar subquery, when t2 is an empty table, the subquery returns the scalar value null
select * from t1 where t1.c1 > (select sum(t2.c1) from t2);

-- Non-scalar subquery, when t2 is an empty table, the subquery returns an empty set (0 rows)
select * from t1 where t1.c1 in (select t2.c1 from t2);
```

## Classification Based on Whether the Subquery References Columns from the Outer Query

Subqueries can be classified into correlated subqueries and non-correlated subqueries based on whether they reference columns from the outer query:

### 1. Non-correlated Subquery

A subquery that does not reference any columns from the outer query. Non-correlated subqueries can often be computed independently and return the corresponding results once for the outer query to use.

### 2. Correlated Subquery

A subquery that references one or more columns from the main query (also known as the outer query) (the referenced outer columns are often in the WHERE condition of the subquery). Correlated subqueries can often be seen as a filtering operation on the externally associated table, as for each row of data in the outer table, the subquery is computed and returns the corresponding result.

The following examples illustrate correlated and non-correlated subqueries:

```
-- Correlated subquery, the subquery internally uses the column t1.c2 from the outer table
select * from t1 where t1.c1 in (select t2.c1 from t2 where t2.c2 = t1.c2);

-- Non-correlated subquery, the subquery internally does not use any columns from the outer table t1
select * from t1 where t1.c1 in (select t2.c1 from tt2);
```

## Subqueries Supported by Doris

Doris supports all non-correlated subqueries and provides partial support for correlated subqueries as follows:

- Supports correlated scalar subqueries in the WHERE and HAVING clauses.

- Supports correlated IN, NOT IN, EXISTS, NOT EXISTS non-scalar subqueries in the WHERE and HAVING clauses.
- Supports correlated scalar subqueries in the SELECT list.
- For nested subqueries, Doris only supports subqueries correlated to their immediate parent query and does not support cross-level correlation to outer queries beyond the parent.

## Limitations of Correlated Subqueries

### Limitations of Correlated Scalar Subqueries

- The correlation condition must be an equality condition.
- The output of the subquery must be the result of a single aggregate function without a GROUP BY clause.

```
-- Single aggregate function without GROUP BY, supported
select * from t1 where t1.c1 < (select max(t2.c1) from t2 where t1.c2 = t2.c2);

-- Equivalent rewritten SQL as follows:
select t1.* from t1 inner join (select t2.c2 as c2, max(t2.c1) as c1 from t2 group by t2.c2) tx on t1.c1 < tx.c1 and t1.c2 = tx.c2;

-- Non-equality condition, not supported
select * from t1 where t1.c1 = (select max(t2.c1) from t2 where t1.c2 > t2.c2);

-- No aggregate function, not supported
select * from t1 where t1.c1 = (select t2.c1 from t2 where t1.c2 = t2.c2);

-- With aggregate function but includes GROUP BY, not supported
select * from t1 where t1.c1 = (select max(t2.c1) from t2 where t1.c2 = t2.c2 group by t2.c2);
```

### Limitations of Correlated (NOT) EXISTS Subqueries

- The subquery cannot have both OFFSET and LIMIT.

```
-- With LIMIT but no OFFSET, supported
select * from t1 where exists (select t2.c1 from t2 where t1.c2 = t2.c2 limit 2);

-- Equivalent rewritten SQL as follows:
select * from t1 left semi join t2 on t1.c2 = t2.c2;

-- With OFFSET and LIMIT, not supported
select * from t1 where exists (select t2.c1 from t2 where t1.c2 = t2.c2 limit 2, 3);
```

### Limitations of Correlated (NOT) IN Subqueries

- The output of the subquery must be a single column.
- The subquery cannot have LIMIT.
- The subquery cannot have aggregate functions or GROUP BY clauses.

```

-- Supported subquery
select * from t1 where t1.c1 in (select t2.c1 from t2 where t1.c2 = t2.c2);

-- Equivalent rewritten SQL as follows:
select * from t1 left semi join t2 on t1.c1 = t2.c1 and t1.c2 = t2.c2;

-- Subquery output is multiple columns, not supported
select * from t1 where (t1.a, t1.c) in (select t2.c1, t2.c from t2 where t1.c2 = t2.c2);

-- Subquery with LIMIT, not supported
select * from t1 where t1.c1 in (select t2.c1 from t2 where t1.c2 = t2.c2 limit 3);

-- With GROUP BY clause, not supported
select * from t1 where t1.c1 in (select t2.c1 from t2 where t1.c2 = t2.c2 group by t2.c1);

-- With aggregate function, not supported
select * from t1 where t1.c1 in (select sum(t2.c1) from t2 where t1.c2 = t2.c2);

```

## Limitations of Nested Subqueries

Currently, only subqueries that correlate directly with their immediate parent queries are supported. Correlation with outer layers of the parent query is not supported.

Assume there is another table t3 with the following creation statement:

```

create table t3
(
 c1 bigint,
 c2 bigint
)
DISTRIBUTED BY HASH(c1) BUCKETS 3
PROPERTIES ("replication_num" = "1");

```

- Supported when the subquery only uses columns from its immediate parent query:

```

select
 t1.c1
from
 t1
where not exists (
 select
 t2.c1
 from
 t2
 where not exists (
 select
 t3.c1
 from
 t3
 where
 t3.c2 = t2.c2
) and t2.c2 = t1.c2
);

```

- Not supported when the innermost subquery uses columns from its immediate parent query t2.c2 and also columns from the outermost query t1.c1:

```

select
 t1.c1
from
 t1
where not exists (
 select
 t2.c1
 from
 t2
 where not exists (
 select
 t3.c1
 from
 t3
 where
 t3.c2 = t2.c2 and t3.c1 = t1.c1
)
);

```

## Mark Join

In where conditions, clauses with or relationships composed of subqueries using (not) in or (not) exists and other filtering conditions require special handling to produce correct results. An example is given below:

```

select
 t1.c1,
 t1.c2
from t1
where exists (
 select
 t2.c1
 from t2
 where
 t1.c2 = t2.c2
) or t1.c1 > 0;

```

If the exists clause in this SQL is directly implemented using left semi join, according to the semantics of left semi join, only rows from t1 that satisfy  $t1.c2 = t2.c2$  will be output. However, rows that actually satisfy the condition  $t1.c1 > 0$  should also be output. To achieve this, the mechanism of Mark Join is introduced.

### Note

right semi join is similar but differs in the left and right tables. Here, we use left semi join as an example.

Example SQL is as follows:

```

-- This SQL cannot be executed and is only for demonstration purposes
select
 tx.c1,
 tx.c2
from
 (

```

```

select
 t1.c1,
 t1.c2,
 mark_join_flag
from
 t1 left (mark) semi join t2 on t1.c2 = t2.c2
) tx
where
 tx.mark_join_flag or tx.c1 > 0;

```

The difference between Mark Join and a regular left semi join is that a regular left semi join directly outputs rows from the left table that meet the condition, while Mark Join outputs the original left table with an additional flag column (the `mark_join_flag` in the example) that can be true, false, or null. The value of the flag is determined by the join condition expression `t1.c2 = t2.c2`, with each row corresponding to a flag value. The calculation of flag values is shown in the table below:

t1.c1	t2.c1	mark_join_flag
1	1	TRUE
1	2	FALSE
1	NULL	NULL
NULL	1	NULL
NULL	NULL	NULL

With this flag, the where filtering condition can be rewritten as `where mark_join_flag or t1.c1 > 0` to obtain the correct results.

## Usage notes

Since the output of a scalar subquery must be a single value, a runtime error will be reported when the subquery returns more than one row of data.

### For Correlated Scalar Subqueries

When using a correlated quantifier subquery, if the subquery that satisfies the correlation condition returns more than one row of data, a runtime error will be reported.

Please refer to the following SQL example:

```

-- If there are more than 1 row in the t2 table that satisfies t1.c2 = t2.c2 in the associated scalar
subquery, a runtime error will be reported
select t1.*, (select t2.c1 from t2 where t1.c2 = t2.c2) from t1;

-- Example error message
ERROR 1105 (HY000): errCode = 2, detailMessage = (127.0.0.1)[INVALID_ARGUMENT][E33] correlate scalar subquery
must return only 1 row

```

## For Non-Correlated Scalar Subqueries

Doris will add an `assert num rows` operator at runtime. If the subquery returns more than one row of data, a runtime error will be reported.

Please refer to the following SQL example:

```
-- Non-correlated scalar subquery, will report an error if table t2 has more than 1 row of data
select t1.*, (select t2.c1 from t2) from t1;

-- Example error message
ERROR 1105 (HY000): errCode = 2, detailMessage = (127.0.0.1)[CANCELLED]Expected EQ 1 to be returned by
expression
```

# Multi-Dimensional Analytics

---

In a database, ROLLUP, CUBE, and GROUPING SETS are advanced SQL statements used for multidimensional data aggregation. These features significantly enhance the capabilities of the GROUP BY clause, enabling users to obtain multiple levels of summary results in a single query, which is semantically equivalent to using UNION ALL to connect multiple aggregation statements.

- **ROLLUP:** ROLLUP is an operation used to generate hierarchical summaries. It aggregates data according to the specified column order, gradually summarizing from the finest granularity to the highest level. For example, in sales data, ROLLUP can be used to summarize by region and time, providing sales for each region per month, total sales for each region, and overall total sales. ROLLUP is suitable for scenarios requiring step-by-step summaries.
- **CUBE:** CUBE is a more powerful aggregation operation that generates all possible summary combinations. Unlike ROLLUP, CUBE calculates subsets for all dimensions. For instance, for sales data aggregated by product and region, CUBE will compute sales for each product in each region, total sales for each product, total sales for each region, and overall total sales. CUBE is applicable to scenarios requiring comprehensive multidimensional analysis, such as business analysis and market research.
- **GROUPING SETS:** GROUPING SETS offer flexibility in aggregating specific grouping sets. It allows users to specify a set of column combinations for independent aggregation, rather than generating all possible combinations as in ROLLUP and CUBE. For example, one can define summaries for specific combinations of region and time without needing all combinations of each dimension. GROUPING SETS are suitable for scenarios requiring customized summaries, providing flexible aggregation control.

ROLLUP, CUBE, and GROUPING SETS provide powerful multidimensional data summary functions, catering to various data analysis and reporting needs, and making complex aggregation calculations simpler and more efficient. The following sections will detail the usage scenarios, syntax, and examples of these features.

## ROLLUP

### Use Case

ROLLUP is particularly useful for summarizing data along hierarchical dimensions such as time, geography, and category. For instance, queries can specify ROLLUP(year, month, day) or (country, Province, city).

### Syntax and Example

The syntax for ROLLUP is as follows:

```
SELECT ... GROUP BY ROLLUP(grouping_column_reference_list)
```

Here's an example query that analyzes sales sums by year and month:

```

SELECT
 YEAR(d_date),
 MONTH(d_date),
 SUM(ss_net_paid) AS total_sum
FROM
 store_sales,
 date_dim d1
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND YEAR(d_date) IN (2001, 2002)
 AND MONTH(d_date) IN (1, 2, 3)
GROUP BY
 ROLLUP(YEAR(d_date), MONTH(d_date))
ORDER BY
 YEAR(d_date), MONTH(d_date);

```

This query summarizes data by time, calculating subtotals for sales by year, sales by month within each year, and the grand total of sales. The query result is as follows:

```

+-----+-----+-----+
| YEAR(d_date) | MONTH(d_date) | total_sum |
+-----+-----+-----+
| NULL | NULL | 54262669.17 |
| 2001 | NULL | 26640320.46 |
| 2001 | 1 | 9982165.83 |
| 2001 | 2 | 8454915.34 |
| 2001 | 3 | 8203239.29 |
| 2002 | NULL | 27622348.71 |
| 2002 | 1 | 11260654.35 |
| 2002 | 2 | 7722750.61 |
| 2002 | 3 | 8638943.75 |
+-----+-----+-----+
9 rows in set (0.08 sec)

```

## CUBE

### Use Case

CUBE is best suited for queries involving columns from multiple independent dimensions, rather than columns representing different levels of a single dimension. For example, a common usage scenario is summarizing all combinations of month, region, and product. These are three independent dimensions, and it is common to analyze all possible subtotal combinations. By contrast, cross-tabulating all possible combinations of year, month, and day would include several unnecessary values due to the natural hierarchy in the time dimension. In most analyses, subtotals like profits calculated by month and day are unnecessary. Relatively few users need to ask, “What is the total sales for the 16th of each month throughout the year?”

### Syntax and Example

The syntax for CUBE is as follows:

```

SELECT ... GROUP BY CUBE(grouping_column_reference_list)

```

Example usage:

```

SELECT
 YEAR(d_date),
 i_category,
 ca_state,
 SUM(ss_net_paid) AS total_sum
FROM
 store_sales,
 date_dim d1,
 item,
 customer_address ca
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND ss_addr_sk = ca_address_sk
 AND i_category IN ("Books", "Electronics")
 AND YEAR(d_date) IN (1998, 1999)
 AND ca_state IN ("LA", "AK")
GROUP BY CUBE(YEAR(d_date), i_category, ca_state)
ORDER BY YEAR(d_date), i_category, ca_state;

```

The query result is as follows, calculating:

- The total sales sum;
- Subtotals for sales by year, by product category, and by state;
- Subtotals for sales by product category within each year, by state for each product, by state within each year, and by product category within each state and year.

YEAR(d_date)	i_category	ca_state	total_sum
NULL	NULL	NULL	8690374.60
NULL	NULL	AK	2675198.33
NULL	NULL	LA	6015176.27

1999	Electronics	AK	681779.07
1999	Electronics	LA	1614465.52

27 rows in set (0.21 sec)

## GROUPING FUNCTION

This section introduces how to address two challenges when using ROLLUP and CUBE:

1. How to programmatically identify which rows in the result set represent subtotals and accurately determine the aggregation level corresponding to a given subtotal. Since subtotals are often needed for calculations such as percentage of totals, we require a convenient method to identify these subtotal rows.
2. When the query results contain both actual stored NULL values and “NULL” values generated by ROLLUP or CUBE operations, another problem arises: how to distinguish between these two types of NULL values?

GROUPING, GROUPING\_ID, and GROUPING SETS can effectively solve the aforementioned challenges.

### GROUPING

#### 1. Principles

GROUPING uses a single column as a parameter and returns 1 when encountering a NULL value created by ROLLUP or CUBE operations, indicating that the row is a subtotal. Any other type of value (including NULLs inherently present in the table data) returns 0.

Example:

```
select
 year(d_date),
 month(d_date),
 sum(ss_net_paid) as total_sum,
 grouping(year(d_date)),
 grouping(month(d_date))
from
 store_sales,
 date_dim d1
where
 d1.d_date_sk = ss_sold_date_sk
 and year(d_date) in (2001, 2002)
 and month(d_date) in (1, 2, 3)
group by
 rollup(year(d_date), month(d_date))
order by
 year(d_date), month(d_date);
```

- The GROUPING function result for the (YEAR(d\_date), MONTH(d\_date)) group is (0,0) for aggregation by year and month.
- The GROUPING function result for the (YEAR(d\_date)) group is (0,1) for aggregation by year.
- The GROUPING function result for the () group is (1,1) for the total aggregation.

Query result:

```
+-----+-----+-----+-----+-----+
| year(d_date) | month(d_date) | total_sum | Grouping(year(d_date)) | Grouping(month(d_date)) |
+-----+-----+-----+-----+-----+
```

	NULL		NULL		54262669.17		1		1	
	2001		NULL		26640320.46		0		1	
	2001		1		9982165.83		0		0	
	2001		2		8454915.34		0		0	
	2001		3		8203239.29		0		0	
	2002		NULL		27622348.71		0		1	
	2002		1		11260654.35		0		0	
	2002		2		7722750.61		0		0	
	2002		3		8638943.75		0		0	

9 rows in set (0.06 sec)

## 2. Usage Scenarios, Syntax, and Examples

The GROUPING function can be used to filter results. Example:

```
select
 year(d_date),
 i_category,
 ca_state,
 sum(ss_net_paid) as total_sum
from
 store_sales,
 date_dim d1,
 item,
 customer_address ca
where
 d1.d_date_sk = ss_sold_date_sk
 and i_item_sk = ss_item_sk
 and ss_addr_sk=ca_address_sk
 and i_category in ("Books", "Electronics")
 and year(d_date) in(1998, 1999)
 and ca_state in ("LA", "AK")
group by cube(year(d_date), i_category, ca_state)
having grouping(year(d_date))=1 and grouping(i_category)=1 and grouping(ca_state)=1
or grouping(year(d_date))=0 and grouping(i_category)=1 and grouping(ca_state)=1
or grouping(year(d_date))=1 and grouping(i_category)=1 and grouping(ca_state)=0
order by year(d_date), i_category, ca_state;
```

Using the GROUPING function in the HAVING clause retains only the total sales, sales summarized by year, and sales summarized by region. Query result:

year('d1'.`d_date`)	i_category	ca_state	total_sum
NULL	NULL	NULL	8690374.60
NULL	NULL	AK	2675198.33
NULL	NULL	LA	6015176.27
1998	NULL	NULL	4369656.14
1999	NULL	NULL	4320718.46

5 rows in set (0.13 sec)

You can also use the GROUPING function with the IF function to enhance query readability. Example:

```
select
 if(grouping(year(d_date)) = 1, "Multi-year sum", year(d_date)) as year,
 if(grouping(i_category) = 1, "Multi-category sum", i_category) as category,
 sum(ss_net_paid) as total_sum
```

```

from
 store_sales,
 date_dim d1,
 item,
 customer_address ca
where
 d1.d_date_sk = ss_sold_date_sk
 and i_item_sk = ss_item_sk
 and ss_addr_sk = ca_address_sk
 and i_category in ("Books", "Electronics")
 and year(d_date) in (1998, 1999)
 and ca_state in ("LA", "AK")
group by cube(year(d_date), i_category)

```

Query result:

```

+-----+-----+-----+
| year | category | total_sum |
+-----+-----+-----+
| 1998 | Books | 2213703.82 |
| 1998 | Electronics | 2155952.32 |
| 1999 | Electronics | 2296244.59 |
| 1999 | Books | 2024473.87 |
| 1998 | Multi-category sum | 4369656.14 |
| 1999 | Multi-category sum | 4320718.46 |
| Multi-year sum | Books | 4238177.69 |
| Multi-year sum | Electronics | 4452196.91 |
| Multi-year sum | Multi-category sum | 8690374.60 |
+-----+-----+-----+
9 rows in set (0.09 sec)

```

## GROUPING\_ID

### 1. Usage Scenarios

In a database, both GROUPING\_ID and GROUPING functions serve as auxiliary functions for handling multidimensional data aggregation queries, such as ROLLUP and CUBE, aiding users in distinguishing between different levels of aggregation results. If you wish to determine the aggregation level of a particular row, you need to use the GROUPING function to compute all GROUP BY columns, as the computation result of a single column alone is insufficient.

The GROUPING\_ID function is more powerful than GROUPING because it can detect multiple columns simultaneously. The GROUPING\_ID function accepts multiple columns as parameters and returns an integer that represents the aggregation status of these columns through binary bits. When using tables or materialized views to store computation results, using GROUPING to represent different levels of aggregation can consume considerable storage space. In such scenarios, GROUPING\_ID is more appropriate.

Taking CUBE(a, b) as an example, its GROUPING\_ID can be represented as follows:

Aggregation Level	Bit Vector	GROUPING_ID	GROUPING(a)	GROUPING(b)
a,b	0 0	0	0	0
a	0 1	1	0	1
b	1 0	2	1	0

Aggregation Level	Bit Vector	GROUPING_ID	GROUPING(a)	GROUPING(b)
Grand Total	1 1	3	1	1

## 2. Syntax and Example

Here is an example SQL query:

```
SELECT
 year(d_date),
 i_category,
 SUM(ss_net_paid) AS total_sum,
 GROUPING(year(d_date)),
 GROUPING(i_category),
 GROUPING_ID(year(d_date), i_category)
FROM
 store_sales,
 date_dim d1,
 item,
 customer_address ca
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND ss_addr_sk = ca_address_sk
 AND i_category IN ('Books', 'Electronics')
 AND year(d_date) IN (1998, 1999)
 AND ca_state IN ('LA', 'AK')
GROUP BY CUBE(year(d_date), i_category);
```

The query results are as follows:

```
+-----+-----+-----+-----+-----+
+-----+
| year(d_date) | i_category | total_sum | GROUPING(year(d_date)) | GROUPING(i_category) |
GROUPING_ID(year(d_date), i_category) |
+-----+-----+-----+-----+-----+
+-----+
| 1998 | Electronics | 2155952.32 | 0 | 0 | 0
|
| 1998 | Books | 2213703.82 | 0 | 0 | 0
|
| 1999 | Electronics | 2296244.59 | 0 | 0 | 0
|
| 1999 | Books | 2024473.87 | 0 | 0 | 0
|
| 1998 | NULL | 4369656.14 | 0 | 1 | 1
|
| 1999 | NULL | 4320718.46 | 0 | 1 | 1
|
| NULL | Electronics | 4452196.91 | 1 | 0 | 2
|
| NULL | Books | 4238177.69 | 1 | 0 | 2
|
| NULL | NULL | 8690374.60 | 1 | 1 | 3
|
+-----+-----+-----+-----+-----+
+-----+
9 rows in set (0.12 sec)
```

## GROUPING SETS

### 1. Usage Scenarios

When there is a need to selectively specify the group sets to create, the `GROUPING SETS` expression can be used in the `GROUP BY` clause. This method allows users to precisely specify across multiple dimensions without computing the entire CUBE.

Since CUBE queries typically consume significant resources, using `GROUPING SETS` can enhance query execution efficiency when only a few dimensions are of interest.

### 2. Syntax and Examples

The syntax for `GROUPING SETS` is as follows:

```
SELECT ... GROUP BY GROUPING SETS(grouping_column_reference_list)
```

If you need:

- Subtotals of sales for each product category per year
- Subtotals of sales for each state per year
- Subtotals of sales for each product in each state per year

You can use `GROUPING SETS` to specify these dimensions and perform the aggregation. Here is an example:

```
SELECT
 YEAR(d_date),
 i_category,
 ca_state,
 SUM(ss_net_paid) AS total_sum
FROM
 store_sales,
 date_dim d1,
 item,
 customer_address ca
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND ss_addr_sk = ca_address_sk
 AND i_category IN ('Books', 'Electronics')
 AND YEAR(d_date) IN (1998, 1999)
 AND ca_state IN ('LA', 'AK')
GROUP BY GROUPING SETS(
 (YEAR(d_date), i_category),
 (YEAR(d_date), ca_state),
 (YEAR(d_date), ca_state, i_category)
)
ORDER BY YEAR(d_date), i_category, ca_state;
```

Query Result:

YEAR(d_date)	i_category	ca_state	total_sum
1998	NULL	AK	1402539.19

1998	NULL	LA	2967116.95
1998	Books	NULL	2213703.82
1998	Books	AK	719911.29
1998	Books	LA	1493792.53
1998	Electronics	NULL	2155952.32
1998	Electronics	AK	682627.90
1998	Electronics	LA	1473324.42
1999	NULL	AK	1272659.14
1999	NULL	LA	3048059.32
1999	Books	NULL	2024473.87
1999	Books	AK	590880.07
1999	Books	LA	1433593.80
1999	Electronics	NULL	2296244.59
1999	Electronics	AK	681779.07
1999	Electronics	LA	1614465.52

16 rows in set (0.11 sec)

The above approach is equivalent to using CUBE but specifies concrete grouping\_id, thereby reducing unnecessary calculations:

```
SELECT
 SUM(ss_net_paid) AS total_sum,
 YEAR(d_date),
 i_category,
 ca_state
FROM
 store_sales,
 date_dim d1,
 item,
 customer_address ca
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND ss_addr_sk = ca_address_sk
 AND i_category IN ('Books', 'Electronics')
 AND YEAR(d_date) IN (1998, 1999)
 AND ca_state IN ('LA', 'AK')
GROUP BY CUBE(YEAR(d_date), ca_state, i_category)
HAVING grouping_id(YEAR(d_date), ca_state, i_category) = 0
 OR grouping_id(YEAR(d_date), ca_state, i_category) = 2
 OR grouping_id(YEAR(d_date), ca_state, i_category) = 1;
```

### Note

Using CUBE computes all possible aggregation levels (eight in this case), but in practice, you may only be interested in a few of them.

## 3. Semantic Equivalents

- GROUPING SETS vs. GROUP BY UNION ALL

The GROUPING SETS statement:

```
SELECT k1, k2, SUM(k3) FROM t GROUP BY GROUPING SETS ((k1, k2), (k1), (k2), ());
```

Is equivalent in query results to multiple GROUP BY queries connected with UNION ALL:

```
SELECT k1, k2, SUM(k3) FROM t GROUP BY k1, k2
UNION ALL
SELECT k1, NULL, SUM(k3) FROM t GROUP BY k1
UNION ALL
SELECT NULL, k2, SUM(k3) FROM t GROUP BY k2
UNION ALL
SELECT NULL, NULL, SUM(k3) FROM t;
```

Using UNION ALL results in a longer query and requires multiple scans of the base table, making it less efficient in both writing and execution.

- GROUPING SETS vs. ROLLUP

ROLLUP is an extension of GROUPING SETS. For example:

```
SELECT a, b, c, SUM(d) FROM tab1 GROUP BY ROLLUP(a, b, c);
```

This ROLLUP is equivalent to the following GROUPING SETS:

```
GROUPING SETS (
 (a, b, c),
 (a, b),
 (a),
 ()
);
```

- GROUPING SETS vs. CUBE

CUBE(a, b, c) is equivalent to the following GROUPING SETS:

```
GROUPING SETS (
 (a, b, c),
 (a, b),
 (a, c),
 (a),
 (b, c),
 (b),
 (c),
 ()
);
```

## APPENDIX

For table creation statements and data files, see the [Window Function](#) appendix.

# Window Function

Analytic functions, also known as window functions, are functions in SQL queries that perform complex calculations on rows in a data set. The characteristic of window functions is that they do not reduce the number of rows in the query result, but instead add a new computed result for each row. Window functions are applicable to various analysis scenarios, such as calculating running totals, rankings, and moving averages.

Below is an example of using a window function to calculate the three-day moving average of sales for each store before and after a given date:

```
CREATE TABLE daily_sales
(store_id INT, sales_date DATE, sales_amount DECIMAL(10, 2))
PROPERTIES (
 "replication_num" = "1"
);
INSERT INTO daily_sales (store_id, sales_date, sales_amount) VALUES (1, '2023-01-01', 100.00), (1, '2023-01-02', 150.00), (1, '2023-01-03', 200.00), (1, '2023-01-04', 250.00), (1, '2023-01-05', 300.00), (1, '2023-01-06', 350.00), (1, '2023-01-07', 400.00), (1, '2023-01-08', 450.00), (1, '2023-01-09', 500.00), (2, '2023-01-01', 110.00), (2, '2023-01-02', 160.00), (2, '2023-01-03', 210.00), (2, '2023-01-04', 260.00), (2, '2023-01-05', 310.00), (2, '2023-01-06', 360.00), (2, '2023-01-07', 410.00), (2, '2023-01-08', 460.00), (2, '2023-01-09', 510.00);

SELECT
 store_id,
 sales_date,
 sales_amount,
 AVG(sales_amount) OVER (PARTITION BY store_id ORDER BY sales_date
 ROWS BETWEEN 3 PRECEDING AND 3 FOLLOWING) AS moving_avg_sales
FROM
 daily_sales;
```

The query result is as follows:

store_id	sales_date	sales_amount	moving_avg_sales
1	2023-01-01	100.00	175.0000
1	2023-01-02	150.00	200.0000
1	2023-01-03	200.00	225.0000
1	2023-01-04	250.00	250.0000
1	2023-01-05	300.00	300.0000
1	2023-01-06	350.00	350.0000
1	2023-01-07	400.00	375.0000
1	2023-01-08	450.00	400.0000
1	2023-01-09	500.00	425.0000
2	2023-01-01	110.00	185.0000
2	2023-01-02	160.00	210.0000
2	2023-01-03	210.00	235.0000
2	2023-01-04	260.00	260.0000
2	2023-01-05	310.00	310.0000
2	2023-01-06	360.00	360.0000
2	2023-01-07	410.00	385.0000
2	2023-01-08	460.00	410.0000
2	2023-01-09	510.00	435.0000

18 rows in set (0.09 sec)

## Introduction to Basic Concepts

### Processing Order

The processing of queries using analytic functions can be divided into three stages.

1. Execute all joins, WHERE, GROUP BY, and HAVING clauses.
2. Provide the result set to the analytic functions and perform all necessary calculations.
3. If the query ends with an ORDER BY clause, process this clause to achieve precise output sorting.

The processing order of the query is illustrated as follows:

processing order

### Result Set Partitioning

Partitions are created after defining groups using the PARTITION BY clause. Analytic functions allow users to divide the query result set into groups of rows called partitions.

#### Note

The term “partition” used in analytic functions is unrelated to the table partitioning feature. In this chapter, the term “partition” refers only to its meaning related to analytic functions.

## Window

For each row in a partition, you can define a sliding data window. This window determines the range of rows involved in performing calculations for the current row. A window has a starting row and an ending row, and depending on its definition, the window can slide at one or both ends. For example, for a cumulative sum function, the starting row is fixed at the first row of its partition, while the ending row slides from the start to the last row of the partition. Conversely, for a moving average, both the start and end points slide.

The size of the window can be set to be as large as all rows in the partition or as small as a sliding window that only includes one row within the partition. It should be noted that when the window is near the boundaries of the partition, due to boundary restrictions, the range of calculations may be reduced, and the function only returns the computed results of the available rows.

When using window functions, the current row is included in the calculation. Therefore, when processing  $n$  items, it should be specified as  $(n-1)$ . For example, if you need to calculate a five-day average, the window should be specified as “rows between 4 preceding and current row,” which can also be abbreviated as “rows 4 preceding.”

## Current Row

Each calculation performed using analytic functions is based on the current row within the partition. The current row serves as the reference point for determining the start and end of the window, as illustrated below.

For instance, a window can be used to define a centered moving average calculation that includes the current row, the 6 rows before the current row, and the 6 rows after the current row. This creates a sliding window containing 13 rows.

Current Row

## Sorting Function

In a sorting function, query results are deterministic only when the specified sorting column is unique; if the sorting column contains duplicate values, the query results may vary each time.

### NTILE Function

NTILE is a window function in SQL used to divide a query result set into a specified number of buckets (groups) and assign a bucket number to each row. This is particularly useful in data analysis and reporting, especially when data needs to be grouped and sorted.

#### 1. Function Syntax

```
NTILE(num_buckets) OVER ([PARTITION BY partition_expression] ORDER BY order_expression)
```

- `num_buckets`: The number of buckets into which to divide the rows.
- `PARTITION BY partition_expression` (optional): Defines how to partition the data.
- `ORDER BY order_expression`: Defines how to sort the data.

#### 2. Using the NTILE Function

Suppose there is a table `class_student_scores` containing students' exam scores, and you want to divide the students into 4 groups based on their scores, with the number of students in each group being as uniform as possible.

First, create the `class_student_scores` table and insert data:

```
CREATE TABLE class_student_scores (
 class_id INT,
 student_id INT,
 student_name VARCHAR(50),
 score INT
)distributed by hash(student_id) properties('replication_num'=1);

INSERT INTO class_student_scores VALUES
(1, 1, 'Alice', 85),
(1, 2, 'Bob', 92),
(1, 3, 'Charlie', 87),
(2, 4, 'David', 78),
(2, 5, 'Eve', 95),
(2, 6, 'Frank', 80),
(2, 7, 'Grace', 90),
(2, 8, 'Hannah', 84);
```

Then, use the NTILE function to divide the students into 4 groups based on their scores:

```
SELECT
 student_id,
 student_name,
 score,
 NTILE(4) OVER (ORDER BY score DESC) AS bucket
```

```
FROM
 class_student_scores;
```

The results are as follows:

student_id	student_name	score	bucket
5	Eve	95	1
2	Bob	92	1
7	Grace	90	2
3	Charlie	87	2
1	Alice	85	3
8	Hannah	84	3
6	Frank	80	4
4	David	78	4

8 rows in set (0.12 sec)

In this example, the `NTILE(4)` function divides the students into 4 groups (buckets) based on their scores, with the number of students in each group being as uniform as possible.

### Notes

- If rows cannot be evenly distributed into buckets, some buckets may have one extra row.
- The `NTILE` function works within each partition. If the `PARTITION BY` clause is used, data within each partition will be separately assigned to buckets.

## 3. Using NTILE with PARTITION BY

Suppose you want to group students by class, and then divide them into 3 groups within each class based on their scores. You can use the `PARTITION BY` and `NTILE` functions:

```
SELECT
 class_id,
 student_id,
 student_name,
 score,
 NTILE(3) OVER (PARTITION BY class_id ORDER BY score DESC) AS bucket
FROM
 class_student_scores;
```

The results are as follows:

class_id	student_id	student_name	score	bucket
1	2	Bob	92	1
1	3	Charlie	87	2
1	1	Alice	85	3
2	5	Eve	95	1
2	7	Grace	90	1
2	8	Hannah	84	2

2	6	Frank	80	2
2	4	David	78	3

8 rows in set (0.05 sec)

In this example, students are partitioned by class, and then within each class, they are divided into 3 groups based on their scores. The number of students in each group is as uniform as possible.

## Analytic Functions

### Using the Analytic Function SUM to Calculate Cumulative Values

Here is an example:

```
SELECT
 i_category,
 year(d_date),
 month(d_date),
 sum(ss_net_paid) as total_sales,
 sum(sum(ss_net_paid)) over(partition by i_category order by year(d_date),month(d_date) ROWS UNBOUNDED
PRECEDING) cum_sales
FROM
 store_sales,
 date_dim d1,
 item
WHERE
 d1.d_date_sk = ss_sold_date_sk
 and i_item_sk = ss_item_sk
 and year(d_date) =2000
 and i_category in ('Books','Electronics')
GROUP BY
 i_category,
 year(d_date),
 month(d_date)
```

The query result is as follows:

i_category	year(d_date)	month(d_date)	total_sales	cum_sales
Books	2000	1	5348482.88	5348482.88
Books	2000	2	4353162.03	9701644.91
Books	2000	3	4466958.01	14168602.92
Books	2000	4	4495802.19	18664405.11
Books	2000	5	4589913.47	23254318.58
Books	2000	6	4384384.00	27638702.58
Books	2000	7	4488018.76	32126721.34
Books	2000	8	9909227.94	42035949.28
Books	2000	9	10366110.30	52402059.58
Books	2000	10	10445320.76	62847380.34
Books	2000	11	15246901.52	78094281.86
Books	2000	12	15526630.11	93620911.97
Electronics	2000	1	5534568.17	5534568.17
Electronics	2000	2	4472655.10	10007223.27
Electronics	2000	3	4316942.60	14324165.87
Electronics	2000	4	4211523.06	18535688.93
Electronics	2000	5	4723661.00	23259349.93
Electronics	2000	6	4127773.06	27387122.99
Electronics	2000	7	4286523.05	31673646.04

Electronics	2000	8	10004890.96	41678537.00
Electronics	2000	9	10143665.77	51822202.77
Electronics	2000	10	10312020.35	62134223.12
Electronics	2000	11	14696000.54	76830223.66
Electronics	2000	12	15344441.52	92174665.18

24 rows in set (0.13 sec)

In this example, the analytic function SUM defines a window for each row, starting from the beginning of the partition (UNBOUNDED PRECEDING) and ending at the current row by default. In this case, nested use of SUM is required because we need to perform SUM on the result that is itself a SUM. Nested aggregation is frequently used in analytic aggregation functions.

## Using the Analytic Function AVG to Calculate Moving Averages

Here is an example:

```
SELECT
 i_category,
 year(d_date),
 month(d_date),
 sum(ss_net_paid) as total_sales,
 avg(sum(ss_net_paid)) over(order by year(d_date),month(d_date) ROWS 2 PRECEDING) avg
FROM
 store_sales,
 date_dim d1,
 item
WHERE
 d1.d_date_sk = ss_sold_date_sk
 and i_item_sk = ss_item_sk
 and year(d_date) =2000
 and i_category='Books'
GROUP BY
 i_category,
 year(d_date),
 month(d_date)
```

The query result is as follows:

i_category	year(d_date)	month(d_date)	total_sales	avg
Books	2000	1	5348482.88	5348482.8800
Books	2000	2	4353162.03	4850822.4550
Books	2000	3	4466958.01	4722867.6400
Books	2000	4	4495802.19	4438640.7433
Books	2000	5	4589913.47	4517557.8900
Books	2000	6	4384384.00	4490033.2200
Books	2000	7	4488018.76	4487438.7433
Books	2000	8	9909227.94	6260543.5666
Books	2000	9	10366110.30	8254452.3333
Books	2000	10	10445320.76	10240219.6666
Books	2000	11	15246901.52	12019444.1933
Books	2000	12	15526630.11	13739617.4633

12 rows in set (0.13 sec)

### Note

In the output data, the AVG column for the first two rows does not calculate a three-day moving average because there are not enough preceding rows for the boundary data (the number of rows specified in SQL is 3).

Additionally, it is possible to calculate window aggregate functions centered on the current row. For instance, this example calculates the centered moving average of monthly sales for products in the “Books” category in the year 2000, specifically averaging the total sales of the month before the current row, the current row, and the month after the current row.

```
SELECT
 i_category,
 YEAR(d_date) AS year,
 MONTH(d_date) AS month,
 SUM(ss_net_paid) AS total_sales,
 AVG(SUM(ss_net_paid)) OVER (ORDER BY YEAR(d_date), MONTH(d_date) ROWS BETWEEN 1 PRECEDING AND 1
 FOLLOWING) AS avg_sales
FROM
 store_sales,
 date_dim d1,
 item
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND YEAR(d_date) = 2000
 AND i_category = 'Books'
GROUP BY
 i_category,
 YEAR(d_date),
 MONTH(d_date)
```

### Note

The centered moving averages for the starting and ending rows in the output data are calculated based on only two days because there are not enough rows before and after the boundary data.

## Reporting Function

A reporting function refers to a scenario where the window range for each row covers the entire Partition. The primary advantage of reporting functions is their ability to pass data multiple times within a single query block, thereby enhancing query performance. For example, queries such as “For each year, find the product category with the highest sales” do not require JOIN operations when using reporting functions. An example is provided below:

```
SELECT year, category, total_sum FROM (
 SELECT
 YEAR(d_date) AS year,
 i_category AS category,
 SUM(ss_net_paid) AS total_sum,
```

```

 MAX(SUM(ss_net_paid)) OVER (PARTITION BY YEAR(d_date)) AS max_sales
FROM
 store_sales,
 date_dim d1,
 item
WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND YEAR(d_date) IN (1998, 1999)
GROUP BY
 YEAR(d_date), i_category
) t
WHERE total_sum = max_sales;

```

The inner query result for reporting `MAX(SUM(ss_net_paid))` is as follows:

```

SELECT year, category, total_sum FROM (
 SELECT
 YEAR(d_date) AS year,
 i_category AS category,
 SUM(ss_net_paid) AS total_sum,
 MAX(SUM(ss_net_paid)) OVER (PARTITION BY YEAR(d_date)) AS max_sales
 FROM
 store_sales,
 date_dim d1,
 item
 WHERE
 d1.d_date_sk = ss_sold_date_sk
 AND i_item_sk = ss_item_sk
 AND YEAR(d_date) IN (1998, 1999)
 GROUP BY
 YEAR(d_date), i_category
) t
WHERE total_sum = max_sales;

```

The complete query result is as follows:

```

+-----+-----+-----+
| year | category | total_sum |
+-----+-----+-----+
| 1998 | Electronics | 91723676.27 |
| 1999 | Electronics | 90310850.54 |
+-----+-----+-----+
2 rows in set (0.12 sec)

```

You can combine reporting aggregation with nested queries to solve some complex problems, such as finding the best-selling products within important product subcategories. For example, to “Find subcategories where product sales account for more than 20% of total sales in their product category, and select the top five products from these subcategories,” the query statement is as follows:

```

SELECT i_category AS categ, i_class AS sub_categ, i_item_id
FROM
 (
 SELECT
 i_item_id, i_class, i_category, SUM(ss_net_paid) AS sales,
 SUM(SUM(ss_net_paid)) OVER (PARTITION BY i_category) AS cat_sales,
 SUM(SUM(ss_net_paid)) OVER (PARTITION BY i_class) AS sub_cat_sales,
 RANK() OVER (PARTITION BY i_class ORDER BY SUM(ss_net_paid)) AS rank_in_line
 FROM

```

```

 store_sales,
 item
 WHERE
 i_item_sk = ss_item_sk
 GROUP BY i_class, i_category, i_item_id
) t
WHERE sub_cat_sales > 0.2 * cat_sales AND rank_in_line <= 5;

```

## LAG / LEAD

The LAG and LEAD functions are suitable for comparisons between values. Both functions can access multiple rows in a table simultaneously without requiring self-joins, thereby enhancing the speed of query processing. Specifically, the LAG function provides access to a row at a given offset before the current row, while the LEAD function provides access to a row at a given offset after the current row.

Below is an example of an SQL query using the LAG function. This query aims to select the total sales for each product category in specific years (1999, 2000, 2001, 2002), the total sales of the previous year, and the difference between them:

```

select year, category, total_sales, before_year_sales, total_sales - before_year_sales from
(
select
 sum(ss_net_paid) as total_sales,
 year(d_date) year,
 i_category category,
 lag(sum(ss_net_paid), 1,0) over(PARTITION BY i_category ORDER BY YEAR(d_date)) AS before_year_sales
from
 store_sales,
 date_dim d1,
 item
where
 d1.d_date_sk = ss_sold_date_sk
 and i_item_sk = ss_item_sk
GROUP BY
 YEAR(d_date), i_category
) t
where year in (1999, 2000, 2001, 2002)

```

The query results are as follows:

year	category	total_sales	before_year_sales	(total_sales - before_year_sales)
1999	Books	88993351.11	91307909.84	-2314558.73
2000	Books	93620911.97	88993351.11	4627560.86
2001	Books	90640097.99	93620911.97	-2980813.98
2002	Books	89585515.90	90640097.99	-1054582.09
1999	Electronics	90310850.54	91723676.27	-1412825.73
2000	Electronics	92174665.18	90310850.54	1863814.64
2001	Electronics	92598527.85	92174665.18	423862.67
2002	Electronics	94303831.84	92598527.85	1705303.99

8 rows in set (0.16 sec)

# Unique Ordering for Analytic Function Data

## 1. Issue of Inconsistent Return Results

When the `ORDER BY` clause of a window function fails to produce a unique ordering of the data, such as when the `ORDER BY` expression results in duplicate values, the order of the rows becomes indeterminate. This means that the return order of these rows may vary across multiple query executions, leading to inconsistent results from the window function.

The following example illustrates how the query returns different results on successive runs. The inconsistency arises primarily because `ORDER BY date_id` does not provide a unique ordering for the `SUM` window function.

```
CREATE TABLE test_window_order
(
 item_id int,
 date_time date,
 sales double
)
distributed BY hash(item_id)
properties("replication_num" = 1);

INSERT INTO test_window_order VALUES
(1, '2024-07-01', 100),
(2, '2024-07-01', 100),
(3, '2024-07-01', 140);

SELECT
 item_id, date_time, sales,
 sum(sales) OVER (ORDER BY date_time ROWS BETWEEN
 UNBOUNDED PRECEDING AND CURRENT ROW) sum
FROM
 test_window_order;
```

Due to duplicate values in the sorting column `date_time`, the following two query results may be observed:

```
+-----+-----+-----+-----+
| item_id | date_time | sales | sum |
+-----+-----+-----+-----+
| 1 | 2024-07-01 | 100 | 100 |
| 3 | 2024-07-01 | 140 | 240 |
| 2 | 2024-07-01 | 100 | 340 |
+-----+-----+-----+-----+
3 rows in set (0.03 sec)
```

## 2. Solution

To address this issue, you can add a unique value column, such as `item_id`, to the `ORDER BY` clause to ensure the uniqueness of the ordering.

```
SELECT
 item_id,
 date_time,
 sales,
 sum(sales) OVER (
 ORDER BY item_id,
 date_time ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) sum
FROM
 test_window_order;
```

This results in a consistent query output:

```
+-----+-----+-----+-----+
| item_id | date_time | sales | sum |
+-----+-----+-----+-----+
| 1 | 2024-07-01 | 100 | 100 |
| 2 | 2024-07-01 | 100 | 200 |
| 3 | 2024-07-01 | 140 | 340 |
+-----+-----+-----+-----+
3 rows in set (0.03 sec)
```

For more information on analytic functions, refer to the Oracle official documentation [SQL for Analysis and Reporting](#)

## Reference

The table creation statement used in the example is as follows:

```
CREATE DATABASE IF NOT EXISTS doc_tpcds;
USE doc_tpcds;

CREATE TABLE IF NOT EXISTS item (
 i_item_sk bigint not null,
 i_item_id char(16) not null,
 i_rec_start_date date,
 i_rec_end_date date,
 i_item_desc varchar(200),
 i_current_price decimal(7,2),
 i_wholesale_cost decimal(7,2),
 i_brand_id integer,
 i_brand char(50),
 i_class_id integer,
 i_class char(50),
 i_category_id integer,
 i_category char(50),
 i_manufact_id integer,
 i_manufact char(50),
 i_size char(20),
 i_formulation char(20),
 i_color char(20),
 i_units char(10),
 i_container char(10),
 i_manager_id integer,
 i_product_name char(50)
)
DUPLICATE KEY(i_item_sk)
DISTRIBUTED BY HASH(i_item_sk) BUCKETS 12
PROPERTIES (
 "replication_num" = "1"
);

CREATE TABLE IF NOT EXISTS store_sales (
 ss_item_sk bigint not null,
 ss_ticket_number bigint not null,
 ss_sold_date_sk bigint,
 ss_sold_time_sk bigint,
 ss_customer_sk bigint,
 ss_cdemo_sk bigint,

```

The data files `item_1_10.dat`, `date_dim_1_10.dat`, `store_sales.csv`, and `customer_address_1_10.dat` can be downloaded by clicking on the [link](#).

# Common Table Expression

---

## Description

Common Table Expression (CTE) define a temporary result set that can be referenced multiple times within the scope of an SQL statement. CTEs are primarily used in SELECT statements.

To specify a CTE, use the WITH clause with one or more comma-separated clauses. Each clause provides a subquery that generates a result set and associates a name with the subquery.

Doris supports nested CTE. Within the statement that contains the WITH clause, you can reference each CTE name to access the corresponding CTE result set. CTE names can be referenced in other CTE, allowing you to define CTE based on other CTE.

Doris **DOES NOT** support recursive CTE. For more information, please read MySQL manual about [recursive CTE](#)

## Example

### Simple CTE

The following example defines CTE named cte1 and cte2 within the WITH clause and refers to them in the top-level SELECT below the WITH clause:

```
WITH
 cte1 AS (SELECT a, b FROM table1),
 cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

### Nested CTE

```
WITH
 cte1 AS (SELECT a, b FROM table1),
 cte2 AS (SELECT c, d FROM cte1)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

### Recursive CTE (NOT Support)

```
```sql WITH r_cte AS ( SELECT 1 AS user_id, 2 as manager_id UNION ALL SELECT user_id, manager_id
FROM r_cte INNER JOIN (SELECT 1 AS user_id, 2 as manager_id) t ON r_cte.manager_id = t.user_id )
SELECT * FROM r_cte
```

Alias Function

Introduction

An alias function refers to assigning an alias name to a function. By registering a new signature for a function or expression fragment in the system, it aims to enhance compatibility or increase convenience.

Alias functions, like other custom functions, support two scopes: LOCAL and GLOBAL.

- **LOCAL:** Alias functions are registered under the current database scope. If the alias function needs to be used under other databases, its fully qualified name should be used, i.e., <Database Name>.<Function Name>.
- **GLOBAL:** Alias functions are registered under the global scope. They can be directly accessed by their function names under any database.

Use Case

Assigning Aliases to Functions

This scenario is common in system migration. When users have existing queries targeting other database systems, there may be functions in these queries that have the same functionality as a function in Doris but different names. In this case, by defining a new alias function for this function, migration can be completed without users noticing any changes.

Simplifying Query Statements

This scenario is often seen in complex analyses. When writing complex query statements, there may be a large number of repetitive expression fragments within a statement or across different statements. By creating an alias function for this complex expression fragment, the query statement can be simplified, enhancing writing convenience and maintainability.

Supported Scope

Expression Requirements

Currently, alias functions require that the root node of the actual expression they point to must be a function expression.

Legal Examples:

```
-- Create an alias function named func with parameters INT, INT, actually pointing to the expression abs(foo + bar);  
CREATE ALIAS FUNCTION func(INT, INT) WITH PARAMETER(foo, bar) AS abs(foo + bar);  
-- Create an alias function named func with parameters DATETIMEV2(3), INT, actually pointing to the  
expression date_trunc(days_sub(foo, bar), 'day')
```

```
CREATE ALIAS FUNCTION func(DATETIMEV2(3), INT) WITH PARAMETER (foo, bar) AS date_trunc(days_sub(foo, bar),  
'day')
```

Illegal Example:

```
-- The root expression is not a function  
CREATE ALIAS FUNCTION func(INT, INT) WITH PARAMETER(foo, bar) AS foo + bar;
```

Parameter Requirements

Currently, alias functions do not support variable-length parameters and must have at least one parameter.

Java UDF, UDAF, UDWF, UDTF

Overview

Java UDF provides a Java interface for users to implement user-defined functions (UDFs) conveniently using the Java programming language. Doris supports the use of Java to develop UDFs, UDAFs, and UDTFs. Unless otherwise specified, “UDF” in the following text refers to all types of user-defined functions.

1. Java UDF: A Java UDF is a commonly used scalar function, where each input row produces a corresponding output row. Common examples include ABS and LENGTH. Notably, Hive UDFs can be directly migrated to Doris, which is convenient for users.
2. Java UDAF: A Java UDAF is a user-defined aggregate function that aggregates multiple input rows into a single output row. Common examples include MIN, MAX, and COUNT.
3. Java UDWF: stands for User-Defined Window Function, which returns a computed value for each row based on a window (one or multiple rows). Common examples include ROW_NUMBER, RANK, and DENSE_RANK.
4. Java UDTF: A Java UDTF is a user-defined table function, where a single input row can generate one or multiple output rows. In Doris, UDTFs must be used with Lateral View to achieve row-to-column transformations. Common examples include EXPLODE and EXPLODE_SPLIT. **Java UDTF is available from version 3.0.0 and onwards.**

Type Correspondence

Type	UDF Argument Type
Bool	Boolean
TinyInt	Byte
SmallInt	Short
Int	Integer
BigInt	Long
LargeInt	BigInteger
Float	Float
Double	Double
Date	LocalDate
Datetime	LocalDateTime
String	String
Decimal	BigDecimal
array<Type>	ArrayList<Type>

Type	UDF Argument Type
map<Type1,Type2>	HashMap<Type1,Type2>
struct<Type...>	ArrayList<Object> (from version 3.0.0)

array/map/struct **types can be nested with other types. For instance, Doris: array<array<int>> corresponds to JAVA UDF Argument Type: ArrayList<ArrayList<Integer>>. Other types follow the same pattern.**

Warning

When creating functions, avoid using varchar in place of string, as this may cause the function to fail.

Usage Notes

1. Complex data types (HLL, Bitmap) are not supported.
2. Users are currently allowed to specify the maximum JVM heap size. The configuration item is the `-Xmx` part of `JAVA_OPTS` in `be.conf`. The default is 1024m. If you need to aggregate data, it is recommended to increase this value to enhance performance and reduce the risk of memory overflow.
3. Due to issues with JVM loading classes with the same name, do not use multiple classes with the same name as UDF implementations simultaneously. If you want to update a UDF with a class of the same name, you need to restart BE to reload the classpath.

Getting Started

This section mainly introduces how to develop a Java UDF. Examples are provided in `samples/doris-demo/java-udf-demo/` for reference. Click [here](#) to view details.

The usage of UDFs is identical to standard functions, with the primary distinction being that built-in functions have a global scope, while UDFs are scoped within the DB.

When the session is linked within the database, directly using the UDF name will search for the corresponding UDF within the current DB. Otherwise, users must explicitly specify the UDF's database name, for example, `dbName.funcName`.

In the following sections, examples will use the table `test_table`. The corresponding table creation script is as follows:

```
CREATE TABLE `test_table` (
  id int NULL,
  d1 double NULL,
  str string NULL
) ENGINE=OLAP
DUPLICATE KEY(`id`)
DISTRIBUTED BY HASH(`id`) BUCKETS 1
PROPERTIES (
```

```
"replication_num" = "1");

insert into test_table values (1, 111.11, "a,b,c");
insert into test_table values (6, 666.66, "d,e");
```

Introduction to Java-UDF Example

When writing a UDF in Java, the main entry point must be the evaluate function. This is consistent with other engines like Hive. In this example, we write an AddOne UDF to perform an increment operation on integer inputs.

1. Write the corresponding Java code and package it into a JAR file.

```
public class AddOne extends UDF {
    public Integer evaluate(Integer value) {
        return value == null ? null : value + 1;
    }
}
```

2. Register and create the Java-UDF function in Doris. For more details on the syntax, refer to [CREATE FUNCTION](#).

```
CREATE FUNCTION java_udf_add_one(int) RETURNS int PROPERTIES (
    "file"="file:///path/to/java-udf-demo-jar-with-dependencies.jar",
    "symbol"="org.apache.doris.udf.AddOne",
    "always_nullable"="true",
    "type"="JAVA_UDF"
);
```

Note

When using `file://`, Doris reads the JAR file on the FE node during `CREATE FUNCTION` to compute the checksum, and reads the JAR file on BE nodes during execution. Therefore, the same JAR file must exist at the same absolute path on all FE and BE nodes, and the file content must be identical. If the file exists only on BE nodes, `CREATE FUNCTION` fails. If the file content differs between FE and BE nodes, execution fails with a checksum mismatch.

3. To utilize UDFs, users must possess the `SELECT` privilege for the corresponding database. And to verify the successful registration of the UDF, you can use the [SHOW FUNCTIONS](#) command.

```
select id,java_udf_add_one(id) from test_table;
+-----+-----+
| id  | java_udf_add_one(id) |
+-----+-----+
| 1   | 2                     |
| 6   | 7                     |
+-----+-----+
```

4. If a UDF is no longer needed, it can be dropped using the following command, as detailed in [DROP FUNCTION](#).

Additionally, if your UDF requires loading large resource files or defining global static variables, you can refer to the method for loading static variables described later in this document.

Introduction to Java-UDAF Example

When writing a UDAF using Java, there are some functions that must be implemented (marked as required) along with an internal class State. The following example will illustrate how to implement them.

1. Write the corresponding Java UDAF code and package it into a JAR file.

**** Example 1: SimpleDemo will implement a simple function similar to sum, where the input parameter is INT and the output parameter is INT.****

```
package org.apache.doris.udf;

import java.io.DataInputStream;
import java.io.DataOutputStream;
import java.io.IOException;
import java.util.logging.Logger;

public class SimpleDemo {

    Logger log = Logger.getLogger("SimpleDemo");

    //Need an inner class to store data
    /*required*/
    public static class State {
        /*some variables if you need */
        public int sum = 0;
    }

    /*required*/
    public State create() {
        /* here could do some init work if needed */
        return new State();
    }

    /*required*/
    public void destroy(State state) {
        /* here could do some destroy work if needed */
    }

    /*Not Required*/
    public void reset(State state) {
        /*if you want this udaf function can work with window function.*/
        /*Must impl this, it will be reset to init state after calculate every window frame*/
        state.sum = 0;
    }

    /*required*/
    //first argument is State, then other types your input
    public void add(State state, Integer val) throws Exception {
        /* here doing update work when input data*/
        if (val != null) {
            state.sum += val;
        }
    }

    /*required*/
    public void serialize(State state, DataOutputStream out) throws Exception {
        /* serialize some data into buffer */
    }
}
```

```

        out.writeInt(state.sum);
    }

    /**required*/
    public void deserialize(State state, DataInputStream in) throws Exception {
        /* deserialize get data from buffer before you put */
        int val = in.readInt();
        state.sum = val;
    }

    /**required*/
    public void merge(State state, State rhs) throws Exception {
        /* merge data from state */
        state.sum += rhs.sum;
    }

    /**required*/
    //return Type you defined
    public Integer getValue(State state) throws Exception {
        /* return finally result */
        return state.sum;
    }
}

```

**** Example 2: MedianUDAF is a function that calculates the median. The input types are (DOUBLE, INT), and the output type is DOUBLE. ****

```

package org.apache.doris.udf.demo;

import java.io.DataInputStream;
import java.io.DataOutputStream;
import java.io.IOException;
import java.math.BigDecimal;
import java.util.Arrays;
import java.util.logging.Logger;

/* UDAF to calculate the median */
public class MedianUDAF {
    Logger log = Logger.getLogger("MedianUDAF");

    // State storage
    public static class State {
        // Precision of the return result
        int scale = 0;
        // Whether it is the first time to execute the add method for a certain aggregation condition under a
        certain tablet
        boolean isFirst = true;
        // Data storage
        public StringBuilder stringBuilder;
    }

    // Initialize the state
    public State create() {
        State state = new State();
        // Pre-initialize based on the amount of data that needs to be aggregated under each aggregation
        condition of each tablet to increase performance
        state.stringBuilder = new StringBuilder(1000);
        return state;
    }

    // Process each data under respective aggregation conditions for each tablet
    public void add(State state, Double val, int scale) {
        if (val != null && state.isFirst) {

```

```

        state.stringBuilder.append(scale).append(",").append(val).append(",");
        state.isFirst = false;
    } else if (val != null) {
        state.stringBuilder.append(val).append(",");
    }
}

// Data needs to be output for aggregation after processing
public void serialize(State state, DataOutputStream out) throws IOException {
    // Currently, only DataOutputStream is provided. If serialization of objects is required, methods
    such as concatenating strings, converting to JSON, or serializing into byte arrays can be considered
    // If the State object needs to be serialized, it may be necessary to implement a serialization
    interface for the State inner class
    // Ultimately, everything needs to be transmitted via DataOutputStream
    out.writeUTF(state.stringBuilder.toString());
}

// Obtain the output data from the data processing execution unit
public void deserialize(State state, DataInputStream in) throws IOException {
    String string = in.readUTF();
    state.scale = Integer.parseInt(String.valueOf(string.charAt(0)));
    StringBuilder stringBuilder = new StringBuilder(string.substring(2));
    state.stringBuilder = stringBuilder;
}

// The aggregation execution unit merges the processing results of data under certain aggregation
conditions for a given key. The state1 parameter is the initialized instance during the first merge of each
key
public void merge(State state1, State state2) {
    state1.scale = state2.scale;
    state1.stringBuilder.append(state2.stringBuilder.toString());
}

// Output the final result after merging the data for each key
public Double getValue(State state) {
    String[] strings = state.stringBuilder.toString().split(",");
    double[] doubles = new double[strings.length];
    for (int i = 0; i < strings.length - 1; i++) {
        doubles[i] = Double.parseDouble(strings[i + 1]);
    }

    Arrays.sort(doubles);
    double n = doubles.length;
    if (n == 0) {
        return 0.0;
    }
    double index = (n - 1) / 2.0;

    int low = (int) Math.floor(index);
    int high = (int) Math.ceil(index);

    double value = low == high ? (doubles[low] + doubles[high]) / 2 : doubles[high];

    BigDecimal decimal = new BigDecimal(value);
    return decimal.setScale(state.scale, BigDecimal.ROUND_HALF_UP).doubleValue();
}

// Executed after each execution unit completes
public void destroy(State state) {
}
}

```

2. Register and create the Java-UDAF function in Doris. For more syntax details, please refer to [CREATE FUNCTION](#).

```
CREATE AGGREGATE FUNCTION simple_demo(INT) RETURNS INT PROPERTIES (
  "file"="file:///pathTo/java-udaf.jar",
  "symbol"="org.apache.doris.udf.SimpleDemo",
  "always_nullable"="true",
  "type"="JAVA_UDF"
);
```

3. When using Java-UDAF, you can perform aggregation either by grouping or by aggregating all results:

```
select simple_demo(id) from test_table group by id;
+-----+
| simple_demo(id) |
+-----+
|          1      |
|          6      |
+-----+
```

```
select simple_demo(id) from test_table;
+-----+
| simple_demo(id) |
+-----+
|          7      |
+-----+
```

Introduction to Java-UDWF Example

1. The implementation is similar to Java UDAF, but requires an additional `reset()` method to clear the state.

```
void reset(State state)
```

2. Register and create the Java-UDWF function same as UDAF in Doris. For more syntax details, please refer to [CREATE FUNCTION](#).

```
CREATE AGGREGATE FUNCTION simple_demo_window(INT) RETURNS INT PROPERTIES (
  "file"="file:///pathTo/java-udaf.jar",
  "symbol"="org.apache.doris.udf.SimpleDemo",
  "always_nullable"="true",
  "type"="JAVA_UDF"
);
```

3. Java UDWF allows querying computed results within specific window frames. For detailed syntax, refer to [Window Function](#)

```
select id, simple_demo_window(id) over(partition by id order by d1 rows between 1 preceding and 1
following) as res from test_table;
+-----+-----+
| id  | res |
+-----+-----+
| 1   | 1   |
| 6   | 6   |
+-----+-----+
```

Introduction to Java-UDTF Example

UDTF is supported starting from Doris version 3.0.

Best Practices

Loading static variables

Currently, in Doris, executing a UDF function, e.g., `select udf(col) from table`, will load the `udf.jar` package for each concurrent instance, and unload the `udf.jar` package when the instance finish.

If the `udf.jar` file needs to load a file of several hundred MBs, the memory usage will increase sharply due to concurrency, potentially leading to OOM (Out of Memory).

Alternatively, if you want to use a connection pool, this approach will not allow you to initialize it only once in the static area.

Here are two solutions, with the second solution requiring Doris version branch-3.0 or above.

Solution 1:

The solution is to split the resource loading code, generate a separate jar package, and have other packages directly reference this resource jar package.

Assume the files have been split into `DictLibrary` and `FunctionUdfAR`.

```
public class DictLibrary {
    private static HashMap<String, String> res = new HashMap<>();

    static {
        // suppose we built this dictionary from a certain local file.
        res.put("key1", "value1");
        res.put("key2", "value2");
        res.put("key3", "value3");
        res.put("0", "value4");
        res.put("1", "value5");
        res.put("2", "value6");
    }

    public static String evaluate(String key) {
        if (key == null) {
            return null;
        }
        return res.get(key);
    }
}
```

```
public class FunctionUdf {
    public String evaluate(String key) {
        String value = DictLibrary.evaluate(key);
        return value;
    }
}
```

1. Compile the DictLibrary file separately to generate an independent jar package, resulting in a resource file DictLibrary.jar:

```
javac ./DictLibrary.java
jar -cf ./DictLibrary.jar ./DictLibrary.class
```

2. Then compile the FunctionUdf file, directly referencing the resource package from the previous step, resulting in the FunctionUdf.jar package:

```
javac -cp ./DictLibrary.jar ./FunctionUdf.java
jar -cvf ./FunctionUdf.jar ./FunctionUdf.class
```

3. After the above two steps, you will get two jar packages. To allow the resource jar package to be referenced by all concurrent instances, place it in the deployment path be/custom_lib. After the restarting, it will be loaded with the JVM startup. As a result, the resources will be loaded when the service starts and released when the service stops.

4. Finally, use the create function statement to create a UDF function

```
CREATE FUNCTION java_udf_dict(string) RETURNS string PROPERTIES (
  "file"="file:///pathTo/FunctionUdf.jar",
  "symbol"="org.apache.doris.udf.FunctionUdf",
  "always_nullable"="true",
  "type"="JAVA_UDF"
);
```

Solution 2:

The BE (Backend) globally caches the JAR file and customizes the expiration and eviction time. When creating a function, two additional properties are added:

static_load: This defines whether to use the static cache loading method. **expiration_time:** This defines the expiration time of the JAR file, in minutes. If the static cache loading method is used, the UDF instance will be cached after the first call and initialization. On subsequent calls to the UDF, the system will first search in the cache. If not found, the initialization process will be triggered.

Additionally, a background thread regularly checks the cache. If the function has not been called within the configured expiration time, it will be evicted from the cache. If the function is called, the cache timestamp will be automatically updated.

```
public class Print extends UDF {
    static Integer val = 0;
    public Integer evaluate() {
        val = val + 1;
        return val;
    }
}
```

```
CREATE FUNCTION print_12() RETURNS int
PROPERTIES (
  "file" = "file:///path/to/java-udf-demo-jar-with-dependencies.jar",
  "symbol" = "org.apache.doris.udf.Print",
```

```
"always_nullable"="true",
"type" = "JAVA_UDF",
"static_load" = "true", // default value is false
"expiration_time" = "60" // default value is 360 minutes
);
```

As we can see, the result keeps incrementing, which proves that the loaded JAR file is not being unloaded and reloaded. Instead, the variables are being re-initialized to 0.

```
mysql [test_query_qa]>select print_12();
+-----+
| print_12() |
+-----+
|          1 |
+-----+
1 row in set (0.40 sec)

mysql [test_query_qa]>select print_12();
+-----+
| print_12() |
+-----+
|          2 |
+-----+
1 row in set (0.03 sec)

mysql [test_query_qa]>select print_12();
+-----+
| print_12() |
+-----+
|          3 |
+-----+
1 row in set (0.04 sec)
```

Complex Type

Doris supports complex types such as Array, Map, Struct, and JSON.

Doris provides various functions specifically designed for these complex types.

For detailed information on the supported functions, please refer to the [SQL manual - Array functions](#), [SQL manual - Map functions](#) data type, [SQL manual - Struct functions](#), and [SQL manual - Json functions](#).

Column to Row (Lateral View)

Column to Row (Lateral View)

Used in conjunction with generator functions such as EXPLODE, will generate a virtual table containing one or more rows. LATERAL VIEW applies rows to each raw input row.

Grammar

```
LATERAL VIEW generator_function ( expression [, ...] ) table_identifier AS column_identifier [, ...]
```

Parameters

- generator_function

Generator functions (EXPLODE, EXPLODE_SPLIT, etc.).

- table_identifier

Alias for generator_function.

- column_identifier

List column alias generator_function, which can be used to reference the output columns. The number of column identifiers must match the number of columns returned by the generator function.

Example

```
CREATE TABLE `person` (  
  `id` int(11) NULL,  
  `name` text NULL,  
  `age` int(11) NULL,  
  `class` int(11) NULL,  
  `address` text NULL  
) ENGINE=OLAP  
UNIQUE KEY(`id`)  
COMMENT 'OLAP'  
DISTRIBUTED BY HASH(`id`) BUCKETS 1  
PROPERTIES (  
  "replication_allocation" = "tag.location.default: 1",  
  "in_memory" = "false",  
  "storage_format" = "V2",  
  "disable_auto_compaction" = "false"  
);  
  
INSERT INTO person VALUES  
  (100, 'John', 30, 1, 'Street 1'),  
  (200, 'Mary', NULL, 1, 'Street 2'),  
  (300, 'Mike', 80, 3, 'Street 3'),  
  (400, 'Dan', 50, 4, 'Street 4');
```

```
mysql> SELECT * FROM person
->      LATERAL VIEW EXPLODE(ARRAY(30, 60)) tableName AS c_age;
```

id	name	age	class	address	c_age
100	John	30	1	Street 1	30
100	John	30	1	Street 1	60
200	Mary	NULL	1	Street 2	30
200	Mary	NULL	1	Street 2	60
300	Mike	80	3	Street 3	30
300	Mike	80	3	Street 3	60
400	Dan	50	4	Street 4	30
400	Dan	50	4	Street 4	60

8 rows in set (0.12 sec)

Tuning Overview

Query performance tuning is a systematic process that requires multi-level and multi-dimensional adjustments to the database system. Below is an overview of the tuning process and methodology:

1. Firstly, business personnel and database administrators (DBAs) need to have a comprehensive understanding of the database system being used, including the hardware utilized by the business system, the scale of the cluster, the version of the database software being used, as well as the features provided by the specific software version.
2. Secondly, an effective performance diagnostic tool is a necessary prerequisite for identifying performance issues. Only by efficiently and quickly locating problematic SQL queries or slow SQL queries can subsequent specific performance tuning processes be carried out.
3. After entering the performance tuning phase, a range of commonly used performance analysis tools are indispensable. These include specialized tools provided by the currently running database system, as well as general tools at the operating system level.
4. With these tools in place, specialized tools can be used to obtain detailed information about SQL queries running on the current database system, aiding in the identification of performance bottlenecks. Meanwhile, general tools can serve as auxiliary analysis methods to assist in locating issues.

In summary, performance tuning requires evaluating the current system's performance status from a holistic perspective. Firstly, it is necessary to identify business SQL queries with performance issues, then utilize analysis tools to discover performance bottlenecks, and finally implement specific tuning operations.

Based on the aforementioned tuning process and methodology, Apache Doris provides corresponding tools at each of these levels. The following sections will introduce the performance [diagnostic tools](#), [analysis tools](#), and [tuning process](#) respectively.

Overview

Currently, Doris considers SQL queries with execution times exceeding 5 seconds as slow SQL by default. This threshold can be configured via `config.qe_slow_log_ms`. Doris currently offers the following three diagnostic channels to help quickly identify slow SQL queries with performance issues:

The log module in Doris Manager provides a slow SQL filtering function. Users can view slow SQL by selecting the `fe.audit.log` on a specific FE node. By simply entering `slow_query` in the search box, the historical slow SQL information of the current system will be displayed on the page, as shown in the figure below:

Doris Manager Monitoring and Logging

Currently, Doris FE provides four types of Audit Logs, including `slow_query`, `query`, `load`, and `stream_load`. Besides accessing the logs through the log page on the cluster where the Manager service is installed and deployed, Audit Logs can also be directly obtained by accessing the `fe/log/fe.audit.log` file on the node where FE is located.

By directly searching for the `slow_query` tag in `fe.audit.log`, you can quickly filter out slow-executing SQL queries, as shown below:

```
2024-07-18 11:23:13,042 [slow_query]
|Client=127.0.0.1:63510|User=root|Ctl=internal|Db=tpch_sf1000|State=E0F|ErrorCode=0|ErrorMessage=|Time(ms)=11603|ScanBytes=236667379712|ScanRows=13649979418|ReturnRows=100|StmtId=1689|QueryId=91ff336304f14182-9ca537eee75b3856|IsQuery=true|isNereids=true|feIp=172.21.0.10|Stmt=select      c_name,      c_custkey,

```

The slow SQL obtained through `fe.audit.log` allows users to easily access detailed information such as execution time, number of rows scanned, number of rows returned, and the SQL statement itself, laying the foundation for further reproducing and locating performance issues.

Additionally, the Audit Log includes a `SqlDigest` field (e.g., `SqlDigest=...` in the example above). This field is a hash value generated from the structure of the SQL statement (with specific parameter values removed). By aggregating and analyzing `SqlDigest` in `slow_query`, you can identify “patterns” of slow queries. This means that even if specific SQL statements differ slightly due to parameters, their `SqlDigest` will be identical as long as the structure is the same.

Using `SqlDigest`, users can determine which SQL patterns appear most frequently or consume the most time, allowing them to prioritize optimization for these “high-frequency” or “high-latency” patterns. This approach significantly improves the efficiency of slow query optimization by avoiding the inefficiency of analyzing individual SQL statements one by one.

It is important to note that `SqlDigest` itself is just a hash value and is not directly readable. Once the slow query pattern to be optimized is identified, you need to refer to the `Stmt` field in the Audit Log to get the specific SQL statement content corresponding to that pattern. Furthermore, the `QueryId` field can be used to retrieve detailed Profile information for the query (Profile retrieval and analysis will be detailed in subsequent sections) for in-depth performance analysis and optimization.

Slow Query Analysis Example

Taking the 4 slow query logs in the `fe.audit.log` above as an example, we can observe:

1. The first log (`Time(ms)=11603`) has a `SqlDigest` of `f23c7a7ecff61da33f537b2699e9b053`.
2. The subsequent three logs (`Time(ms)=8978, 8514, 8660`) all have the `SqlDigest` of `fec5a7136f9375aa968a4de971b994da`.

This indicates that the latter three slow queries belong to the same SQL pattern (structurally identical), although their specific execution times (`Time(ms)`) and details differ slightly.

In real-world optimization scenarios, if we find that a certain `SqlDigest` (such as `fec5a7136f9375aa968a4de971b994da`) appears repeatedly in the slow query logs, or accounts for a high proportion of the total execution time, we should prioritize optimizing this pattern.

Recommended Optimization Steps:

1. **Identify Business Logic:** By examining the `Stmt` field in any log entry of this pattern:

```
select      s_name,      count(*) as numwait from      supplier,      lineitem l1,      orders,      nation
where ...
```

We can identify the specific SQL logic.

2. **Deep Analysis:** Use the `QueryId` (e.g., `6e1fae453cb04d9a-b1e5f94d9cea1885`) from the log to retrieve the corresponding Query Profile in Doris. The Profile helps analyze whether the issue is due to excessive data scanning, prolonged Join operations, or other reasons, enabling targeted optimization strategies (such as adding indexes, optimizing SQL writing, or adjusting table structures).

Once the issue with this pattern is resolved, all slow queries belonging to this pattern will be improved.

audit_log System Table

Starting from Doris version 2.1, the audit_log system table is provided under the __internal_schema database for users to view the execution status of SQL queries. Before using it, the global configuration set `global enable_audit_plugin=true`; needs to be enabled (this switch is disabled by default).

```
mysql> use __internal_schema;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
mysql> show tables;
+-----+
| Tables_in__internal_schema |
+-----+
| audit_log                   |
| column_statistics           |
| histogram_statistics        |
| partition_statistics        |
+-----+
4 rows in set (0.00 sec)

mysql> desc audit_log;
+-----+-----+-----+-----+-----+-----+
| Field          | Type          | Null | Key  | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| query_id       | varchar(48)   | Yes  | true | NULL    |       |
| time           | datetime      | Yes  | true | NULL    |       |

| stmt          | text          | Yes  | false| NULL    | NONE  |
+-----+-----+-----+-----+-----+-----+
```

Through the audit_log internal table, users can query detailed SQL execution information and perform detailed statistical analysis such as slow query filtering.

Summary

Doris Manager logs, audit logs, and the audit_log system table provide capabilities such as automatic or manual filtering of slow SQL queries, as well as fine-grained statistical analysis of SQL execution information. These tools offer powerful support for systematic performance diagnosis and tuning.

Analysis Tools

Overview

The previous section on [diagnostic tools](#) helped business and operations personnel pinpoint specific slow SQL queries. This section will introduce how to analyze the performance bottlenecks of slow SQL to determine which part of the SQL execution process is causing the slowdown.

The execution process of an SQL query can be roughly divided into two stages: plan generation and plan execution. The former is responsible for generating the execution plan, while the latter executes the specific plan. Issues in either part can lead to performance bottlenecks. For example, if a poor plan is generated, no matter how excellent the executor is, good performance cannot be achieved. Similarly, even with a correct plan, inappropriate execution methods can also lead to performance bottlenecks. Furthermore, the performance of the executor is closely related to the current hardware and system architecture. Deficiencies in infrastructure or incorrect configurations can also cause performance issues.

All three types of problems require the support of good analysis tools. Based on this, the Doris system provides two performance analysis tools to analyze bottlenecks in planning and execution respectively. Additionally, the system level also offers corresponding performance monitoring tools to assist in locating performance bottlenecks. The following sections will introduce these three aspects:

Doris Explain

An execution plan describes the specific execution method and process of an SQL query. For example, for an SQL query that joins two tables, the execution plan will show information such as how the tables are accessed, the join method, and the join order.

Doris provides the Explain tool, which conveniently displays detailed information about an SQL query's execution plan. By analyzing the plan output by Explain, users can quickly locate bottlenecks at the planning level and perform plan-level tuning based on different situations.

Doris offers multiple Explain tools with different levels of granularity, such as Explain Verbose, Explain All Plan, Explain Memo Plan, and Explain Shape Plan, which are used to display the final physical plan, logical plans at various stages, plans based on cost optimization processes, and plan shapes, respectively. For detailed information, please refer to the Execution Plan Explain section to learn about the usage of various Explain tools and the interpretation of their output information.

By analyzing the output of Explain, business personnel and DBAs can quickly locate performance bottlenecks in the current plan. For example, by analyzing the execution plan, it may be discovered that filters are not pushed down to the base tables, resulting in data not being filtered early and an excessive amount of data being involved in calculations, leading to performance issues. Another example is that in an Inner equi-join of two tables, the filter conditions on one side of the join condition are not derived to the other side, resulting in the data of the other table not being filtered early, which may also lead to suboptimal performance. Such performance bottlenecks can be located and resolved by analyzing the output of Explain.

For cases of using Doris Explain output to perform plan-level tuning, please refer to the [Plan Tuning](#) section.

Doris Profile

The Explain tool described above outlines the execution plan for an SQL query, such as planning a join operation between tables t1 and t2 as a Hash Join, with t1 designated as the build side and t2 as the probe side. When the SQL query is actually executed, understanding how much time each specific execution step takes—for instance, how long the build phase lasts and how long the probe phase lasts—is crucial for performance analysis and tuning. The Profile tool provides detailed execution information for this purpose. The following section first gives an overview of the Profile file structure and then introduces the meanings of execution times in Merged Profile, Execution Profile, and PipelineTask.

Profile File Structure

A Profile file contains several main sections:

1. Basic query information: including ID, time, database, etc.
2. The SQL statement and its execution plan.
3. Time spent by the Frontend (FE) on tasks like Plan Time, Schedule Time, etc.
4. Execution time spent by each operator during the Backend (BE) processing (including Merged Profile and Execution Profile).
5. The detailed information about the execution side is mainly contained in the last part. Next, we will mainly introduce what information the Profile can provide for performance analysis.

Merged Profile

To help users more accurately analyze performance bottlenecks, Doris provides aggregated profile results for each operator. Taking the EXCHANGE_OPERATOR as an example:

```
EXCHANGE_OPERATOR (id=4):
- BlocksProduced: sum 0, avg 0, max 0, min 0
- CloseTime: avg 34.133us, max 38.287us, min 29.979us
- ExecTime: avg 700.357us, max 706.351us, min 694.364us
- InitTime: avg 648.104us, max 648.604us, min 647.605us
- MemoryUsage: sum , avg , max , min
- PeakMemoryUsage: sum 0.00 , avg 0.00 , max 0.00 , min 0.00
- OpenTime: avg 4.541us, max 5.943us, min 3.139us
- ProjectionTime: avg 0ns, max 0ns, min 0ns
- RowsProduced: sum 0, avg 0, max 0, min 0
- WaitForDependencyTime: avg 0ns, max 0ns, min 0ns
- WaitForData0: avg 9.434ms, max 9.476ms, min 9.391ms
```

The Merged Profile consolidates key metrics for each operator, with the core metrics and their meanings outlined below:

Metric Name	Metric Definition
BlocksProduced	Number of Data Blocks produced
CloseTime	Time spent by the Operator during the close phase
ExecTime	Total execution time of the Operator across all phases

Metric Name	Metric Definition
InitTime	Time spent by the Operator during the initialization phase
MemoryUsage	Memory usage of the Operator during execution
OpenTime	Time spent by the Operator during the open phase
ProjectionTime	Time spent by the Operator on projections
RowsProduced	Number of rows returned by the Operator
WaitForDependencyTime	Time the Operator waits for its execution dependencies

In Doris, each operator executes concurrently based on the concurrency level set by the user. Therefore, the Merged Profile calculates the Max, Avg, and Min values for each metric across all concurrent executions.

WaitForDependencyTime varies for each Operator, as the execution dependencies differ. For instance, in the case of an EXCHANGE_OPERATOR, the dependency is on data being sent by upstream operators via RPC. Thus, WaitForDependencyTime in this context specifically refers to the time spent waiting for upstream operators to send data.

Execution Profile

Unlike the Merged Profile, the Execution Profile displays detailed metrics for a specific concurrent execution. Taking the exchange operator with id=4 as an example:

```
EXCHANGE_OPERATOR (id=4):(ExecTime: 706.351us)
  - BlocksProduced: 0
  - CloseTime: 38.287us
  - DataArrivalWaitTime: 0ns
  - DecompressBytes: 0.00
  - DecompressTime: 0ns
  - DeserializeRowBatchTimer: 0ns
  - ExecTime: 706.351us
  - FirstBatchArrivalWaitTime: 0ns
  - InitTime: 647.605us
  - LocalBytesReceived: 0.00
  - MemoryUsage:
  - PeakMemoryUsage: 0.00
  - OpenTime: 5.943us
  - ProjectionTime: 0ns
  - RemoteBytesReceived: 0.00
  - RowsProduced: 0
  - SendersBlockedTotalTimer(*): 0ns
  - WaitForDependencyTime: 0ns
  - WaitForData0: 9.476ms
```

In this profile, for instance, LocalBytesReceived is a metric specific to the exchange operator and not found in other operators, hence it is not included in the Merged Profile.

PipelineTask Execution Time

In Doris, a PipelineTask consists of multiple operators. When analyzing the execution time of a PipelineTask, several key aspects need to be focused on: 1. ExecuteTime: The actual execution time of the entire PipelineTask, which is approximately equal to the sum of the ExecTime of all operators in this task 2.

WaitWorkerTime: The time that a task waits for a worker to execute. When a task is in the runnable state, it has to wait for an idle worker to execute it. The time it takes depends mainly on the cluster load. 3. Waiting time for executing dependencies: A task can be executed only when all the dependencies of each operator meet the execution conditions, and the time a task waits for executing dependencies is the sum of the waiting times of these dependencies. For example, simplifying one of the tasks in this example:

```
```sql
PipelineTask (index=1):(ExecTime: 4.773ms)
- ExecuteTime: 1.656ms
 - CloseTime: 90.402us
 - GetBlockTime: 11.235us
 - OpenTime: 1.448ms
 - PrepareTime: 1.555ms
 - SinkTime: 14.228us
- WaitWorkerTime: 63.868us
 DATA_STREAM_SINK_OPERATOR (id=8,dst_id=8):(ExecTime: 1.688ms)
 - WaitForDependencyTime: 0ns
 - WaitForBroadcastBuffer: 0ns
 - WaitForRpcBufferQueue: 0ns
 AGGREGATION_OPERATOR (id=7 , nereids_id=648):(ExecTime: 398.12us)
 - WaitForDependency[AGGREGATION_OPERATOR_DEPENDENCY]Time: 10.495ms
```
```

This task includes two operators (DATA_STREAM_SINK_OPERATOR - AGGREGATION_OPERATOR), of which DATA_STREAM_SINK_OPERATOR has two dependencies (WaitForBroadcastBuffer and WaitForRpcBufferQueue), and AGGREGATION_OPERATOR has one dependency (AGGREGATION_OPERATOR_DEPENDENCY), so the time consumption of the current task is distributed as follows:

1. ExecuteTime: 1.656ms (The actual execution time of the entire PipelineTask, which is approximately the sum of the ExecTime of all operators within the task).
2. WaitWorkerTime: 63.868us (The time the task waits for an execution worker. When the task is in a runnable state, it waits for an available worker to execute it, and this duration primarily depends on the cluster load).
3. Time Waiting for Execution Dependencies: 10.495ms (WaitForBroadcastBuffer + WaitForRpcBufferQueue + WaitForDependency[AGGREGATION_OPERATOR_DEPENDENCY]Time). The time a task waits for execution dependencies is the sum of the waiting times for these dependencies.

For cases of using Profile for execution-level tuning, please refer to the [Tuning Execution](#) section.

System-Level Performance Tools

Commonly used system tools can assist in identifying performance bottlenecks during execution. For instance, widely used Linux tools such as top, free, perf, sar, and iostat can be utilized to observe the CPU, memory, I/O, and network status of the system while SQL is running, thereby aiding in the identification of performance bottlenecks.

Summary

Effective performance analysis tools are crucial for quickly identifying performance bottlenecks. Doris provides Explain and Profile, offering powerful support for analyzing issues with execution plans and identifying which operations consume the most time during execution. Additionally, proficient use of system-level analysis tools can greatly assist in locating performance bottlenecks.

Tuning Process

Overview

Performance tuning is a systematic process that requires a comprehensive methodology and implementation framework for systematic diagnosis and optimization. With the strong support of [diagnostic tools](#) and [analysis tools](#), the Doris system can efficiently diagnose, analyze, locate, and resolve performance issues. The complete four-step process for tuning is as follows:

Tuning process

Step 1: Use Performance Diagnostic Tools to Identify Slow Queries

For business systems running on Doris, use the aforementioned [performance diagnostic tools](#) to identify slow SQL queries.

- If Doris Manager is installed, it is recommended to use the Manager's log page for convenient visual identification of slow queries.
- If Manager is not installed, you can directly check the `fe.audit.log` file on the FE node or the `audit_log` system table to obtain a list of slow SQL queries and prioritize them for tuning.

Step 2: Schema Design and Tuning

After identifying specific slow SQL queries, the first priority is to inspect and tune the business schema design to eliminate performance issues caused by unreasonable schema design.

Schema design tuning can be divided into three aspects:

- [Table-level Schema Design Tuning](#), such as adjusting the number of partitions and buckets, and field optimization;
- [Index Design and Tuning](#)
- The use of specific optimization techniques, such as [Optimizing Join with Colocate Group](#). The main goal is to eliminate performance issues caused by unreasonable schema design or failure to fully leverage Doris's existing optimization capabilities.

For detailed tuning examples, please refer to the documentation on [Plan Tuning](#).

Step 3: Plan Tuning

After inspecting and tuning the business schema, the main task of tuning begins: plan tuning and execution tuning. As mentioned above, at this stage, the primary task is to make full use of the various levels of Explain tools provided by Doris to systematically analyze the execution plans of slow SQL queries and identify key optimization points for targeted optimization.

- For single-table query and analysis scenarios, you can analyze the execution plan to check if [partition pruning](#) is working properly and [use single-table materialized views for query acceleration](#).
- For complex multi-table analysis scenarios, you can analyze the Join Order to determine if it is reasonable and identify specific performance bottlenecks. You can also [use multi-table materialized views for transparent rewriting to accelerate queries](#). If unexpected situations occur, such as unreasonable Join Order, you can manually specify the Join Hint to bind the execution plan, such as [using the Leading hint to control Join Order](#), [using the Shuffle Hint to adjust the Join shuffle method](#), and [using Hints to control cost-based optimization rules](#), to achieve the goal of tuning the execution plan.
- For specific scenarios, you can also leverage advanced features provided by Doris, such as [using SQL Cache to accelerate queries](#).

For detailed tuning examples, please refer to the documentation on [Plan Tuning](#).

Step 4: Execution Tuning

In the execution tuning stage, you need to validate the effectiveness of plan tuning based on the actual execution of SQL queries. Additionally, within the framework of the existing plan, continue to analyze bottlenecks on the execution side, identify which execution stages are slow, or other common issues such as suboptimal parallelism.

Taking multi-table analysis queries as an example, you can analyze the Profile to check if the planned Join order is reasonable, if Runtime Filters are effective, and if the parallelism meets expectations. Furthermore, the Profile can provide feedback on machine load, such as slow I/O or unexpected network transmission performance. When confirming and diagnosing such issues, system-level tools are needed to assist in diagnosis and tuning.

For detailed tuning examples, please refer to the documentation on [Execution Tuning](#).

When analyzing specific performance issues, it is recommended to first check the plan and then tune the execution. Start by using the Explain tool to confirm the execution plan, and then use the Profile tool to locate and tune execution performance. Reversing the order may lead to inefficiencies and hinder the rapid identification of performance issues.

Summary

Query tuning is a systematic process, and Doris provides users with tools across various dimensions to facilitate the diagnosis, identification, analysis, and resolution of performance issues at different levels. By familiarizing themselves with these diagnostic and analysis tools and adopting reasonable tuning methods, business personnel and DBAs can quickly and effectively address performance bottlenecks, better unleash Doris's powerful performance advantages, and better adapt to business scenarios for business enablement.

Materialized View Overview

Materialized views are entities that contain both computation logic and data. Unlike views, which only contain computation logic and do not store data themselves, materialized views do.

Use Cases for Materialized Views

Materialized views calculate and store data based on SQL definitions and update periodically or in real-time according to policies. They can be queried directly or used for transparent query rewriting. They are applicable in the following scenarios:

Query Acceleration

In decision support systems, such as BI reports and ad-hoc queries, these analytical queries often involve aggregation operations and may include multi-table joins. Since calculating the results of such queries can be resource-intensive and response times may reach minutes, while business scenarios often require second-level responses, materialized views can be constructed to accelerate common queries.

Lightweight ETL (Data Modeling)

In data layering scenarios, nested materialized views can be used to construct DWD and DWM layers, leveraging the scheduling and refresh capabilities of materialized views.

Lakehouse Integration

For multiple external data sources, materialized views can be constructed for the tables used by these data sources to save costs from importing external tables to internal tables and accelerate the query process.

Classification of Materialized Views

Classified by Data Timeliness: Synchronous vs Asynchronous

- Synchronous materialized views need to maintain strong consistency with the base table data.
- Asynchronous materialized views maintain eventual consistency with the base table data and may have some delay. They are typically used in scenarios where data timeliness is not critical, often using T+1 or hourly data to construct materialized views. If high timeliness is required, consider using synchronous materialized views.

Currently, synchronous materialized views do not support direct queries, while asynchronous materialized views do.

Classified by SQL Mode Supporting Transparent Rewriting: Single Table vs Multi-Table

The SQL definition of a materialized view can include single-table queries or multi-table queries. From the perspective of the number of tables used, materialized views can be classified as single-table or multi-table

materialized views.

- For asynchronous materialized views, both single-table and multi-table can be used.
- For synchronous materialized views, only single-table can be used.

Classified by Materialized View Refresh: Full Refresh vs Partition Incremental Refresh vs Real-Time Refresh

For Asynchronous Materialized Views

- Full Refresh: Computes all data of the materialized view's SQL definition.
- Partition Incremental Refresh: When the partition data of the base table of the materialized view changes, it identifies the partitions of the materialized view that correspond to the changes and only refreshes those partitions, achieving partition incremental refresh without refreshing the entire materialized view.

For Synchronous Materialized Views

- Can be understood as real-time refresh, maintaining consistency with the base table data.

Sync-Materialized View

What is a Synchronous Materialized View

A synchronous materialized view is a special type of table in Doris that stores pre-computed data sets based on defined SELECT statements. Doris automatically maintains the data in synchronous materialized views, ensuring that any new imports or deletions in the base table are reflected in the materialized view in real-time, maintaining data consistency without requiring any additional manual maintenance. When querying, Doris automatically selects the optimal materialized view and retrieves data directly from it.

Applicable Scenarios

- Accelerating time-consuming aggregation operations
- Queries requiring prefix index matching
- Reducing the amount of data scanned by pre-filtering
- Speeding up queries by pre-computing complex expressions

Limitations

- Synchronous materialized views only support SELECT statements for a single table, including WHERE, GROUP BY, and ORDER BY clauses, but not JOIN, HAVING, LIMIT clauses, LATERAL VIEW.
- Unlike asynchronous materialized views, synchronous materialized views cannot be queried directly.
- The SELECT list cannot include auto-increment columns, constants, duplicate expressions, or window functions.
- If the SELECT list contains aggregation functions, these must be root expressions (e.g., $\text{sum}(a + 1)$ is supported, but $\text{sum}(a) + 1$ is not), and no non-aggregation function expressions can follow the aggregation function (e.g., `SELECT x, sum(a)` is allowed, but `SELECT sum(a), x` is not).
- If the condition column for a DELETE statement exists in the materialized view, the DELETE operation cannot proceed. If data deletion is necessary, the materialized view must be dropped first.
- Excessive materialized views on a single table can impact import efficiency. When importing data, both the materialized views and the base table are updated synchronously. Excessive materialized views on a table can slow down imports, similar to importing data into multiple tables simultaneously.
- Materialized views on Unique Key data models can only reorder columns and do not support aggregation. Therefore, coarse-grained aggregation operations cannot be performed through materialized views on Unique Key models.

Using Materialized Views

Doris provides a comprehensive set of DDL syntax for materialized views, including creation, viewing, and deletion. Below is an example demonstrating how to use materialized views to accelerate aggregation calculations. Suppose a user has a sales record detail table that stores transaction IDs, salespersons, stores, sale dates, and amounts. The table creation and data insertion statements are as follows:

```
-- Create a test_db
create database test_db;
use test_db;

-- Create table
create table sales_records
(
    record_id int,
    seller_id int,
    store_id int,
    sale_date date,
    sale_amt bigint
)
distributed by hash(record_id)
properties("replication_num" = "1");

-- Insert data
insert into sales_records values(1,1,1,"2020-02-02",1), (1,1,1,"2020-02-02",2);
```

Creating a Materialized View

If users frequently need to analyze sales volumes by different stores, they can create a materialized view for the sales_records table, grouped by store ID and summing sales amounts for each store. The creation statement is as follows:

```
create materialized view store_amt as
select store_id, sum(sale_amt) from sales_records group by store_id;
```

Checking if the Materialized View is Created

Since creating a materialized view is an asynchronous operation, users need to check the status of the materialized view creation task asynchronously after submitting it. The command is as follows:

```
show alter table materialized view from test_db;
```

The output will show all materialized view creation tasks for that database. A sample output is:

| JobId | TableName | CreateTime | FinishTime | BaseIndexName | RollupIndexName |
|----------|---------------|---------------------|---------------------|---------------|-----------------|
| RollupId | TransactionId | State | Msg | Progress | Timeout |
| 494349 | sales_records | 2020-07-30 20:04:56 | 2020-07-30 20:04:57 | sales_records | store_amt |
| 494350 | 133107 | FINISHED | NULL | 2592000 | |

```

| OUTPUT EXPRS:

| MaterializedView
| MaterializedViewRewriteSuccessAndChose:
|   internal.test_db.sales_records.store_amt chose,
|
| MaterializedViewRewriteSuccessButNotChose:
|   not chose: none,
|
| MaterializedViewRewriteFail:
|
| ===== STATISTICS =====
| planned with unknown column statistics
+-----+

```

MaterializedViewRewriteSuccessAndChose displays the materialized view that was successfully matched, as shown in the following example:

```
+-----+
| MaterializedViewRewriteSuccessAndChose: |
|   internal.test_db.sales_records.store_amt chose, |
+-----+
```

The above content indicates that the query successfully matched the materialized view named store_amt. It's worth noting that if there is no data in the target table, the materialized view may not be hit.

Detailed explanations on MATERIALIZATIONS:

- **MaterializedViewRewriteSuccessAndChose:** Displays the materialized view that was successfully selected and used for query optimization.
- **MaterializedViewRewriteSuccessButNotChose:** Displays materialized views that matched the query but were not selected (the optimizer chooses the optimal materialized view based on its cost, and these matched but unselected views indicate they were not the optimal choice).
- **MaterializedViewRewriteFail:** Displays materialized views that failed to match the query, meaning the original SQL query could not match any existing materialized views and therefore could not be optimized using them.

Dropping a Materialized View

```
drop materialized view store_amt on sales_records;
```

Usage Examples

Below are additional examples demonstrating the use of materialized views.

Example 1: Accelerating Aggregation Queries

Business Scenario: Calculating ad UV (Unique Visitors) and PV (Page Views).

1. Assuming the raw ad click data is stored in Doris, creating a materialized view with bitmap_union can speed up queries for ad PV and UV. First, create a table to store ad click details:

```
create table advertiser_view_record
(
    click_time datetime,
    advertiser varchar(10),
    channel varchar(10),
    user_id int
) distributed by hash(user_id) properties("replication_num" = "1");
insert into advertiser_view_record values("2020-02-02 02:02:02", 'a', 'a', 1), ("2020-02-02
02:02:02", 'a', 'a', 2);
```

2. Since users want to query the UV value of advertisements, which requires an exact deduplication of users for the same advertisement, the typical query would be:

```

select
    advertiser,
    channel,
    count(distinct user_id)
from
    advertiser_view_record
group by
    advertiser, channel;

```

- For this UV calculation scenario, we can create a materialized view with `bitmap_union` to achieve pre-exact deduplication. In Doris, the result of the `count(distinct)` aggregation is identical to the result of the `bitmap_union_count` aggregation. And `bitmap_union_count` is equivalent to counting the results of `bitmap_union`. Therefore, if the query involves `count(distinct)`, creating a materialized view with `bitmap_union` aggregation can speed up the query. Based on current usage scenarios, a materialized view can be created to group by advertisement and channel, with exact deduplication for `user_id`.

```

create materialized view advertiser_uv as
select
    advertiser,
    channel,
    bitmap_union(to_bitmap(user_id))
from
    advertiser_view_record
group by
    advertiser, channel;

```

- Once the materialized view table is created, when querying the UV for advertisements, Doris will automatically retrieve data from the newly created materialized view `advertiser_uv`. If the previous SQL is executed:

```

select
    advertiser,
    channel,
    count(distinct user_id)
from
    advertiser_view_record
group by
    advertiser, channel;

```

- After selecting the materialized view, the actual query will be transformed into:

```

select
    advertiser,
    channel,
    bitmap_union_count(to_bitmap(user_id))
from
    advertiser_uv
group by
    advertiser, channel;

```

- Use the `explain` command to check if the query matches the materialized view:

```

explain select
    advertiser,
    channel,

```

```

count(distinct user_id)
from
  advertiser_view_record
group by
  advertiser, channel;

```

7. The output will be:

```

|
| ===== MATERIALIZATIONS =====
|
|
| MaterializedView
|
| MaterializedViewRewriteSuccessAndChose:
|
| internal.test_db.advertiser_view_record.advertiser_uv chose,
|
|

```

```

|
| MaterializedViewRewriteSuccessButNotChose:
|
|   not chose: none,
|
|
|
|
| MaterializedViewRewriteFail:
|
|
|
|
|
|
| ===== STATISTICS =====
|
| planed with unknown column statistics
|
+-----+
-----+

```

8. In the result of the explain command, you can see that `internal.test_db.advertiser_view_record.advertiser_uv` was chosen. This indicates that the query will directly scan the data from the materialized view. This confirms that the match was successful. Secondly, the `count(distinct)` operation on the `user_id` field is rewritten as `bitmap_union_count(to_bitmap)`. This means that the exact deduplication effect is achieved through the use of Bitmap.

Example 2: Matching Different Prefix Indexes

Business Scenario: Matching prefix indexes.

1. If a table has prefix indexes on `k1` and `k2`, but queries sometimes involve `k3`, a materialized view can be created with `k3` as the first column to leverage indexing:

```

create table test_table
(
    k1 int,
    k2 int,
    k3 int,
    kx date
)
distributed by hash(k1)
properties("replication_num" = "1");

insert into test_table values(1,1,1,1),(3,3,3,3);

```

2. Create a materialized view with `k3` as the prefix index:

```

create materialized view mv_1 as SELECT k3, k2, k1 FROM test_table;

```

3. Queries with `WHERE k3 = 3` will match the materialized view, as verified by explain.

```

explain select k1, k2, k3 from test_table where k3=3;

```

4. The output will be:

```

+-----+
| Explain String(Nereids Planner) |

+-----+

```

5. In the result of the explain command, you can see that `internal.test_db.test_table.mv_1` was chosen, indicating that the query hit the materialized view.

Example 3: Pre-filtering and Expression Computation to Accelerate Queries

Business Scenario: Pre-filtering data or accelerating expression computation.

1. Create a table and materialized views for pre-filtering and expression computation:

```

create table d_table (
  k1 int null,
  k2 int not null,
  k3 bigint null,
  k4 date null
)
duplicate key (k1,k2,k3)
distributed BY hash(k1) buckets 3
properties("replication_num" = "1");

```

```

insert into d_table select 1,1,1,'2020-02-20';
insert into d_table select 2,2,2,'2021-02-20';
insert into d_table select 3,-3,null,'2022-02-20';

```

2. Creating Some Materialized Views:

```

-- mv1 Perform expression calculations ahead of time
create materialized view mv1 as
select
    abs(k1)+k2+1,
    sum(abs(k2+2)+k3+3)
from
    d_table
group by
    abs(k1)+k2+1;

-- mv2 Use where expressions to filter in advance to reduce the amount of data in materialized views
create materialized view mv2 as
select
    year(k4),
    month(k4)
from
    d_table
where
    year(k4) = 2020;

```

3. Testing Whether the Materialized Views Are Successfully Hit with Some Queries:

```

-- Hit mv1
select
    abs(k1)+k2+1,
    sum(abs(k2+2)+k3+3)
from
    d_table
group by
    abs(k1)+k2+1;

-- Hit mv1
select
    bin(abs(k1)+k2+1),
    sum(abs(k2+2)+k3+3)
from
    d_table
group by
    bin(abs(k1)+k2+1);

-- Hit mv2
select
    year(k4) + month(k4)
from
    d_table
where
    year(k4) = 2020;

-- Hit table d_table but not hit mv2, because where condition does not match
select
    year(k4),
    month(k4)
from
    d_table;

```

FAQ

1. Why isn't the rewrite successful after creating a materialized view?

If no matching data is found, it might be because the materialized view is still in the building process. In this case, you can use the following command to check the build status of the materialized view:

```
show alter table materialized view from test_db;
```

If the query result shows that the `status` field is not `FINISHED`, you need to wait until the status becomes `FINISHED` before the materialized view becomes available.

2. When upgrading from 2.x to 3.0.0, why aren't the previous synchronous materialized views being hit?

Starting from version 3.0.0, transparent rewriting of synchronous materialized views uses plan structure information by default. If you find that materialized views that previously worked in 2.x are not being hit in 3.0.0, you can disable the following switch (which is enabled by default):

```
``sqlSET enable_sync_mv_cost_based_rewrite = true;`
```

Overview of Asynchronous Materialized Views

Materialized views, as an efficient solution, combine the flexibility of views with the high performance advantages of physical tables. They can pre-compute and store the result sets of queries, allowing for quick retrieval of results directly from the stored materialized view when query requests arrive, thus avoiding the overhead of re-executing complex query statements.

Use Cases

- **Query Acceleration and Concurrency Improvement:** Materialized views can significantly enhance query speed while boosting the system's concurrent processing capabilities, effectively reducing resource consumption.
- **Simplifying ETL Processes:** During the Extract, Transform, Load (ETL) process, materialized views can streamline workflows, improve development efficiency, and make data processing smoother.
- **Accelerating External Table Queries in Lakehouse Architecture:** In a lakehouse architecture, materialized views can significantly enhance the query speed for external data sources, improving data access efficiency.
- **Improving Write Efficiency:** By reducing resource contention, materialized views can optimize the data writing process, enhance write efficiency, and ensure data consistency and integrity.

Limitations

- **Consistency of Asynchronous Materialized Views with Base Table Data:** Asynchronous materialized views will eventually be consistent with the base table data, but they cannot be synchronized in real-time, meaning real-time consistency cannot be maintained.
- **Support for Window Function Queries:** Currently, if a query contains window functions, it is not supported to transparently rewrite that query to utilize materialized views.
- **Materialized Views Joining More Tables than Query Tables:** If the number of tables joined in the materialized view exceeds the number of tables involved in the query (for example, if the query only involves t1 and t2, while the materialized view includes t1, t2, and an additional t3), the system currently does not support transparently rewriting that query to utilize the materialized view.
- If the materialized view contains set operations such as UNION ALL, LIMIT, ORDER BY, or CROSS JOIN, the materialized view can be built normally, but it cannot be used for transparent rewriting.

Principle Introduction

Materialized views, as an advanced feature in databases, essentially function as MTMV-type internal tables. When creating a materialized view, the system simultaneously registers a refresh task. This task will run when needed, executing an INSERT OVERWRITE statement to write the latest data into the materialized view.

Refresh Mechanism

Unlike the real-time incremental refresh used by synchronous materialized views, asynchronous materialized views offer more flexible refresh options.

- **Full Refresh:**

In this mode, the system recalculates all data involved in the SQL definition of the materialized view and writes the complete results into the materialized view. This process ensures that the data in the materialized view remains consistent with the base table data, but it may consume more computational resources and time.

- **Partition Incremental Refresh:**

When the partition data of the base table for the materialized view changes, the system can intelligently identify these changes and refresh only the affected partitions. This mechanism significantly reduces the computational resources and time required to refresh the materialized view while ensuring eventual data consistency.

Transparent Rewriting:

Transparent rewriting is an important means for databases to optimize query performance. When processing user queries, the system can automatically optimize and rewrite the SQL to improve execution efficiency and reduce computational costs. This rewriting process is transparent to the user, requiring no intervention.

Doris asynchronous materialized views utilize a transparent rewriting algorithm based on the SPJG (SELECT-PROJECT-JOIN-GROUP-BY) model. This algorithm can deeply analyze the structural information of SQL, automatically searching for and selecting suitable materialized views for transparent rewriting. When multiple materialized views are available, the algorithm will also choose the optimal materialized view to respond to the query SQL based on certain strategies (such as cost models), further enhancing query performance.

Support for Materialized Refresh Data Lake

The support for materialized refresh data lakes varies by table type and catalog.

| Table Type | Catalog Type | Refresh Method | | Triggered Refresh |
|----------------|--------------|------------------|-------------------|--------------------|
| | | Full Refresh | Partition Refresh | Auto Trigger |
| Internal Table | Internal | Supported in 2.1 | Supported in 2.1 | Supported in 2.1.4 |
| Hive | Hive | Supported in 2.1 | Supported in 2.1 | Not supported |
| Iceberg | Iceberg | Supported in 2.1 | Not supported | Not supported |
| Paimon | Paimon | Supported in 2.1 | Not supported | Not supported |
| Hudi | Hudi | Supported in 2.1 | Not supported | Not supported |
| JDBC | JDBC | Supported in 2.1 | Not supported | Not supported |
| ES | ES | Supported in 2.1 | Not supported | Not supported |

Transparent Rewriting Support for Data Lake

Currently, the transparent rewriting feature of asynchronous materialized views supports the following types of tables and catalogs.

Real-time Base Table Data Awareness: Refers to the materialized view's ability to detect changes in the underlying table data it uses and utilize the latest data during queries.

| Table Type | Catalog Type | Transparent Rewriting Support | Real-time Base Table Data Awareness |
|----------------|--------------|-------------------------------|-------------------------------------|
| Internal Table | Internal | Supported | Supported |
| Hive | Hive | Supported | 3.1 Supported |
| Iceberg | Iceberg | Supported | 3.1 Supported |
| Paimon | Paimon | Supported | 3.1 Supported |
| Hudi | Hudi | Supported | 3.1 Supported |
| JDBC | JDBC | Supported | Not Supported |
| ES | ES | Supported | Not Supported |

Materialized views using external tables do not participate in transparent rewriting by default, because they cannot detect changes in external table data and cannot guarantee the data in the materialized view is up-to-date. If you want to enable transparent rewriting for materialized views containing external tables, you can set `SET materialized_view_rewrite_enable_contain_external_table = true`.

Since version 2.1.11, Doris has optimized the transparent rewriting performance for external tables, mainly improving the performance of obtaining available materialized views containing external tables.

For partitioned materialized views containing external tables, if transparent rewriting is slow, you need to configure in `fe.conf`: `max_hive_partition_cache_num = 20000`, the maximum number of Hive Metastore table-level partition caches, with a default value of 10000. If the external Hive table has many partitions, you can set this value higher.

`external_cache_expire_time_minutes_after_access`, the duration after last access when cache expires. Default is 10 minutes, can be appropriately increased. (Applies to external table schema cache and Hive metadata cache)

`external_cache_refresh_time_minutes = 60`, the automatic refresh interval for external table metadata cache. Default is 10 minutes, can be appropriately increased. This configuration is supported starting from version 3.1. For details about external table metadata cache configuration, see [Metadata Cache](#)

Relationship Between Materialized Views and OLAP Internal Tables

Asynchronous materialized views define SQL using the base table's table model without restrictions, which can be detail models, primary key models (merge-on-write and merge-on-read), aggregate models, etc.

The underlying implementation of materialized views relies on OLAP tables of the Duplicate model, which theoretically allows them to support all core functionalities of the Duplicate model. However, to ensure that materialized views can execute data refresh tasks stably and efficiently, we have imposed a series of necessary restrictions on their functionality. The specific restrictions are as follows:

- The partitions of materialized views are automatically created and maintained based on their base tables, so users cannot perform partition operations on materialized views.
- Since there are related jobs (JOB) that need to be processed behind materialized views, commands like `DELETE TABLE` or `RENAME TABLE` cannot be used to operate on materialized views. Instead, the commands specific to the materialized view must be used for these operations.

- The column data types of materialized views are automatically inferred based on the query statement specified at creation, so these data types cannot be modified. Otherwise, it may lead to failures in the refresh tasks of the materialized view.
- Materialized views have some properties that Duplicate tables do not possess, and these properties need to be modified through the commands of the materialized view. Other common properties should be modified using the ALTER TABLE command.

Creating, Querying, and Maintaining Asynchronous Materialized Views

This document provides detailed information about materialized view creation, direct querying of materialized views, query rewriting, and common maintenance operations.

Creating Materialized Views

Permission Requirements

- **Creating Materialized Views:** Requires both materialized view creation permission (same as table creation permission) and query permission for the materialized view creation statement (same as SELECT permission).

Creation Syntax

```
CREATE MATERIALIZED VIEW
[ IF NOT EXISTS ] <materialized_view_name>
[ (<columns_definition>) ]
[ BUILD <build_mode> ]
[ REFRESH <refresh_method> [refresh_trigger]]
[ [DUPLICATE] KEY (<key_cols>) ]
[ COMMENT '<table_comment>' ]
[ PARTITION BY (
{ <partition_col>
| DATE_TRUNC(<partition_col>, <partition_unit>) }
)]
[ DISTRIBUTED BY { HASH (<distribute_cols>) | RANDOM }
[ BUCKETS { <bucket_count> | AUTO } ]
]
[ PROPERTIES (
-- Table property
<table_property>
-- Additional table properties
[ , ... ])
]
AS <query>
```

Refresh Configuration

build_mode Refresh Timing

Determines whether to refresh immediately after materialized view creation. - IMMEDIATE: Refresh immediately (default mode) - DEFERRED: Delayed refresh

refresh_method Refresh Method

- COMPLETE: Refresh all partitions

- **AUTO:** Attempt incremental refresh, only refreshing partitions with data changes since the last materialization. Falls back to full refresh of all partitions if data changes cannot be detected.

refresh_trigger Trigger Methods

- **ON MANUAL Manual Trigger**

Users can trigger materialized view refreshes using SQL statements with the following strategies:

Check for base table partition data changes since last refresh and refresh only changed partitions:

```
REFRESH MATERIALIZED VIEW mvName AUTO;
```

If the base table used in the SQL definition of the materialized view is a JDBC table, Doris cannot perceive changes in the table data. When refreshing the materialized view, it is necessary to specify **COMPLETE**. If **AUTO** is specified, it may result in the base table having data, but the materialized view being empty after the refresh. Currently, when refreshing the materialized view, Doris can only perceive data changes in internal tables and Hive data source tables; support for other data sources is being gradually implemented.

Refresh all materialized view partitions without checking for base table changes:

```
REFRESH MATERIALIZED VIEW mvName COMPLETE;
```

Refresh only specified partitions:

```
REFRESH MATERIALIZED VIEW mvName partitions(partitionName1,partitionName2);
```

tip partitionName can be obtained using `SHOW PARTITIONS FROM mvName`. Starting from version 2.1.3, Hive supports detecting base table partition changes since last refresh. Other external tables don't support this yet. Internal tables have always supported this feature.

- **ON SCHEDULE Scheduled Trigger**

Specify refresh intervals in the materialized view creation statement. You can specify the data refresh interval in the materialized view creation statement using `refreshUnit`, where the refresh time interval unit can be minute, hour, day, week, etc.

Example of full refresh (**REFRESH COMPLETE**) every 10 hours, refreshing all partitions:

```
CREATE MATERIALIZED VIEW mv_6
REFRESH COMPLETE ON SCHEDULE EVERY 10 hour
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT FROM lineitem;
```

Example of incremental refresh (**REFRESH AUTO**) every 10 hours, only refreshing changed partitions or falling back to full refresh if needed (automatic Hive partition calculation supported from version 2.1.3):

```
CREATE MATERIALIZED VIEW mv_7
REFRESH AUTO ON SCHEDULE EVERY 10 hour
PARTITION by(l_shipdate)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT FROM lineitem;
```

- **ON COMMIT Automatic Trigger**

:::tip This feature is available from Apache Doris version 2.1.4 onwards. :::

Automatically triggers materialized view refresh when base table data changes, with refresh partition scope matching “scheduled trigger”.

Example: When partition t1 data changes in base table lineitem, it automatically triggers corresponding materialized view partition refresh:

```
CREATE MATERIALIZED VIEW mv_8
REFRESH AUTO ON COMMIT
PARTITION by(l_shipdate)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT FROM lineitem;
```

Not recommended for frequently changing base tables as it creates frequent materialized refresh tasks, consuming excessive resources.

For more details, see [REFRESH MATERIALIZED VIEW](../../sql-manual/sql-statements/table-and-view/async-materialized-view/REFRESH-MATERIALIZED-VIEW)

Examples

Table Creation Statements

```
CREATE TABLE IF NOT EXISTS lineitem (
  l_orderkey    integer not null,
  l_partkey     integer not null,
  l_suppkey     integer not null,
  l_linenumber  integer not null,
  l_quantity    decimalv3(15,2) not null,
  l_extendedprice decimalv3(15,2) not null,
  l_discount    decimalv3(15,2) not null,
  l_tax         decimalv3(15,2) not null,
  l_returnflag  char(1) not null,
  l_linestatus  char(1) not null,
  l_shipdate    date not null,
  l_commitdate  date not null,
  l_receiptdate date not null,
  l_shipinstruct char(25) not null,
  l_shipmode    char(10) not null,
  l_comment     varchar(44) not null
)
DUPLICATE KEY(l_orderkey, l_partkey, l_suppkey, l_linenumber)
```

```

PARTITION BY RANGE(l_shipdate)
(FROM ('2023-10-17') TO ('2023-11-01') INTERVAL 1 DAY)
DISTRIBUTED BY HASH(l_orderkey) BUCKETS 3;

INSERT INTO lineitem VALUES
(1, 2, 3, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-17', '2023-10-17', '2023-10-17', 'a', 'b', 'yyyyyyyyy'),
(2, 4, 3, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-18', '2023-10-18', '2023-10-18', 'a', 'b', 'yyyyyyyyy'),
(3, 2, 4, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-19', '2023-10-19', '2023-10-19', 'a', 'b', 'yyyyyyyyy');

CREATE TABLE IF NOT EXISTS orders (
  o_orderkey      integer not null,
  o_custkey       integer not null,
  o_orderstatus   char(1) not null,
  o_totalprice    decimalv3(15,2) not null,
  o_orderdate     date not null,
  o_orderpriority char(15) not null,
  o_clerk         char(15) not null,
  o_shippriority  integer not null,
  o_comment       varchar(79) not null
)
DUPLICATE KEY(o_orderkey, o_custkey)
PARTITION BY RANGE(o_orderdate)(
FROM ('2023-10-17') TO ('2023-11-01') INTERVAL 1 DAY)
DISTRIBUTED BY HASH(o_orderkey) BUCKETS 3;

INSERT INTO orders VALUES
(1, 1, 'o', 9.5, '2023-10-17', 'a', 'b', 1, 'yy'),
(1, 1, 'o', 10.5, '2023-10-18', 'a', 'b', 1, 'yy'),
(2, 1, 'o', 11.5, '2023-10-19', 'a', 'b', 1, 'yy'),
(3, 1, 'o', 12.5, '2023-10-19', 'a', 'b', 1, 'yy');

CREATE TABLE IF NOT EXISTS partsupp (
  ps_partkey      INTEGER NOT NULL,
  ps_suppkey      INTEGER NOT NULL,
  ps_availqty     INTEGER NOT NULL,
  ps_supplycost   DECIMALV3(15,2) NOT NULL,
  ps_comment      VARCHAR(199) NOT NULL
)
DUPLICATE KEY(ps_partkey, ps_suppkey)
DISTRIBUTED BY HASH(ps_partkey) BUCKETS 3;

INSERT INTO partsupp VALUES
(2, 3, 9, 10.01, 'supply1'),
(4, 3, 10, 11.01, 'supply2'),
(2, 3, 10, 11.01, 'supply3');

```

Refresh mechanism example 1

In the following example, the refresh timing is set to `BUILD IMMEDIATE` (refresh immediately after creation), the refresh method is set to `REFRESH AUTO` (attempt incremental refresh), which only refreshes partitions that have changed since the last materialization. If incremental refresh is not possible, it will perform a full refresh of all partitions. The trigger method is set to `ON MANUAL`. For non-partitioned full materialized views that have only one partition, if the base table data changes, a full refresh will be required.

```

CREATE MATERIALIZED VIEW mv_1_0
BUILD IMMEDIATE
REFRESH AUTO
ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS

```

```

SELECT
    l_linestatus,
    to_date(o_orderdate) as date_alias,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;

```

Refresh mechanism example 2

In the following example, the refresh timing is set to delayed refresh (`BUILD DEFERRED`), the refresh method is set to full refresh (`REFRESH COMPLETE`), and the trigger timing is set to scheduled refresh (`ON SCHEDULE`). The first refresh time is `2024-12-01 20:30:00`, and it will refresh every day thereafter. If `BUILD DEFERRED` is specified as `BUILD IMMEDIATE`, the materialized view will refresh immediately upon creation. After that, it will refresh every day starting from `2024-12-01 20:30:00`.

The time specified in `STARTS` must be later than the current time.

```

CREATE MATERIALIZED VIEW mv_1_1
BUILD DEFERRED
REFRESH COMPLETE
ON SCHEDULE EVERY 1 DAY STARTS '2024-12-01 20:30:00'
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    to_date(o_orderdate) as date_alias,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;

```

Refresh mechanism example 3

In this example, the refresh timing is set to immediate refresh upon creation (`BUILD IMMEDIATE`), the refresh method is set to full refresh (`REFRESH COMPLETE`), and the trigger method is set to trigger refresh (`ON COMMIT`). When data in the `orders` or `lineitem` tables changes, it will automatically trigger the refresh of the materialized view.

```

CREATE MATERIALIZED VIEW mv_1_1
BUILD IMMEDIATE
REFRESH COMPLETE
ON COMMIT
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    to_date(o_orderdate) as date_alias,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;

```

Partition Configuration

In the following example, when creating a partitioned materialized view, it is necessary to specify `PARTITION BY`. For expressions referencing partition fields, only the `date_trunc` function and identifiers are allowed. The following statement meets the requirements: the partition field references only the `date_trunc` function. The refresh method for partitioned materialized views is generally set to `AUTO`, which attempts incremental refresh, refreshing only the partitions that have changed since the last materialized refresh. If incremental refresh is not possible, it will refresh all partitions.

```
CREATE MATERIALIZED VIEW mv_2_0
BUILD IMMEDIATE
REFRESH AUTO
ON MANUAL
PARTITION BY (order_date_month)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    date_trunc(o_orderdate, 'month') as order_date_month,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;
```

The following statement will fail to create a partitioned materialized view because the partition field `order_date_month` uses the `date_add()` function, resulting in the error because column to check use invalid implicit expression, invalid expression is `date_add(o_orderdate#4, 2)`.

```
CREATE MATERIALIZED VIEW mv_2_1 BUILD IMMEDIATE REFRESH AUTO ON MANUAL
PARTITION BY (order_date_month)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    date_trunc(date_add(o_orderdate, INTERVAL 2 DAY), 'month') as order_date_month,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;
```

Base Table with Multiple Partition Columns

Currently, only Hive external tables support multiple partition columns. Hive external tables often have many multi-level partitions, such as a first-level partition by date and a second-level partition by region. Materialized views can choose one of Hive's partition columns as the partition column for the materialized view.

For example, the Hive table creation statement is as follows:

```
CREATE TABLE hive1 (
`k1` int)
PARTITIONED BY (
`year` int,
`region` string)
STORED AS ORC;
```

```
alter table hive1 add if not exists
partition(year=2020,region="bj")
partition(year=2020,region="sh")
partition(year=2021,region="bj")
partition(year=2021,region="sh")
partition(year=2022,region="bj")
partition(year=2022,region="sh")
```

When the materialized view creation statement is as follows, the materialized view mv_hive will have three partitions: ('2020'), ('2021'), and ('2022').

```
CREATE MATERIALIZED VIEW mv_hive
BUILD DEFERRED
REFRESH AUTO
ON MANUAL
PARTITION BY (year)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT k1, year, region FROM hive1;
```

When the materialized view creation statement is as follows, the materialized view mv_hive2 will have the following two partitions: ('bj ') and ('sh '):

```
CREATE MATERIALIZED VIEW mv_hive2
BUILD DEFERRED
REFRESH AUTO
ON MANUAL
PARTITION BY (region)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT k1, year, region FROM hive1;
```

Using Partial Partitions from the Base Table

Some base tables have many partitions, but the materialized view only focuses on the “hot” data from a recent period. This feature allows for that.

The base table creation statement is as follows:

```
CREATE TABLE t1 (
k1 INT,
k2 DATE NOT NULL
) ENGINE=OLAP
DUPLICATE KEY(k1)
COMMENT 'OLAP'
PARTITION BY range(k2)
(
PARTITION p26 VALUES [("2024-03-26"),("2024-03-27")),
PARTITION p27 VALUES [("2024-03-27"),("2024-03-28")),
PARTITION p28 VALUES [("2024-03-28"),("2024-03-29"))
)
DISTRIBUTED BY HASH(k1) BUCKETS 2;
```

The materialized view creation statement is as follows, indicating that the materialized view only focuses on the data from the most recent day. If the current time is 2024-03-28 xx:xx:xx, the materialized view will only have

one partition [("2024-03-28"), ("2024-03-29")]:

```
CREATE MATERIALIZED VIEW mv1
BUILD DEFERRED
REFRESH AUTO
ON MANUAL
PARTITION BY (k2)
DISTRIBUTED BY RANDOM BUCKETS 2
PROPERTIES (
'partition_sync_limit'='1',
'partition_sync_time_unit'='DAY'
)
AS
SELECT FROM t1;
```

If the time passes another day, and the current time is 2024-03-29 xx:xx:xx, t1 will add a new partition [("2024-03-29"), ("2024-03-30")]. If the materialized view is refreshed at this time, after the refresh is complete, the materialized view will only have one partition [("2024-03-29"), ("2024-03-30")].

Additionally, when the partition field is of string type, the materialized view property `partition_date_format` can be set, for example, `%Y-%m-%d`.

Partition Aggregation

Range partitioning is supported since Doris 2.1.5

When the data in the base table is aggregated, the amount of data in each partition may significantly decrease. In this case, a partition aggregation strategy can be adopted to reduce the number of partitions in the materialized view.

Assuming the base table creation statement is as follows:

```
CREATE TABLE t1 (
k1 LARGEINT NOT NULL,
k2 DATE NOT NULL
) ENGINE=OLAP
DUPLICATE KEY(k1)
COMMENT 'OLAP'
PARTITION BY range(k2)
(
PARTITION p_20200101 VALUES [ ("2020-01-01"), ("2020-01-02") ),
PARTITION p_20200102 VALUES [ ("2020-01-02"), ("2020-01-03") ),
PARTITION p_20200201 VALUES [ ("2020-02-01"), ("2020-02-02") )
)
DISTRIBUTED BY HASH(k1) BUCKETS 2;
```

If the materialized view creation statement is as follows, the materialized view will contain two partitions: [("2020-01-01", "2020-02-01")] and [("2020-02-01", "2020-03-01")].

```
CREATE MATERIALIZED VIEW mv_3
BUILD DEFERRED
REFRESH AUTO
ON MANUAL
```

```
PARTITION BY (date_trunc(k2,'month'))
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT FROM t1;
```

If the materialized view creation statement is as follows, the materialized view will only contain one partition: `[("2020-01-01","2021-01-01")]`.

```
CREATE MATERIALIZED VIEW mv_4
BUILD DEFERRED
REFRESH AUTO
ON MANUAL
PARTITION BY (date_trunc(k2,'year'))
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT FROM t1;
```

Additionally, if the partition field is of string type, the date format can be specified by setting the materialized view's `partition_date_format` property, for example, `'%Y-%m-%d'`.

For more details, refer to [CREATE ASYNC MATERIALIZED VIEW](#).

SQL Definition

Asynchronous materialized views do not support creation using View.

Direct Querying of Materialized Views

Materialized views can be treated like tables, allowing for the addition of filtering conditions and aggregations for direct querying.

Definition of Materialized View:

```
CREATE MATERIALIZED VIEW mv_5
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
SELECT t1.l_linenumber,
o_custkey,
o_orderdate
FROM (SELECT FROM lineitem WHERE l_linenumber > 1) t1
LEFT OUTER JOIN orders
ON l_orderkey = o_orderkey;
```

Original Query:

```
SELECT t1.l_linenumber,
o_custkey,
o_orderdate
FROM (SELECT FROM lineitem WHERE l_linenumber > 1) t1
LEFT OUTER JOIN orders
ON l_orderkey = o_orderkey
WHERE o_orderdate = '2023-10-18';
```

Equivalent Direct Query on Materialized View: Users need to manually modify the query.

```
SELECT l_linenumber,  
o_custkey,  
o_orderdate  
FROM mv_5  
WHERE o_orderdate = '2023-10-18';
```

Transparent Query Rewriting

Transparent rewriting means that when processing queries, users do not need to manually modify queries, as the system will automatically optimize and rewrite them. Doris asynchronous materialized views use a transparent rewriting algorithm based on the SPJG (SELECT-PROJECT-JOIN-GROUP-BY) pattern. This algorithm can analyze SQL structure information, automatically find suitable materialized views for transparent rewriting, and select the optimal materialized view to respond to query SQL. Doris provides rich and comprehensive transparent rewriting capabilities. For example, the following capabilities:

Condition Compensation

Query and materialized view conditions do not need to be exactly the same. By compensating conditions on materialized views to express queries, materialized views can be reused to the maximum extent, avoiding the need to repeatedly build materialized views.

When the where conditions in the materialized view and query are expressions connected by and:

1. When the query's expressions contain the materialized view's expressions:

Condition compensation can be performed.

For example, if the query condition is $a > 5$ and $b > 10$ and $c = 7$, and the materialized view condition is $a > 5$ and $b > 10$, the materialized view condition is a subset of the query condition, so only the $c = 7$ condition needs to be compensated.

2. When the query's expressions do not completely contain the materialized view's expressions:

When the query conditions can be derived from the materialized view conditions (common for comparison and range expressions like $>$, $<$, $=$, in , etc.), condition compensation can also be performed. The compensation result is the query condition itself.

For example, if the query condition is $a > 5$ and $b = 10$, and the materialized view condition is $a > 1$ and $b > 8$, it can be seen that the materialized view condition contains the query condition, and the query condition can be derived from the materialized view condition, so compensation can be performed, with the compensation result being $a > 5$ and $b = 10$.

Condition compensation usage restrictions:

3. For expressions connected by `or`, condition compensation cannot be performed; they must be exactly the same for successful rewriting.
4. For non-comparison and non-range expressions like `like`, condition compensation cannot be performed; they must be exactly the same for successful rewriting.

For example:

Materialized View Definition:

```
```sql
CREATE MATERIALIZED VIEW mv1
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
SELECT t1.l_linenum,
 o_custkey,
 o_orderdate
FROM (SELECT * FROM lineitem WHERE l_linenum > 1) t1
LEFT OUTER JOIN orders
ON l_orderkey = o_orderkey;
```
```

The following queries can all hit the materialized view. Multiple queries can reuse one materialized view through transparent rewriting, reducing query rewriting time and saving materialized view construction costs.

```
```sql
SELECT l_linenum,
 o_custkey,
 o_orderdate
FROM lineitem
LEFT OUTER JOIN orders
ON l_orderkey = o_orderkey
WHERE l_linenum > 2;
```

```sql
SELECT l_linenum,
 o_custkey,
 o_orderdate
FROM lineitem
LEFT OUTER JOIN orders
ON l_orderkey = o_orderkey
WHERE l_linenum > 2 and o_orderdate = '2023-10-19';
```
```

JOIN Rewriting

JOIN rewriting refers to when the query and materialized view use the same tables, and conditions can be written in the materialized view, JOIN inputs, or outside the JOIN. The optimizer will attempt transparent rewriting for queries in this pattern.

Multiple table JOINS are supported, with the following supported JOIN types:

- INNER JOIN
- LEFT OUTER JOIN
- RIGHT OUTER JOIN
- FULL OUTER JOIN
- LEFT SEMI JOIN
- RIGHT SEMI JOIN
- LEFT ANTI JOIN

- RIGHT ANTI JOIN

For example:

Materialized View Definition:

```
CREATE MATERIALIZED VIEW mv2
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
SELECT t1.l_linenum,
       o_custkey,
       o_orderkey,
       o_orderstatus,
       l_partkey,
       l_suppkey,
       l_orderkey
FROM (SELECT * FROM lineitem WHERE l_linenum > 1) t1
INNER JOIN orders ON t1.l_orderkey = orders.o_orderkey;
```

The following query can be transparently rewritten. The condition `l_linenum > 1` can be lifted up, enabling transparent rewriting to use the materialized view's pre-computed results to express the query. After hitting the materialized view, JOIN computation can be saved.

Query Statement:

```
SELECT l_linenum,
       o_custkey
FROM lineitem
INNER JOIN orders ON l_orderkey = o_orderkey
WHERE l_linenum > 1 and o_orderdate = '2023-10-18';
```

JOIN Derivation

When the JOIN types in the query and materialized view are inconsistent, if the materialized view can provide all the data needed by the query, transparent rewriting can still be performed by compensating predicates outside the JOIN.

For example:

Materialized View Definition:

```
CREATE MATERIALIZED VIEW mv3
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
SELECT
  l_shipdate, l_suppkey, o_orderdate,
  sum(o_totalprice) AS sum_total,
  max(o_totalprice) AS max_total,
  min(o_totalprice) AS min_total,
  count(*) AS count_all,
  count(distinct CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null END) AS
  bitmap_union_basic
FROM lineitem
LEFT OUTER JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate
GROUP BY
```

```
l_shipdate,  
l_suppkey,  
o_orderdate;
```

Query Statement:

```
SELECT  
    l_shipdate, l_suppkey, o_orderdate,  
    sum(o_totalprice) AS sum_total,  
    max(o_totalprice) AS max_total,  
    min(o_totalprice) AS min_total,  
    count(*) AS count_all,  
    count(distinct CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null END) AS  
bitmap_union_basic  
FROM lineitem  
INNER JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate  
WHERE o_orderdate = '2023-10-18' AND l_suppkey = 3  
GROUP BY  
    l_shipdate,  
    l_suppkey,  
    o_orderdate;
```

Aggregate Rewriting

When the group dimensions in the query and materialized view definition are consistent, if the materialized view uses the same group by dimensions as the query, and the aggregate functions used in the query can be expressed using the materialized view's aggregate functions, transparent rewriting can be performed.

For example:

Materialized View Definition:

```
CREATE MATERIALIZED VIEW mv4  
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour  
DISTRIBUTED BY RANDOM BUCKETS 3  
AS  
SELECT  
    o_shippriority, o_comment,  
    count(distinct CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null END) AS  
cnt_1,  
    count(distinct CASE WHEN O_SHIPPRIORITY > 2 AND o_orderkey IN (2) THEN o_custkey ELSE null END) AS cnt_2,  
    sum(o_totalprice),  
    max(o_totalprice),  
    min(o_totalprice),  
    count(*)  
FROM orders  
GROUP BY  
    o_shippriority,  
    o_comment;
```

The following query can hit the materialized view, as it uses the same aggregation dimensions as the materialized view. The query can filter results using the materialized view's `o_shippriority` field. The query's group by dimensions and aggregate functions can be rewritten using the materialized view's group by dimensions and aggregate functions. After hitting the aggregate materialized view, aggregation computation can be reduced.

Query Statement:

```
SELECT
    o_shippriority, o_comment,
    count(distinct CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null END) AS
cnt_1,
    count(distinct CASE WHEN O_SHIPPRIORITY > 2 AND o_orderkey IN (2) THEN o_custkey ELSE null END) AS cnt_2,
    sum(o_totalprice),
    max(o_totalprice),
    min(o_totalprice),
    count(*)
FROM orders
WHERE o_shippriority in (1, 2)
GROUP BY
    o_shippriority,
    o_comment;
```

Aggregate Rewriting (Roll-up)

Even when the aggregation dimensions in the query and materialized view definition are inconsistent, rewriting can still be performed. The materialized view's group by dimensions need to include the query's group by dimensions, and the query may not have any group by. Additionally, the aggregate functions used in the query must be expressible using the materialized view's aggregate functions.

For example:

Materialized View Definition:

```
CREATE MATERIALIZED VIEW mv5
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
SELECT
    l_shipdate, o_orderdate, l_partkey, l_suppkey,
    sum(o_totalprice) AS sum_total,
    max(o_totalprice) AS max_total,
    min(o_totalprice) AS min_total,
    count(*) AS count_all,
    bitmap_union(to_bitmap(CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null
END)) AS bitmap_union_basic
FROM lineitem
LEFT OUTER JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate
GROUP BY
    l_shipdate,
    o_orderdate,
    l_partkey,
    l_suppkey;
```

The following query can be transparently rewritten. The query and materialized view use different aggregation dimensions, but the materialized view's dimensions include the query's dimensions. The query can use fields from the dimensions to filter results. The query will attempt to roll up using the functions after the materialized view's SELECT, for example, the materialized view's `bitmap_union` will eventually roll up to `bitmap_union_count`, which maintains the same semantics as the query's `count(distinct)`.

Through aggregate roll-up, the same materialized view can be reused by multiple queries, saving materialized view construction costs.

Query Statement:

```
SELECT
    l_shipdate, l_suppkey,
    sum(o_totalprice) AS sum_total,
    max(o_totalprice) AS max_total,
    min(o_totalprice) AS min_total,
    count(*) AS count_all,
    count(distinct CASE WHEN o_shippriority > 1 AND o_orderkey IN (1, 3) THEN o_custkey ELSE null END) AS
    bitmap_union_basic
FROM lineitem
LEFT OUTER JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate
WHERE o_orderdate = '2023-10-18' AND l_partkey = 3
GROUP BY
    l_shipdate,
    l_suppkey;
```

Currently supported aggregate roll-up functions are listed below:

| Query Function | Materialized View Function | Function After Roll-up |
|---|--|------------------------|
| max | max | max |
| min | min | min |
| sum | sum | sum |
| count | count | sum |
| count(distinct) | bitmap_union | bitmap_union_count |
| bitmap_union | bitmap_union | bitmap_union |
| bitmap_union_count | bitmap_union | bitmap_union_count |
| hll_union_agg,
approx_count_distinct,
hll_cardinality | hll_union or hll_raw_agg | hll_union_agg |
| any_value | any_value or column used after any_value in select | any_value |

Multi-dimensional Aggregate Rewriting

Multi-dimensional aggregate transparent rewriting is supported, meaning that if the materialized view does not use `GROUPING SETS`, `CUBE`, or `ROLLUP`, but the query has multi-dimensional aggregation, and the materialized view's group by fields include all fields in the query's multi-dimensional aggregation, transparent rewriting can still be performed.

For example:

Materialized View Definition:

```
CREATE MATERIALIZED VIEW mv5_1
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 hour
DISTRIBUTED BY RANDOM BUCKETS 3
AS
select o_orderstatus, o_orderdate, o_orderpriority,
    sum(o_totalprice) as sum_total,
    max(o_totalprice) as max_total,
```

```

        min(o_totalprice) as min_total,
        count(*) as count_all
    from orders
    group by
    o_orderstatus, o_orderdate, o_orderpriority;

```

The following query can hit the materialized view, reusing the materialized view's aggregate results and saving computation:

Query Statement:

```

select o_orderstatus, o_orderdate, o_orderpriority,
       sum(o_totalprice),
       max(o_totalprice),
       min(o_totalprice),
       count(*)
from orders
group by
GROUPING SETS ((o_orderstatus, o_orderdate), (o_orderpriority), (o_orderstatus), ());

```

Partition Compensation Rewriting

When a partitioned materialized view cannot provide all the data needed by the query, a union all approach can be used, combining data from the original table and the materialized view as the final result.

For example:

Materialized View Definition:

```

CREATE MATERIALIZED VIEW mv7
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
partition by(l_shipdate)
DISTRIBUTED BY RANDOM BUCKETS 2
as
select l_shipdate, o_orderdate, l_partkey,
       l_suppkey, sum(o_totalprice) as sum_total
from lineitem
left join orders on lineitem.l_orderkey = orders.o_orderkey and l_shipdate = o_orderdate
group by
    l_shipdate,
    o_orderdate,
    l_partkey,
    l_suppkey;

```

When the base table adds a partition 2023-10-21 and the materialized view hasn't been refreshed yet, results can be returned by using union all between the materialized view and the original table.

```

insert into lineitem values
(1, 2, 3, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-21', '2023-10-21', '2023-10-21', 'a', 'b', 'yyyyyyyyy');

```

Query Statement:

```

select l_shipdate, o_orderdate, l_partkey, l_suppkey, sum(o_totalprice) as sum_total
from lineitem
left join orders on lineitem.l_orderkey = orders.o_orderkey and l_shipdate = o_orderdate

```

```
group by
    l_shipdate,
    o_orderdate,
    l_partkey,
    l_suppkey;
```

The query can partially use the materialized view's pre-computed results, saving this portion of computation.

Rewrite Result Illustration:

```
SELECT *
FROM mv7
union all
select t1.l_shipdate, o_orderdate, t1.l_partkey, t1.l_suppkey, sum(o_totalprice) as sum_total
from (select * from lineitem where l_shipdate = '2023-10-21') t1
left join orders on t1.l_orderkey = orders.o_orderkey and t1.l_shipdate = o_orderdate
group by
    t1.l_shipdate,
    o_orderdate,
    t1.l_partkey,
    t1.l_suppkey;
```

Nested Materialized View Rewriting

The SQL definition of a materialized view can use another materialized view; this is called a nested materialized view. There is theoretically no limit to the nesting depth, and this materialized view can be both directly queried and transparently rewritten. Nested materialized views can also participate in transparent rewriting.

For example:

Create inner materialized view mv8_0_inner_mv:

```
CREATE MATERIALIZED VIEW mv8_0_inner_mv
BUILD IMMEDIATE REFRESH COMPLETE ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS
select
    l_linenumber,
    o_custkey,
    o_orderkey,
    o_orderstatus,
    l_partkey,
    l_suppkey,
    l_orderkey
from lineitem
inner join orders on lineitem.l_orderkey = orders.o_orderkey;
```

Create outer materialized view mv8_0:

```
CREATE MATERIALIZED VIEW mv8_0
BUILD IMMEDIATE REFRESH COMPLETE ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS
select
    l_linenumber,
    o_custkey,
```

```

o_orderkey,
o_orderstatus,
l_partkey,
l_suppkey,
l_orderkey,
ps_availqty
from mv8_0_inner_mv
inner join partsupp on l_partkey = ps_partkey AND l_suppkey = ps_suppkey;

```

For the following query, both mv8_0_inner_mv and mv8_0 will be successfully rewritten, and the cost model will ultimately choose mv8_0.

Nested materialized views are commonly used in data modeling and particularly complex queries. If a single materialized view cannot be transparently rewritten, you can split the complex query and build nested materialized views. The transparent rewriting process will attempt to use nested materialized views for rewriting. If the rewrite is successful, it will save computation and improve query performance.

```

select lineitem.l_linenum
from lineitem
inner join orders on l_orderkey = o_orderkey
inner join partsupp on l_partkey = ps_partkey AND l_suppkey = ps_suppkey
where o_orderstatus = 'o'

```

Note:

1. The more layers of nested materialized views, the longer transparent rewriting will take. It is recommended that nested materialized views do not exceed 3 layers.
2. Nested materialized view transparent rewriting is disabled by default. See the related settings below for how to enable it.

Aggregate Query Using Non-Aggregate Materialized View Rewrite

If the query is an aggregate query and the materialized view does not contain aggregates, but the materialized view can provide all the columns used in the query, then it can also be rewritten. For example, if the query first performs a join and then a group by aggregation, hitting a materialized view that includes the join will also yield benefits.

```

CREATE MATERIALIZED VIEW mv10_0
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
as
select l_shipdate, o_orderdate, l_partkey,
       l_suppkey, o_totalprice
from lineitem
left join orders on lineitem.l_orderkey = orders.o_orderkey and l_shipdate = o_orderdate;

```

The following query can hit the mv10_0 materialized view, saving the computation of the lineitem join orders join:

```

select l_shipdate, o_orderdate, l_partkey,
       l_suppkey, sum(o_totalprice) as sum_total
from lineitem
left join orders on lineitem.l_orderkey = orders.o_orderkey and l_shipdate = o_orderdate

```

```
group by
  l_shipdate,
  o_orderdate,
  l_partkey,
  l_suppkey;
```

Explain Query Transparent Rewriting Status

To view materialized view transparent rewriting hits, used for viewing and debugging.

1. **To view materialized view transparent rewriting hit status, this statement will show brief process information about query transparent rewriting.**

```
explain <query_sql>
```

The returned information is as follows, with materialized view-related information excerpted here:

```
| MaterializedView
|
| MaterializedViewRewriteSuccessAndChose:
|
|   Names: mv5
|
| MaterializedViewRewriteSuccessButNotChose:
|
|
|
| MaterializedViewRewriteFail:
|
|   Name: mv4
|
|   FailSummary: Match mode is invalid, View struct info is invalid
|
|   Name: mv3
|
|   FailSummary: Match mode is invalid, Rewrite compensate predicate by view fail, View struct info is
invalid
|
|   Name: mv1
|
|   FailSummary: The columns used by query are not in view, View struct info is invalid
|
|   Name: mv2
|
|   FailSummary: The columns used by query are not in view, View struct info is invalid
```

- **MaterializedViewRewriteSuccessAndChose:** Indicates the list of materialized view names that were successfully transparently rewritten and chosen by CBO (Cost-Based Optimizer).
 - **MaterializedViewRewriteSuccessButNotChose:** Indicates the list of materialized view names that were successfully transparently rewritten but ultimately not chosen by CBO.
 - **MaterializedViewRewriteFail:** Lists the failed cases and summary reasons.
2. **To understand the detailed process information about materialized view candidacy, rewriting, and final selection, execute the following statement:**

```
explain memo plan <query_sql>
```

Maintaining Materialized Views

Permission Requirements

- Dropping materialized views: Requires materialized view deletion permission (same as table deletion permission)
- Modifying materialized views: Requires materialized view modification permission (same as table modification permission)
- Pausing/resuming/canceling/refreshing materialized views: Requires materialized view creation permission

Modifying Materialized Views

Modifying Materialized View Properties

```
ALTER MATERIALIZED VIEW mv_1
SET(
  "grace_period" = "10"
);
```

For more details, see [ALTER ASYNC MATERIALIZED VIEW](#)

Materialized View Renaming, i.e., Atomic Replacement of Materialized Views

```
CREATE MATERIALIZED VIEW mv9_0
BUILD IMMEDIATE REFRESH COMPLETE ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
PROPERTIES ('replication_num' = '1')
AS
select
  l_linenumber,
  o_custkey,
  o_orderkey,
  o_orderstatus,
  l_partkey,
  l_suppkey,
  l_orderkey
from lineitem
inner join orders on lineitem.l_orderkey = orders.o_orderkey;
```

Replace the materialized view mv7 with mv9_0 and delete mv7:

```
ALTER MATERIALIZED VIEW mv7
REPLACE WITH MATERIALIZED VIEW mv9_0
PROPERTIES('swap' = 'false');
```

Dropping Materialized Views

```
DROP MATERIALIZED VIEW mv_1;
```

For more details, see [DROP ASYNC MATERIALIZED VIEW](#)

Viewing Materialized View Creation Statement

```
SHOW CREATE MATERIALIZED VIEW mv_1;
```

For more details, see [SHOW CREATE MATERIALIZED VIEW](#)

Pausing Materialized Views

For more details, see [PAUSE MATERIALIZED VIEW](#)

Resuming Materialized Views

For more details, see [RESUME MATERIALIZED VIEW](#)

Canceling Materialized View Refresh Tasks

For more details, see [CANCEL MATERIALIZED VIEW TASK](#)

Querying Materialized View Information

```
SELECT *
FROM mv_infos('database'='db_name')
WHERE Name = 'mv_name' \G
```

Example output:

```
***** 1. row *****
      Id: 139570
      Name: mv11
      JobName: inner_mtmv_139570
      State: NORMAL
SchemaChangeDetail:
  RefreshState: SUCCESS
  RefreshInfo: BUILD IMMEDIATE REFRESH AUTO ON MANUAL
  QuerySql: SELECT l_shipdate, l_orderkey, O_ORDERDATE, count(*)
FROM lineitem
LEFT OUTER JOIN orders on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_orderkey, O_ORDERDATE
      EnvInfo: EnvInfo{ctlId='0', dbId='16813'}
      MvProperties: {}
      MvPartitionInfo: MTMVPPartitionInfo{partitionType=FOLLOW_BASE_TABLE, relatedTable=lineitem,
relatedCol='l_shipdate', partitionCol='l_shipdate'}
      SyncWithBaseTables: 1
```

- **SyncWithBaseTables:** Indicates whether the materialized view is synchronized with base tables.

- For fully built materialized views, a value of 1 indicates the view is available for transparent rewriting.
- For incrementally partitioned materialized views, availability is determined at the partition level. Even if some partitions are unavailable, the view can still be used for transparent rewriting if the queried partitions are valid. The ability to use transparent rewriting depends on the `SyncWithBaseTables` value of the queried partitions - 1 means available, 0 means unavailable.
- **JobName:** Name of the materialized view's build job. Each materialized view has one Job, and each refresh creates a new Task, with a 1:n relationship between Jobs and Tasks.
- **State:** If changed to `SCHEMA_CHANGE`, indicates the base table's schema has changed. The materialized view cannot be used for transparent rewriting (but can still be queried directly). Will return to `NORMAL` after the next successful refresh task.
- **SchemaChangeDetail:** Explains the reason for `SCHEMA_CHANGE`.
- **RefreshState:** Status of the last refresh task. If `FAIL`, indicates execution failed - use the `tasks()` command to identify the cause. See [Viewing Materialized View Task Status](#) section.
- **SyncWithBaseTables:** Whether synchronized with base tables. 1 means synchronized, 0 means not synchronized. If not synchronized, use `show partitions` to check which partitions are out of sync. See the section below on checking `SyncWithBaseTables` status for partitioned materialized views.

For transparent rewriting, materialized views typically have two states:

- **Normal:** The materialized view is available for transparent rewriting.
- **Unavailable/Abnormal:** The materialized view cannot be used for transparent rewriting. However, it can still be queried directly.

For more details, see [MV_INFOS](#)

Querying Refresh Task Information

Each materialized view has one Job, and each refresh creates a new Task, with a 1:n relationship between Jobs and Tasks. To view a materialized view's Task status by name, run the following query to check refresh task status and progress:

```
SELECT *
FROM tasks("type"="mv")
WHERE
  MvDatabaseName = 'mv_db_name' and
  mvName = 'mv_name'
ORDER BY CreateTime DESC \G
```

Example output:

```
***** 1. row *****
TaskId: 167019363907545
JobId: 139872
JobName: inner_mtmv_139570
MvId: 139570
MvName: mv11
MvDatabaseId: 16813
```

```

```

- NeedRefreshPartitions and CompletedPartitions record the partitions refreshed in this Task.
- Status: If FAILED, indicates execution failed. Check ErrorMsg for failure reason or use LastQueryId to search Doris logs for detailed error information. Currently, task failure makes existing materialized views unavailable. This will be changed so existing materialized views remain available for transparent rewriting even if tasks fail.
- ErrorMsg: Failure reason.
- RefreshMode: COMPLETE means all partitions were refreshed, PARTIAL means some partitions were refreshed, NOT_REFRESH means no partitions needed refreshing.

Note

- Currently, the default storage and display count for tasks is 100. This can be modified by configuring max_persistence_task_count in the fe.conf file. When exceeding this limit, older task records will be discarded. If the value is set to < 1, task persistence will be disabled. After modifying the configuration, a restart of the FE service is required for the changes to take effect.
- If the grace_period property was set when creating the materialized view, it may still be available for transparent rewriting in some cases even if SyncWithBaseTables is false or 0.
- grace_period is measured in seconds and specifies the allowed time for data inconsistency between the materialized view and base tables.
- If set to 0, requires exact consistency between materialized view and base table data for transparent rewriting.
- If set to 10, allows up to 10 seconds of delay between materialized view and base table data. The materialized view can be used for transparent rewriting during this 10-second window. :::

Querying Materialized View Jobs

```
SELECT *
FROM jobs("type"="mv")
WHERE Name="inner_mtmv_75043";
```

For more details, see [JOBS](#)

Querying Materialized View Partition Information

Checking SyncWithBaseTables Status for Partitioned Materialized Views

Run `show partitions` from `mv_name` to check if queried partitions are valid. Example output:

```
show partitions from mv11;
```

| PartitionId | PartitionName | VisibleVersion | VisibleVersionTime | State | PartitionKey | DistributionKey |
|-------------|---------------------|----------------|---------------------|--------|--------------|-----------------|
| 140189 | p_20231016_20231017 | 1 | 2024-06-21 10:31:45 | NORMAL | l_shipdate | l_orderkey |
| 139995 | p_20231018_20231019 | 2 | 2024-06-21 10:31:44 | NORMAL | l_shipdate | l_orderkey |
| 139898 | p_20231019_20231020 | 2 | 2024-06-21 10:31:43 | NORMAL | l_shipdate | l_orderkey |

Check the `SyncWithBaseTables` field - false indicates the partition is not available for transparent rewriting.

For more details, see [SHOW PARTITIONS](#)

Related Configuration

Session Variables

| Variable | Description |
|--|---|
| SET enable_nereids_planner = true; | Async materialized views only work with the new optimizer. Enable this if materialized view transparent rewriting isn't working |
| SET enable_materialized_view_rewrite = true; | Enable/disable query transparent rewriting (enabled by default from version 2.1.5) |
| SET materialized_view_rewrite_enable_contain_external_table = true; | Allow materialized views containing external tables to participate in transparent rewriting (disabled by default) |
| SET materialized_view_rewrite_success_candidate_num = 3; | Maximum number of successful rewrite results allowed in CBO candidates (default 3). Reduce if transparent rewriting is slow |
| SET enable_materialized_view_union_rewrite = true; | Allow UNION ALL between base table and materialized view when partitioned view doesn't provide all needed data (enabled by default) |
| SET enable_materialized_view_nest_rewrite = true; | Allow nested rewrites (disabled by default). Enable if complex queries require nested materialized views |
| SET materialized_view_relation_mapping_max_count = 8; | Maximum allowed relation mappings during transparent rewriting (default 8). Reduce if rewriting is slow |
| SET enable_dml_materialized_view_rewrite = true; | Enable structure-based materialized view transparent rewriting during DML (enabled by default) |
| SET enable_dml_materialized_view_rewrite_when_base_table_unawareness = true; | Enable structure-based materialized view transparent rewriting during DML when view contains external tables that can't be tracked in real-time (disabled by default) |

fe.conf Configuration

- **job_mtmv_task_consumer_thread_num:** Controls the number of concurrent materialized view refresh tasks (default 10). Tasks exceeding this limit will be pending. Requires FE restart to take effect.

Best Practices | Async Materialized View

Best Practices

Principles for Using Asynchronous Materialized Views

- **Timeliness Consideration:** Asynchronous materialized views are typically used in scenarios where data timeliness is not critical, usually T+1 data. If high timeliness is required, consider using synchronous materialized views.
- **Acceleration Effect and Consistency Consideration:** In query acceleration scenarios, when creating materialized views, DBAs should group common query SQL patterns, aiming to minimize overlap between groups. The clearer the SQL pattern grouping, the higher the quality of the materialized view construction. A query may use multiple materialized views, and a materialized view may be used by multiple queries. Constructing materialized views requires comprehensive consideration of response time (acceleration effect), construction cost, and data consistency requirements.
- **Materialized View Definition and Construction Cost Consideration:**
 - The closer the materialized view definition is to the original query, the better the query acceleration effect, but the lower the generality and reusability of the materialization, meaning higher construction costs.
 - The more general the materialized view definition (e.g., without WHERE conditions and more aggregation dimensions), the lower the query acceleration effect, but the better the generality and reusability of the materialization, meaning lower construction costs.

Note

- **Control of Materialized View Quantity:** More materialized views are not necessarily better. Constructing and refreshing materialized views requires resources. Materialized views participate in transparent rewriting, and the CBO cost model needs time to select the optimal materialized view. In theory, the more materialized views, the longer the transparent rewriting time.
- **Regularly Check the Usage Status of Materialized Views:** If not used, they should be deleted in time.
- **Base Table Data Update Frequency:** If the base table data of the materialized view is frequently updated, it may not be suitable to use materialized views, as this will cause the materialized view to frequently become invalid and not usable for transparent rewriting (direct query). If you need to use such materialized views for transparent rewriting, you need to allow a certain timeliness delay in the queried data and can set a `grace_period`. See the applicable introduction of `grace_period` for details. :::

Principles for Choosing Materialized View Refresh Methods

When the following conditions are met, it is recommended to create partitioned materialized views:

- The base table data volume of the materialized view is large, and the base table is a partitioned table.
- The tables used by the materialized view, except for the partitioned table, do not change frequently.
- The definition SQL of the materialized view and the partition field meet the requirements of partition derivation, that is, meet the requirements of partition incremental update. Detailed requirements can be found in [CREATE-ASYNC-MATERIALIZED-VIEW](#)
- The number of partitions in the materialized view is not large, as too many partitions will lead to excessively long partition materialized view construction time.

When some partitions of the materialized view become invalid, transparent rewriting can use the valid partitions of the materialized view UNION ALL base table to return data.

If partitioned materialized views cannot be constructed, you can consider choosing fully refreshed materialized views.

Common Usage of Partitioned Materialized Views

When the materialized view's base table data volume is large and the base table is a partitioned table, if the materialized view's definition SQL and partition fields meet the requirements of partition derivation, this scenario is suitable for building partitioned materialized views. For detailed requirements of partition derivation, refer to [CREATE-ASYNC-MATERIALIZED-VIEW](#) and [Async Materialized View FAQ Building Question 12](#).

The materialized view's partitions are created following the base table's partition mapping, generally having a 1:1 or 1:n relationship with the base table's partitions.

- If the base table's partitions undergo data changes, such as adding partitions or deleting partitions, the corresponding partitions in the materialized view will also become invalid. Invalid partitions cannot be used for transparent rewriting but can be directly queried. When transparent rewriting discovers that the materialized view's partition data is invalid, the invalid partitions will be handled by joining with the base table to respond to queries.

For commands to check materialized view partition status, see viewing materialized view status, mainly using the `show partitions from mv_name` command.

- If non-partitioned tables referenced by the materialized view undergo data changes, it will trigger all partitions of the materialized view to become invalid, preventing the materialized view from being used for transparent rewriting. You need to refresh all partition data of the materialized view using the command `REFRESH MATERIALIZED VIEW mv1 AUTO;`. This command will attempt to refresh all partitions of the materialized view where data has changed.

Therefore, it's generally recommended to place frequently changing data in partitioned tables referenced by the partitioned materialized view, and place infrequently changing dimension tables in non-referenced partition table positions.

- If non-partitioned tables referenced by the materialized view undergo data changes, and the non-partitioned table data is only being added without modifications, you can specify the attribute `excluded_trigger_tables = 'non_partition_table_name1,non_partition_table_name2'` when creating the materialized view. This way, data changes in non-partitioned tables won't invalidate all partitions of the materialized view, and the next refresh will only refresh the invalid partitions of the materialized view corresponding to the partition table.

Transparent rewriting of partitioned materialized views is at the partition granularity. Even if some partitions of the materialized view become invalid, the materialized view can still be used for transparent rewriting. However, if only one partition is queried and that partition's data in the materialized view is invalid, then the materialized view cannot be used for transparent rewriting.

For example:

```
CREATE TABLE IF NOT EXISTS lineitem (
    l_orderkey INTEGER NOT NULL,
    l_partkey INTEGER NOT NULL,
    l_suppkey INTEGER NOT NULL,
    l_linenumber INTEGER NOT NULL,
    l_ordertime DATETIME NOT NULL,
    l_quantity DECIMALV3(15, 2) NOT NULL,
    l_extendedprice DECIMALV3(15, 2) NOT NULL,
    l_discount DECIMALV3(15, 2) NOT NULL,
    l_tax DECIMALV3(15, 2) NOT NULL,
    l_returnflag CHAR(1) NOT NULL,
    l_linestatus CHAR(1) NOT NULL,
    l_shipdate DATE NOT NULL,
    l_commitdate DATE NOT NULL,
    l_receiptdate DATE NOT NULL,
    l_shipinstruct CHAR(25) NOT NULL,
    l_shipmode CHAR(10) NOT NULL,
    l_comment VARCHAR(44) NOT NULL
) DUPLICATE KEY(
    l_orderkey, l_partkey, l_suppkey,
    l_linenumber
) PARTITION BY RANGE(l_ordertime) (
    FROM
        ('2024-05-01') TO ('2024-06-30') INTERVAL 1 DAY
)
DISTRIBUTED BY HASH(l_orderkey) BUCKETS 3;

INSERT INTO lineitem VALUES
(1, 2, 3, 4, '2024-05-01 01:45:05', 5.5, 6.5, 0.1, 8.5, 'o', 'k', '2024-05-01', '2024-05-01', '2024-05-01', 'a', 'b', 'yyyyyyyy'),
(1, 2, 3, 4, '2024-05-15 02:35:05', 5.5, 6.5, 0.15, 8.5, 'o', 'k', '2024-05-15', '2024-05-15', '2024-05-15', 'a', 'b', 'yyyyyyyy'),
(2, 2, 3, 5, '2024-05-25 08:30:06', 5.5, 6.5, 0.2, 8.5, 'o', 'k', '2024-05-25', '2024-05-25', '2024-05-25', 'a', 'b', 'yyyyyyyy'),
(3, 4, 3, 6, '2024-06-02 09:25:07', 5.5, 6.5, 0.3, 8.5, 'o', 'k', '2024-06-02', '2024-06-02', '2024-06-02', 'a', 'b', 'yyyyyyyy'),
(4, 4, 3, 7, '2024-06-15 13:20:09', 5.5, 6.5, 0, 8.5, 'o', 'k', '2024-06-15', '2024-06-15', '2024-06-15', 'a', 'b', 'yyyyyyyy'),
(5, 5, 6, 8, '2024-06-25 15:15:36', 5.5, 6.5, 0.12, 8.5, 'o', 'k', '2024-06-25', '2024-06-25', '2024-06-25', 'a', 'b', 'yyyyyyyy'),
(5, 5, 6, 9, '2024-06-29 21:10:52', 5.5, 6.5, 0.1, 8.5, 'o', 'k', '2024-06-30', '2024-06-30', '2024-06-30', 'a', 'b', 'yyyyyyyy'),
(5, 6, 5, 10, '2024-06-03 22:05:50', 7.5, 8.5, 0.1, 10.5, 'k', 'o', '2024-06-03', '2024-06-03', '2024-06-03', 'c', 'd', 'xxxxxxxx');

CREATE TABLE IF NOT EXISTS partsupp (
```

```

    ps_partkey INTEGER NOT NULL,
    ps_supplekey INTEGER NOT NULL,
    ps_availqty INTEGER NOT NULL,
    ps_supplycost DECIMALV3(15, 2) NOT NULL,
    ps_comment VARCHAR(199) NOT NULL
)
DUPLICATE KEY(ps_partkey, ps_supplekey)
DISTRIBUTED BY HASH(ps_partkey) BUCKETS 3;

INSERT INTO partsupp VALUES
(2, 3, 9, 10.01, 'supply1'),
(4, 3, 9, 10.01, 'supply2'),
(5, 6, 9, 10.01, 'supply3'),
(6, 5, 10, 11.01, 'supply4');

```

In this example, the `o_ordertime` field in the `orders` table is the partition field, with type `DATETIME`, partitioned by day. The main query is based on a “day” granularity:

```

SELECT
    l_linestatus,
    sum(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    ps_partkey
FROM
    lineitem
    LEFT JOIN partsupp ON l_partkey = ps_partkey
    and l_supplekey = ps_supplekey
WHERE
    date_trunc(l_ordertime, 'day') <= DATE '2024-05-25'
    AND date_trunc(l_ordertime, 'day') >= DATE '2024-05-05'
GROUP BY
    l_linestatus,
    ps_partkey;

```

To avoid refreshing too many partitions each time in the materialized view, the partition granularity can be consistent with the base table `orders`, also partitioning by “day”.

The materialized view’s definition SQL can use “day” granularity and aggregate data by “day”:

```

CREATE MATERIALIZED VIEW rollup_partition_mv
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
partition by(order_date)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    sum(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    ps_partkey,
    date_trunc(l_ordertime, 'day') as order_date
FROM
    lineitem
    LEFT JOIN partsupp ON l_partkey = ps_partkey
    and l_supplekey = ps_supplekey
GROUP BY
    l_linestatus,

```

```
ps_partkey,  
date_trunc(l_ordertime, 'day');
```

Creating Partitioned Materialized Views with UNION ALL

Currently, Doris has a limitation where partitioned materialized view definitions cannot contain UNION ALL clauses. To create a materialized view that includes UNION ALL, you can use the following approach: For each input part of the UNION ALL, attempt to create a partitioned materialized view, and then create a regular view for the entire UNION ALL result set.

For example: The materialized view definition below contains a UNION ALL clause, which cannot be directly used to create a partitioned materialized view.

```
SELECT  
  l_linestatus,  
  sum(  
    l_extendedprice * (1 - l_discount)  
  ) AS revenue,  
  ps_partkey,  
  date_trunc(l_ordertime, 'day') as order_date  
FROM  
  lineitem  
LEFT JOIN partsupp ON l_partkey = ps_partkey  
and l_suppkey = ps_suppkey  
GROUP BY  
  l_linestatus,  
  ps_partkey,  
  date_trunc(l_ordertime, 'day')  
UNION ALL  
SELECT  
  l_linestatus,  
  l_extendedprice,  
  ps_partkey,  
  date_trunc(l_ordertime, 'day') as order_date  
FROM  
  lineitem  
LEFT JOIN partsupp ON l_partkey = ps_partkey  
and l_suppkey = ps_suppkey;
```

You can split the above SQL statement into two parts and create two partitioned materialized views separately.

```
CREATE MATERIALIZED VIEW union_sub_mv1  
BUILD IMMEDIATE REFRESH AUTO ON MANUAL  
partition by(order_date)  
DISTRIBUTED BY RANDOM BUCKETS 2  
AS  
SELECT  
  l_linestatus,  
  sum(  
    l_extendedprice * (1 - l_discount)  
  ) AS revenue,  
  ps_partkey,  
  date_trunc(l_ordertime, 'day') as order_date  
FROM  
  lineitem
```

```
LEFT JOIN partsupp ON l_partkey = ps_partkey
and l_suppkey = ps_suppkey
GROUP BY
l_linestatus,
ps_partkey,
date_trunc(l_ordertime, 'day');
```

```
CREATE MATERIALIZED VIEW union_sub_mv2
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
partition by(order_date)
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
l_linestatus,
l_extendedprice,
ps_partkey,
date_trunc(l_ordertime, 'day') as order_date
FROM
lineitem
LEFT JOIN partsupp ON l_partkey = ps_partkey
and l_suppkey = ps_suppkey;
```

Then create a regular view that performs UNION ALL on the result sets of the two partitioned materialized views. This view (union_all_view) can be exposed externally.

```
CREATE VIEW union_all_view
AS
SELECT *
FROM
union_sub_mv1
UNION ALL
SELECT *
FROM
union_sub_mv2;
```

Partitioned Materialized Views Retaining Only Recent Partition Data

Note

This feature has been supported since Apache Doris version 2.1.1.

Materialized views can be configured to retain data only from the most recent partitions, automatically deleting expired partition data during each refresh. This can be achieved by setting the following properties for the materialized view: `partition_sync_limit`, `partition_sync_time_unit`, and `partition_sync_date_format`.

`partition_sync_limit`: When the base table's partition field is time-based, this property configures the synchronization range for base table partitions, working in conjunction with `partition_sync_time_unit`. For example, setting it to 3 with `partition_sync_time_unit` as DAY means only partitions and data from the last 3 days of the base table will be synchronized.

`partition_sync_time_unit`: The time unit for partition refresh, supporting DAY/MONTH/YEAR (default is DAY).

`partition_date_format`: When the base table's partition field is a string type, this property sets the date format if you want to use the `partition_sync_limit` capability.

Example: The materialized view defined below will only retain data from the last 3 days. If there's no data in the recent 3 days, querying this materialized view directly will return no results.

```
CREATE MATERIALIZED VIEW latest_partition_mv
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
PARTITION BY(order_date)
DISTRIBUTED BY RANDOM BUCKETS 2
PROPERTIES (
  "partition_sync_limit" = "3",
  "partition_sync_time_unit" = "DAY",
  "partition_date_format" = "yyyy-MM-dd"
)
AS
SELECT
  l_linestatus,
  sum(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  ps_partkey,
  date_trunc(l_ordertime, 'day') as order_date
FROM
  lineitem
LEFT JOIN partsupp ON l_partkey = ps_partkey
AND l_suppkey = ps_suppkey
GROUP BY
  l_linestatus,
  ps_partkey,
  date_trunc(l_ordertime, 'day');
```

How to Use Materialized Views to Accelerate Queries

To use materialized views for query acceleration, first check the profile file to find the operation that consumes the most time in a query, which usually appears in Join, Aggregate, Filter, or Calculated Expressions.

For Join, Aggregate, Filters, and Calculated Expressions, building materialized views can help accelerate queries. If a Join operation in a query consumes a large amount of computing resources while Aggregate consumes relatively fewer resources, you can build materialized views targeting the Join operation.

Next, we'll explain in detail how to build materialized views for these four operations:

1. For Join

You can extract common table join patterns used in queries to build materialized views. If transparent rewriting uses this materialized view, it can save Join computation. Remove the Filters from the query to create a more general Join materialized view.

2. For Aggregate

It is recommended to use low-cardinality fields as dimensions when building materialized views. If the dimensions are related, the number after aggregation can be reduced as much as possible.

For example, with table t1, if the original table has 1,000,000 records, and the SQL query has group by a, b, c. If the cardinality of a, b, c is 100, 50, and 15 respectively, then the aggregated data would be around 75,000, indicating that this materialized view is effective. If a, b, c are correlated, the amount of aggregated data will be further reduced.

If a, b, c have high cardinality, it will cause the aggregated data to expand rapidly. If the aggregated data is more than the original table data, this scenario might not be suitable for building materialized views. For example, if c's cardinality is 3,500, then the aggregated data would be around 17,000,000, much larger than the original table data, making the performance acceleration benefit of building such a materialized view low.

The aggregation granularity of the materialized view should be finer than the query, meaning the aggregation dimensions of the materialized view should include the query's aggregation dimensions to provide the data needed by the query. The query may not write Group By, and similarly, the aggregation functions of the materialized view should include the query's aggregation functions.

Taking aggregate query acceleration as an example:

Query 1:

```
SELECT
  l_linestatus,
  sum(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_shippriority
FROM
  orders
  LEFT JOIN lineitem ON l_orderkey = o_orderkey
WHERE
  o_orderdate <= DATE '2024-06-30'
  AND o_orderdate >= DATE '2024-05-01'
GROUP BY
  l_linestatus,
  o_shippriority,
  l_partkey;
```

Query 2:

```
SELECT
  l_linestatus,
  sum(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_shippriority
FROM
  orders
  LEFT JOIN lineitem ON l_orderkey = o_orderkey
WHERE
  o_orderdate <= DATE '2024-06-30'
  AND o_orderdate >= DATE '2024-05-01'
GROUP BY
  l_linestatus,
  o_shippriority,
  l_suppkey;
```

Based on the above two SQL queries, we can build a more general materialized view that includes Aggregate. In this materialized view, we include both l_partkey and l_suppkey as group by dimensions for aggregation, and use o_orderdate as a filter condition. Note that o_orderdate is not only used in the materialized view's condition compensation but also needs to be included in the materialized view's aggregation group by dimensions.

After building the materialized view this way, both Query 1 and Query 2 can hit this materialized view. The materialized view definition is as follows:

```
CREATE MATERIALIZED VIEW common_agg_mv
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    sum(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    o_shippriority,
    l_suppkey,
    l_partkey,
    o_orderdate
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey
GROUP BY
    l_linestatus,
    o_shippriority,
    l_suppkey,
    l_partkey,
    o_orderdate;
```

3. For Filter

If filters on the same fields frequently appear in queries, adding corresponding Filters in the materialized view can reduce the amount of data in the materialized view, thereby improving the performance when queries hit the materialized view.

Note that the materialized view should have fewer Filters than those appearing in queries, and the query's Filters should include the materialized view's Filters. For example, if the query is $a > 10$ and $b > 5$, the materialized view can have no Filter, or if it has Filters, it should filter on a and b with a larger data range than the query, such as $a > 5$ and $b > 5$, $b > 0$, or just $a > 5$.

4. For Calculated Expressions

Taking examples like case when and string processing functions, these expression calculations are very performance-intensive. If these can be pre-calculated in the materialized view, using the pre-calculated materialized view through transparent rewriting can improve query performance.

It is recommended that the number of columns in the materialized view should not be too many. If a query uses multiple fields, you should build corresponding materialized views for different columns based on the initial SQL pattern grouping, avoiding too many columns in a single materialized view.

Usage Scenarios

Scenario One: Query Acceleration

In BI reporting scenarios or other acceleration scenarios, users are sensitive to query response times and typically require results to be returned in seconds. Queries usually involve multiple table joins followed by aggregate calculations, which consume significant computing resources and sometimes make it difficult to guarantee timeliness. Asynchronous materialized views can handle this well, supporting both direct queries and transparent rewriting, where the optimizer automatically selects the optimal materialized view to respond to requests based on rewriting algorithms and cost models.

Use Case 1: Multi-table Join Aggregate Query Acceleration

Building more general materialized views can accelerate multi-table join aggregate queries.

Taking the following three query SQLs as examples:

Query 1:

```
SELECT
  l_linestatus,
  l_extendedprice * (1 - l_discount),
  o_shippriority
FROM
  orders
  LEFT JOIN lineitem ON l_orderkey = o_orderkey
WHERE
  o_orderdate <= DATE '2024-06-30'
  AND o_orderdate >= DATE '2024-05-01';
```

Query 2:

```
SELECT
  l_linestatus,
  sum(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_orderdate,
  o_shippriority
FROM
  orders
  LEFT JOIN lineitem ON l_orderkey = o_orderkey
WHERE
  o_orderdate <= DATE '2024-06-30'
  AND o_orderdate >= DATE '2024-05-01'
GROUP BY
  l_linestatus,
  o_orderdate,
  o_shippriority;
```

Query 3:

```
SELECT
  l_linestatus,
  l_extendedprice * (1 - l_discount),
```

```

    o_orderdate,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;

```

For the above queries, we can build the following materialized view to satisfy all the above queries.

The materialized view definition removes the filter conditions from Query 1 and Query 2 to get a more general Join, and pre-calculates the expression $l_extendedprice * (1 - l_discount)$, so when queries hit the materialized view, it can save expression calculation:

```

CREATE MATERIALIZED VIEW common_join_mv
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    l_extendedprice * (1 - l_discount),
    o_orderdate,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;

```

If the above materialized view cannot meet the acceleration performance requirements of Query 2, we can build an aggregate materialized view. To maintain generality, we can remove the filter condition on the `o_orderdate` field:

```

CREATE MATERIALIZED VIEW target_agg_mv
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
DISTRIBUTED BY RANDOM BUCKETS 2
AS
SELECT
    l_linestatus,
    sum(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    o_orderdate,
    o_shippriority
FROM
    orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey
GROUP BY
    l_linestatus,
    o_orderdate,
    o_shippriority;

```

Use Case 2: Log Query Acceleration

In log query acceleration scenarios, it is recommended not to limit yourself to using only asynchronous materialized views; they can be combined with synchronous materialized views.

Generally, the base table is a partitioned table, mostly partitioned by hour, with single-table aggregate queries, and filter conditions are usually based on time and some flag bits. Sometimes when query

response speed cannot meet requirements, synchronous materialized views can usually be built for acceleration.

For example, the base table definition might be as follows:

```
CREATE TABLE IF NOT EXISTS test (  
  `app_name` VARCHAR(64) NULL COMMENT 'identifier',  
  `event_id` VARCHAR(128) NULL COMMENT 'identifier',  
  `decision` VARCHAR(32) NULL COMMENT 'enum value',  
  `time` DATETIME NULL COMMENT 'query time',  
  `id` VARCHAR(35) NOT NULL COMMENT 'od',  
  `code` VARCHAR(64) NULL COMMENT 'identifier',  
  `event_type` VARCHAR(32) NULL COMMENT 'event type'  
)  
DUPLICATE KEY(app_name, event_id)  
PARTITION BY RANGE(time)  
(  
  FROM ("2024-07-01 00:00:00") TO ("2024-07-15 00:00:00") INTERVAL 1 HOUR  
)  
DISTRIBUTED BY HASH(event_id)  
BUCKETS 3;
```

The materialized view can aggregate data by minute, which can also achieve a certain aggregation effect. For example:

```
CREATE MATERIALIZED VIEW sync_mv  
AS  
SELECT  
  decision,  
  code,  
  app_name,  
  event_id,  
  event_type,  
  date_trunc(time, 'minute'),  
  DATE_FORMAT(  
    `time`, '%Y-%m-%d'  
  ),  
  cast(FLOOR(MINUTE(time) / 15) as decimal(9, 0)),  
  count(id) as cnt  
from  
  test  
group by  
  code,  
  app_name,  
  event_id,  
  event_type,  
  date_trunc(time, 'minute'),  
  decision,  
  DATE_FORMAT(time, '%Y-%m-%d'),  
  cast(FLOOR(MINUTE(`time`) / 15) as decimal(9, 0));
```

The query statement might be as follows:

```
SELECT  
  decision,  
  CONCAT(  
    CONCAT(  
      DATE_FORMAT(  
        `time`, '%Y-%m-%d'
```

```

    ),
    '',
    LPAD(
        cast(FLOOR(MINUTE(`time`) / 15) as decimal(9, 0)) * 15,
        5,
        '00'
    ),
    ':00'
)
) as time,
count(id) as cnt
from
test
where
date_trunc(time, 'minute') BETWEEN '2024-07-02 18:00:00'
AND '2024-07-03 20:00:00'
group by
decision,
DATE_FORMAT(
`time`, "%Y-%m-%d"
),
cast(FLOOR(MINUTE(`time`) / 15) as decimal(9, 0));

```

Scenario Two: Data Modeling (ETL)

Data analysis work often requires joining and aggregating multiple tables, a process that typically involves complex and frequently repeated queries. These types of queries may lead to high query latency or high resource consumption issues. However, if using asynchronous materialized views to build layered data models, these problems can be well avoided. You can create higher-level materialized views based on existing materialized views (supported since version 2.1.3), flexibly meeting different requirements.

Different levels of materialized views can be set with their own trigger methods, for example:

- The first layer of materialized views can be set to refresh periodically, and the second layer set to trigger refresh. This way, when the first layer of materialized views completes refreshing, it will automatically trigger the refresh of the second layer materialized views.
- If each layer of materialized views is set to refresh periodically, then when the second layer materialized view refreshes, it won't consider whether the first layer's materialized view data is synchronized with the base table, it will just process the first layer's materialized view data and synchronize it to the second layer.

Next, we'll use the TPC-H dataset to illustrate the application of asynchronous materialized views in data modeling, taking the analysis of monthly order quantities and profits by region and country as an example:

Original query (without using materialized views):

```

SELECT
n_name,
date_trunc(o.o_orderdate, 'month') as month,
count(distinct o.o_orderkey) as order_count,
sum(l.l_extendedprice * (1 - l.l_discount)) as revenue
FROM orders o
JOIN lineitem l ON o.o_orderkey = l.l_orderkey
JOIN customer c ON o.o_custkey = c.c_custkey
JOIN nation n ON c.c_nationkey = n.n_nationkey

```

```
JOIN region r ON n.n_regionkey = r.r_regionkey
GROUP BY n_name, month;
```

Using asynchronous materialized views for layered modeling:

Build DWD layer (detailed data), process order detail wide table

```
CREATE MATERIALIZED VIEW dwd_order_detail
BUILD IMMEDIATE REFRESH AUTO ON COMMIT
DISTRIBUTED BY RANDOM BUCKETS 16
AS
select
o.o_orderkey,
o.o_custkey,
o.o_orderstatus,
o.o_totalprice,
o.o_orderdate,
c.c_name,
c.c_nationkey,
n.n_name as nation_name,
r.r_name as region_name,
l.l_partkey,
l.l_quantity,
l.l_extendedprice,
l.l_discount,
l.l_tax
from orders o
join customer c on o.o_custkey = c.c_custkey
join nation n on c.c_nationkey = n.n_nationkey
join region r on n.n_regionkey = r.r_regionkey
join lineitem l on o.o_orderkey = l.l_orderkey;
```

Build DWS layer (summary data), perform daily order summary

```
CREATE MATERIALIZED VIEW dws_daily_sales
BUILD IMMEDIATE REFRESH AUTO ON COMMIT
DISTRIBUTED BY RANDOM BUCKETS 16
AS
select
date_trunc(o_orderdate, 'month') as month,
nation_name,
region_name,
bitmap_union(to_bitmap(o_orderkey)) as order_count,
sum(l_extendedprice * (1 - l_discount)) as net_revenue
from dwd_order_detail
group by
date_trunc(o_orderdate, 'month'),
nation_name,
region_name;
```

The optimized query using materialized views is as follows:

```
SELECT
nation_name,
month,
bitmap_union_count(order_count),
sum(net_revenue) as revenue
FROM dws_daily_sales
GROUP BY nation_name, month;
```

Scenario Three: Lake-Warehouse Integration Federated Data Query

In modern data architectures, enterprises often adopt a lake-warehouse integration design to balance data storage costs and query performance. Under this architecture, two key challenges are frequently encountered:

- Limited Query Performance: When frequently querying data from data lakes, performance may be affected by network latency and third-party services, leading to query delays and impacting user experience.
- Complexity of Data Layer Modeling: In the data flow and transformation process from data lake to real-time data warehouse, complex ETL processes are usually required, which increases maintenance costs and development difficulty.

Using Doris asynchronous materialized views can effectively address these challenges:

- Transparent Rewriting Accelerates Queries: Materialize commonly used data lake query results into Doris internal storage, using transparent rewriting to effectively improve query performance.
- Simplify Layer Modeling: Support creating materialized views based on tables in the data lake, enabling convenient transformation from data lake to real-time data warehouse, greatly simplifying the data modeling process.

For example, using Hive:

Create Catalog based on Hive, using TPC-H dataset

```
CREATE CATALOG hive_catalog PROPERTIES (  
  'type'='hms', -- hive meta store address  
  'hive.metastore.uris' = 'thrift://172.21.0.1:7004'  
);
```

Create materialized view based on Hive Catalog

```
-- Materialized views can only be created on internal catalog, switch to internal catalog  
switch internal;  
create database hive_mv_db;  
use hive_mv_db;  
  
CREATE MATERIALIZED VIEW external_hive_mv  
BUILD IMMEDIATE REFRESH AUTO ON MANUAL  
DISTRIBUTED BY RANDOM BUCKETS 12  
AS  
SELECT  
  n_name,  
  o_orderdate,  
  sum(l_extendedprice * (1 - l_discount)) AS revenue  
FROM  
  customer,  
  orders,  
  lineitem,  
  supplier,  
  nation,  
  region  
WHERE  
  c_custkey = o_custkey  
  AND l_orderkey = o_orderkey  
  AND l_suppkey = s_suppkey  
  AND c_nationkey = s_nationkey  
  AND s_nationkey = n_nationkey  
  AND n_regionkey = r_regionkey  
  AND r_name = 'ASIA'  
GROUP BY
```

```
n_name,  
o_orderdate;
```

Run the following query, which will automatically use the materialized view for acceleration through transparent rewriting.

```
SELECT  
n_name,  
sum(l_extendedprice * (1 - l_discount)) AS revenue  
FROM  
customer,  
orders,  
lineitem,  
supplier,  
nation,  
region  
WHERE  
c_custkey = o_custkey  
AND l_orderkey = o_orderkey  
AND l_suppkey = s_suppkey  
AND c_nationkey = s_nationkey  
AND s_nationkey = n_nationkey  
AND n_regionkey = r_regionkey  
AND r_name = 'ASIA'  
AND o_orderdate >= DATE '1994-01-01'  
AND o_orderdate < DATE '1994-01-01' + INTERVAL '1' YEAR  
GROUP BY  
n_name  
ORDER BY  
revenue DESC;
```

Note

Doris currently cannot detect data changes in external tables other than Hive. When external table data is inconsistent, using materialized views may result in data inconsistency. The following switch indicates: whether materialized views participating in transparent rewriting are allowed to include external tables, default false. If you accept data inconsistency or ensure external table data consistency through periodic refresh, you can set this switch to true. Set whether materialized views containing external tables can be used for transparent rewriting, default not allowed, if you can accept data inconsistency or can ensure data consistency yourself, you can enable

```
SET materialized_view_rewrite_enable_contain_external_table = true;
```

If the materialized view is in MaterializedViewRewriteSuccessButNotChose status, it means the rewrite was successful but the plan was not chosen by CBO, possibly due to incomplete statistics of external tables. Enable getting row count from file list for statistics

```
SET enable_get_row_count_from_file_list = true;
```

View external table statistics to confirm if they are complete

```
SHOW TABLE STATS external_table_name;
```

Scenario Four: Improving Write Efficiency, Reducing Resource Contention

In high-throughput data write scenarios, system stability and efficient data processing are equally important. Through the flexible refresh strategies of asynchronous materialized views, users can choose appropriate refresh methods based on specific scenarios, thereby reducing write pressure and avoiding resource contention.

Compared to synchronous materialized views, asynchronous materialized views provide three flexible refresh strategies: manual trigger, trigger-based, and periodic trigger. Users can choose suitable refresh strategies based on scenario requirements. When base table data changes, it won't immediately trigger materialized view refresh, and delayed refresh helps reduce resource pressure, effectively avoiding write resource contention.

As shown below, the chosen refresh method is periodic refresh, refreshing every 2 hours. When orders and lineitem import data, it won't immediately trigger materialized view refresh.

```
CREATE MATERIALIZED VIEW common_schedule_join_mv
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 2 HOUR
DISTRIBUTED BY RANDOM BUCKETS 16
AS
SELECT
  l_linestatus,
  l_extendedprice * (1 - l_discount),
  o_orderdate,
  o_shippriority
FROM
  orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;
```

Transparent rewriting can rewrite query SQL and achieve query acceleration, while also being able to rewrite import SQL to improve import efficiency. Starting from version 2.1.6, when materialized view and base table data are strongly consistent, DML operations like Insert Into or Insert Overwrite can be transparently rewritten, which significantly improves performance for data import scenarios.

1. Create target table for Insert Into data

```
CREATE TABLE IF NOT EXISTS target_table (
  orderdate      DATE NOT NULL,
  shippriority    INTEGER NOT NULL,
  linestatus      CHAR(1) NOT NULL,
  sale           DECIMALV3(15,2) NOT NULL
)
DUPLICATE KEY(orderdate, shippriority)
DISTRIBUTED BY HASH(shippriority) BUCKETS 3;
```

2. common_schedule_join_mv

```
CREATE MATERIALIZED VIEW common_schedule_join_mv
BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 2 HOUR
DISTRIBUTED BY RANDOM BUCKETS 16
AS
SELECT
  l_linestatus,
  l_extendedprice * (1 - l_discount),
  o_orderdate,
```

```
o_shippriority
FROM
orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;
```

Import statement before rewriting:

```
INSERT INTO target_table
SELECT
o_orderdate,
o_shippriority,
l_linestatus,
l_extendedprice * (1 - l_discount)
FROM
orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey;
```

After transparent rewriting, the statement becomes:

```
INSERT INTO target_table
SELECT *
FROM common_schedule_join_mv;
```

Note that: If the DML operation involves external tables whose data changes cannot be detected, transparent rewriting may cause the latest base table data to not be imported into the target table in real-time. If users can accept data inconsistency or can ensure data consistency themselves, they can enable the following switch:

For DML, when the materialized view contains external tables whose data cannot be detected in real-time, whether to enable materialized view transparent rewriting based on structure information, default disabled

```
SET enable_dml_materialized_view_rewrite_when_base_table_unawareness = true;
```

Use Advice

Overview

Asynchronous materialized views improve query performance by precomputing and storing query results, but each refresh may incur significant overhead. This document provides usage recommendations for asynchronous materialized views.

For the refresh principles of materialized views, refer to: [Refresh Principles](#)

Recommended Usage Scenarios

Recommended Scenarios

Complex Aggregation Queries

- **Scenario:** Queries involving multi-table joins, complex aggregate functions (e.g., SUM, AVG, COUNT), or window functions
- **Advantage:** Avoids recomputing complex logic during each execution

Reporting

- **Scenario:** Reports requiring consistent snapshots at fixed time points (e.g., daily midnight)
- **Advantage:** Ensures all users see data from the same point in time

Computation-Intensive Analysis

- **Scenario:** Analytical queries involving complex mathematical calculations or data transformations, such as customer lifetime value calculations or predictive modeling
- **Advantage:** Precomputes results to reduce runtime resource consumption

Star/Snowflake Schemas in Data Warehouses

- **Scenario:** Fact tables joined with multiple dimension tables, e.g., sales fact tables joined with product, time, and region dimension tables
- **Advantage:** Pre-materializes join results to accelerate analytical queries

Data Lake Acceleration

- **Scenario:** Queries on data lakes may slow down due to network latency and object storage throughput limitations
- **Advantage:** Leverages Doris's local storage advantages to accelerate data lake analysis

Data Warehouse Layering

- **Scenario:** Base tables contain large amounts of raw data, and queries require complex ETL operations
- **Advantage:** Implements data warehouse layering by building multi-level asynchronous materialized views

Not Recommended Scenarios

Frequently Updated Base Tables

- **Scenario:** Source table data changes very frequently (e.g., multiple updates per minute)
- **Issue:** Asynchronous materialized views struggle to stay synchronized, and refresh costs are too high. Consider periodic refreshes instead.

Simple Queries

- **Scenario:** Queries involving only single-table scans or simple filtering
- **Issue:** The benefits of asynchronous materialized views cannot offset the refresh costs

Scenarios Requiring Real-Time (1–5 Minute Freshness) Data

- **Scenario:** Business requirements demand the latest data
- **Issue:** Asynchronous materialized views introduce data latency

Small Source Tables

- **Scenario:** Base tables contain only a small number of records (e.g., a few hundred rows)
- **Issue:** The optimization effect of asynchronous materialized views is negligible

Refresh Strategy Recommendations

Asynchronous materialized views offer three primary refresh strategies, each suited to different business scenarios and data characteristics. Choosing the right strategy is critical for balancing data freshness and system performance.

Detailed Refresh Strategies

Manual Refresh

How It Works: - Triggered explicitly by user commands or external system scheduling

Applicable Scenarios: - Reporting systems with low real-time data requirements - Historical data analysis in data warehouses - Scenarios requiring synchronization with specific business processes - Large-scale data refreshes requiring coordinated system resources

Pros and Cons: - Pros: Full control over refresh timing, avoiding peak business hours - Cons: Requires additional scheduling management and fault tolerance to prevent external loops from continuously triggering

refreshes

Scheduled Refresh

How It Works: - Automatically refreshes at fixed intervals - Minimum time unit: minutes - Can specify the start time for the first task run

Applicable Scenarios: - Periodic business metric monitoring - Tiered data pipelines - Time-sensitive reporting systems - Source data with regular fluctuations

Pros and Cons: - Pros: Scheduled data processing with predictable data latency - Cons: Limited data freshness; refresh sequences for related views require manual orchestration

Configuration Constraints:

Avoid configuring all materialized views for high-frequency scheduled refreshes to achieve near-real-time results, as this may: - Continuously occupy system resources - Cause refresh jobs to compete for resources - Frequent partition/tablet operations may impose heavy pressure on BEs

Trigger-Based Refresh

How It Works: - Automatically triggers refreshes when base table data changes

Applicable Scenarios: - Upper-layer views in a multi-level materialized view architecture - Scenarios where base tables change infrequently

Pros and Cons: - Pros: High data freshness and automation - Cons: May cause refresh storms and unpredictable system load

Configuration Constraints:

Avoid using trigger-based refreshes for foundational materialized views unless: - Base table refresh frequency is known to be low (e.g., changes every few tens of minutes)

Combined Refresh Strategy Recommendations

Layered Strategy

- **Foundation Layer:** Scheduled refresh (e.g., hourly)
- **Intermediate Layer:** Scheduled or trigger-based refresh
- **Presentation Layer:** Trigger-based or manual refresh

Business Criticality Tiering

- **Critical Real-Time Business Data:** Not recommended for asynchronous materialized views
- **Regular Analytical Data:** Scheduled refresh (daily/hourly)
- **Historical/Archived Data:** Manual refresh

Data Change Frequency Adaptation

- **High-Frequency Changes:** Scheduled refresh (longer intervals) or manual refresh
- **Low-Frequency Changes:** Trigger-based refresh or short-interval scheduled refresh
- **Bulk Changes:** Manual refresh after changes

Refresh Frequency Recommendations

These are general guidelines; actual settings should consider system resources, the number of materialized views, and other business resource usage.

| Actual Refresh Time | Recommended Refresh Frequency |
|---------------------|-------------------------------|
| < 15s | ≥ 5 minutes |
| < 10 minutes | ≥ 1 hour |
| < 1 hour | ≥ 1 day |

Key Considerations for Asynchronous Materialized Views

1. **Monitoring:** After deploying materialized views, monitor system performance via [metrics](#). Additional metrics for asynchronous materialized views will be exposed in the future. Currently, use [tasks](#) to check task count, execution status, and duration.
2. **Planning:** Plan the number of materialized views, refresh frequency, and the cluster's maximum computational capacity. Avoid “creating materialized views without maintaining them”—they are essentially enhanced ETL computations and require maintenance like traditional ETL.
3. **Resource Isolation:** Materialized views are data computation tasks. Implement resource isolation as needed.

FAQ

Build and Refresh

Q1: How does Doris determine which partitions need to be refreshed for a materialized view?

Doris internally calculates the partition correspondence between the materialized view and the base tables and records the version of the base table partitions used by the materialized view after the last successful refresh. For example, if materialized view, mv1 is created from base tables t1 and t2 and is partitioned based on t1.

Assuming partition p202003 of mv1 corresponds to partitions p20200301 and p20200302 of base table t1, after refreshing p202003, Doris will record partitions p20200301 and p20200302, along with the current version of table t2.

During the next refresh, Doris checks if the versions of p20200301, p20200302, and t2 have changed. If any of them have changed, it indicates that p202003 needs to be refreshed.

Alternatively, if changes to t2 can be accepted without triggering a refresh of mv1, the `excluded_trigger_tables` property of the materialized view can be used to configure this.

Q2: What can be done if a materialized view consumes too many resources, impacting other business operations?

You can control the resources allocated to materialized view refresh tasks by specifying a [workload_group](#) through the materialized view's properties.

It's important to note that if the memory allocation is too small and the refresh of a single partition requires more memory, the task may fail. This trade-off should be carefully considered based on business requirements.

Q3: Can a new materialized view be created based on an existing materialized view?

Yes, this is supported starting from Doris 2.1.3. However, each materialized view employs its own refresh logic when updating data. For example, if mv2 is based on mv1, which in turn is based on t1, the synchronization between mv1 and t1 will not be considered during the refresh of mv2.

Q4: Which external tables are supported by Doris?

All external tables supported by Doris can be used to create materialized views. However, only Hive currently supports partition refreshes, with support for other types planned in the future.

Q5: The materialized view displays the same data as Hive, but in reality, they are inconsistent.

A materialized view guarantees consistency only with the results obtained through the Catalog. Since the Catalog contains metadata and data caching, to ensure that the materialized view and Hive data remain consistent, you may need to refresh the Catalog using methods such as `REFRESH CATALOG` to synchronize the Catalog data with Hive.

Q6: Does materialized view support schema change?

No, schema changes are not supported because the column attributes of a materialized view are derived from the SQL definition of the materialized view itself. Explicit custom modifications are not allowed.

Q7: Can the base tables used by materialized views undergo schema changes?

Yes, schema changes are allowed. However, after the change, the status of the materialized views that use this base table will change from NORMAL to SCHEMA_CHANGE, at which point the materialized view cannot be used for transparent rewriting but direct queries to the materialized view will not be affected. If the next refreshing task of the materialized view is successful, its status will change back to NORMAL.

Q8: Can tables with the primary key model be used to create materialized views?

There are no restrictions on the data model of the base tables for materialized views. However, the materialized view itself can only be of the detailed model.

Q9: Can indexes be created on materialized views?

Yes.

Q10: Does the materialized view lock tables during refresh?

Table locking occurs for a brief period during the refresh but does not continuously occupy table locks (almost equivalent to the locking time during data import).

Q11: Is the materialized view suitable for near-real-time scenarios?

Not particularly. The minimum unit for refreshing materialized views is the partition, which can consume significant resources for large data volumes and lacks real-time capabilities. Consider using synchronous materialized views or other methods instead.

Q12: Error encountered when building a partitioned materialized view

Error Message:

```
Unable to find a suitable base table for partitioning
```

This error typically indicates that the SQL definition of the materialized view and the choice of partitioning fields do not allow incremental partition updates, resulting in an error during the creation of the partitioned materialized view.

- For incremental partition updates, the materialized view's SQL definition and partitioning field selection must meet specific requirements. See [Materialized View Refresh Modes](#) for details.
- The latest code can indicate the reason for partition build failure, with error summaries and descriptions provided in Appendix 2.

Example:

```

CREATE TABLE IF NOT EXISTS orders (
  o_orderkey INTEGER NOT NULL,
  o_custkey INTEGER NOT NULL,
  o_orderstatus CHAR(1) NOT NULL,
  o_totalprice DECIMALV3(15, 2) NOT NULL,
  o_orderdate DATE NOT NULL,
  o_orderpriority CHAR(15) NOT NULL,
  o_clerk CHAR(15) NOT NULL,
  o_shippriority INTEGER NOT NULL,
  o_comment VARCHAR(79) NOT NULL
) DUPLICATE KEY(o_orderkey, o_custkey) PARTITION BY RANGE(o_orderdate) (
  FROM
    ('2024-05-01') TO ('2024-06-30') INTERVAL 1 DAY
) DISTRIBUTED BY HASH(o_orderkey) BUCKETS 3 PROPERTIES ("replication_num" = "1");

CREATE TABLE IF NOT EXISTS lineitem (
  l_orderkey INTEGER NOT NULL,
  l_partkey INTEGER NOT NULL,
  l_suppkey INTEGER NOT NULL,
  l_linenummer INTEGER NOT NULL,
  l_quantity DECIMALV3(15, 2) NOT NULL,
  l_extendedprice DECIMALV3(15, 2) NOT NULL,
  l_discount DECIMALV3(15, 2) NOT NULL,
  l_tax DECIMALV3(15, 2) NOT NULL,
  l_returnflag CHAR(1) NOT NULL,
  l_linestatus CHAR(1) NOT NULL,
  l_shipdate DATE NOT NULL,
  l_commitdate DATE NOT NULL,
  l_receiptdate DATE NOT NULL,
  l_shipinstruct CHAR(25) NOT NULL,
  l_shipmode CHAR(10) NOT NULL,
  l_comment VARCHAR(44) NOT NULL
) DUPLICATE KEY(
  l_orderkey, l_partkey, l_suppkey,
  l_linenummer
) DISTRIBUTED BY HASH(l_orderkey) BUCKETS 3 PROPERTIES ("replication_num" = "1");

```

The materialized view definition below allows for incremental partition updates if `orders.o_orderdate` is chosen as the partitioning field for the materialized view. Conversely, using `lineitem.l_shipdate` would not enable incremental updates.

Reason:

1. `lineitem.l_shipdate` is not a partitioning column of the base table, and `lineitem` does not have a partitioning column defined.
2. `lineitem.l_shipdate` is the column that generates null values during the outer join operation.

```

CREATE MATERIALIZED VIEW mv_1 BUILD IMMEDIATE REFRESH AUTO ON MANUAL partition by(o_orderdate) DISTRIBUTED BY
RANDOM BUCKETS 2 PROPERTIES ('replication_num' = '1') AS
SELECT
  l_linestatus,
  sum(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_orderdate,
  o_shippriority
FROM
  orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey

```

```
WHERE
  o_orderdate <= DATE '2024-06-30'
AND o_orderdate >= DATE '2024-05-01'
GROUP BY
  l_linestatus,
  o_orderdate,
  o_shippriority;
```

Q13: Error encountered when creating a materialized view

Error Message:

```
ERROR 1105 (HY000): errCode = 2, detailMessage = Syntax error in line 1:
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
```

Reasons may be:

1. The statement for creating an asynchronous materialized view is only supported by the new optimizer. Ensure you are using the new optimizer:

```
SET enable_nereids_planner = true;
```

2. There may be a typographical error in the refresh keywords or a syntax error in the SQL definition of the materialized view. Check the SQL definition and creation statement for the materialized view for correctness.

Q14: After the materialized view is refreshed successfully, there is still no data

The materialized view determines whether the data needs to be updated based on its ability to retrieve version information from the base table or base table partitions.

When encountering data lakes that currently do not support retrieving version information, such as JDBC Catalog, the refresh process will assume that the materialized view does not need to be updated. Therefore, when creating or refreshing a materialized view, you should specify complete instead of auto.

For the progress of materialized view support for data lakes, please refer to [Data Lake Support Status](#).

Q15: Why is my partitioned materialized view always fully refreshed?

The incremental refresh of a materialized view's partitions depends on version information from the base table partitions. If data in the base table partitions changes since the last refresh, the materialized view will refresh those corresponding partitions. If your partitioned materialized view is being fully refreshed, the possible reasons are:

Changes occurred in non-partition-tracked tables referenced in the materialized view's definition SQL, making it impossible to determine which partitions need updating, thus forcing a full refresh. For example: This materialized view tracks the o_orderdate partition of the orders table, but if data in lineitem or partsupp changes, the system cannot determine which partitions need updating, resulting in a full refresh.

```

CREATE MATERIALIZED VIEW partition_mv
BUILD IMMEDIATE
REFRESH AUTO
ON SCHEDULE EVERY 1 DAY STARTS '2024-12-01 20:30:00'
PARTITION BY (DATE_TRUNC(o_orderdate, 'MONTH'))
DISTRIBUTED BY HASH (l_orderkey) BUCKETS 2
PROPERTIES
('replication_num' = "3")
AS
SELECT
o_orderdate,
l_orderkey,
l_partkey
FROM
orders
LEFT JOIN lineitem ON l_orderkey = o_orderkey
LEFT JOIN partsupp ON ps_partkey = l_partkey
and l_suppkey = ps_suppkey;

```

You can check which base tables the materialized view tracks by running

```

SELECT *
FROM mv_infos('database'='db_name')
WHERE Name = 'partition_mv' \G

```

The returned result shows `partitionType=FOLLOW_BASE_TABLE` in `MvPartitionInfo`, indicating the materialized view partitions follow the base table partitions. `relatedCol` shows `o_orderdate`, meaning the materialized view partitions are based on the `o_orderdate` column.

```

Id: 1752809156450
Name: partition_mv
JobName: inner_mtmv_1752809156450
State: NORMAL
SchemaChangeDetail:
RefreshState: SUCCESS
RefreshInfo: BUILD IMMEDIATE REFRESH AUTO ON SCHEDULE EVERY 1 DAY STARTS "2024-12-01 20:30:00"
QuerySql: SELECT
`internal`.`doc_db`.`orders`.`o_orderdate`,
`internal`.`doc_db`.`lineitem`.`l_orderkey`,
`internal`.`doc_db`.`lineitem`.`l_partkey`
FROM
`internal`.`doc_db`.`orders`
LEFT JOIN `internal`.`doc_db`.`lineitem` ON `internal`.`doc_db`.`lineitem`.`l_orderkey` =
`internal`.`doc_db`.`orders`.`o_orderkey`
LEFT JOIN `internal`.`doc_db`.`partsupp` ON `internal`.`doc_db`.`partsupp`.`ps_partkey` =
`internal`.`doc_db`.`lineitem`.`l_partkey`
and `internal`.`doc_db`.`lineitem`.`l_suppkey` = `internal`.`doc_db`.`partsupp`.`ps_suppkey`
MvPartitionInfo: MTMVPPartitionInfo{partitionType=EXPR, relatedTable=orders, relatedCol='o_orderdate',
partitionCol='o_orderdate'}
SyncWithBaseTables: 1

```

Solution:

If changes in `lineitem` or `partsupp` tables don't affect your materialized view, you can exclude these tables from triggering full refreshes by setting the `excluded_trigger_tables` property: `ALTER MATERIALIZED VIEW partition_mv set("excluded_trigger_tables"="lineitem,partsupp");`

Queries and Transparent Rewriting

Q1: How to confirm if a Materialized View hits, and how to find the reasons for Non-Hits?

You can use `explain query_sql` to view a summary of materialized view hits.

For example, consider the following materialized view:

```
CREATE MATERIALIZED VIEW mv11
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
partition by(l_shipdate)
DISTRIBUTED BY HASH(l_orderkey) BUCKETS 10
PROPERTIES ('replication_num' = '1')
AS
SELECT l_shipdate, l_orderkey, O_ORDERDATE, count(*)
FROM lineitem
LEFT OUTER JOIN orders on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_orderkey, O_ORDERDATE;
```

The query can be:

```
explain
SELECT l_shipdate, l_orderkey, O_ORDERDATE, count(*)
FROM lineitem
LEFT OUTER JOIN orders on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_orderkey, O_ORDERDATE;
```

- The materialized view hit information is at the end of the plan.
- **MaterializedViewRewriteSuccessAndChose:** Indicates that transparent rewriting was successful, and lists the names of the materialized views chosen by the Cost-Based Optimizer (CBO).
- **MaterializedViewRewriteSuccessButNotChose:** Indicates that transparent rewriting was successful, but lists the names of materialized views that were not chosen by the CBO. Not choosing them means the execution plan will not use these materialized views.
- **MaterializedViewRewriteFail:** Lists the failures and summaries of the reasons for transparent rewriting failures.
- If there is no MaterializedView information at the end of the `explain` output, it means the materialized view is in an unusable state and therefore cannot participate in transparent rewriting. (For details on when a materialized view becomes unusable, refer to the “Usage and Practice - Viewing Materialized View Status” section.)

Here's an example output:

```
| MaterializedView |
| MaterializedViewRewriteSuccessAndChose: |
| internal#regression_test_nereids_rules_p0_mv#mv11, |
| |
| MaterializedViewRewriteSuccessButNotChose: |
| |
| MaterializedViewRewriteFail: |
+-----+
```

Q2: What Are the Reasons for a Materialized View Not Hitting?

First, to confirm if a materialized view hits, execute the following SQL (refer to [Queries and Transparent Rewriting - Q1](#) for details):

```
explain
your_query_sql;
```

If there is no hit, the following reasons may apply:

- In Doris versions before 2.1.3, the transparent rewriting feature for materialized views is disabled by default. You need to enable the corresponding switch to achieve transparent rewriting. For specific switch values, refer to [async-materialized view-related switches](#).
- The materialized view may be in an unusable state, preventing transparent rewriting from hitting it. To view the build status of the materialized view, refer to the section on [viewing materialized view status](#).
- If, after checking the first two steps, the materialized view still does not hit, it may be because SQL defines the materialized view and the query SQL is outside the current rewriting capabilities of the materialized view. Refer to the [Materialized View Transparent Rewriting Capabilities](#) for details.
- For detailed information and explanations on failed hits, refer to [Appendix 1](#).

Here's an example of a failed transparent rewriting for a materialized view:

Case 1:

Materialized view creation SQL:

```
CREATE MATERIALIZED VIEW mv11
BUILD IMMEDIATE REFRESH AUTO ON MANUAL
partition by(l_shipdate)
DISTRIBUTED BY HASH(l_orderkey) BUCKETS 10
PROPERTIES ('replication_num' = '1')
AS
SELECT l_shipdate, l_orderkey, O_ORDERDATE, count(*)
FROM lineitem
LEFT OUTER JOIN orders on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_orderkey, O_ORDERDATE;
```

Query execution:

```
explain
SELECT l_shipdate, l_linestatus, O_ORDERDATE, count(*)
FROM orders
LEFT OUTER JOIN lineitem on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_linestatus, O_ORDERDATE;
```

Explain output:

```
| MaterializedView |
| MaterializedViewRewriteSuccessAndChose: |
| |
| MaterializedViewRewriteSuccessButNotChose: |
```

```
|
| MaterializedViewRewriteFail:
|   Name: internal#doc_test#mv11
|   FailSummary: View struct info is invalid, The graph logic between query and view is not consistent
|
```

In the output, MaterializedViewRewriteFail shows a failure summary, where The graph logic between query and view is not consistent indicates that the join logic between the query and the materialized view is not the same, meaning the join type or tables joined differ.

In the above example, the table join order in the query and materialized view is inconsistent, hence the error. Refer to Appendix 1 for summaries and explanations of transparent rewriting failures.

Case 2:

Query execution:

```
explain
SELECT l_shipdate, l_linestatus, O_ORDERDATE, count(*)
FROM lineitem
LEFT OUTER JOIN orders on l_orderkey = o_orderkey
GROUP BY l_shipdate, l_linestatus, O_ORDERDATE;
```

Explain output:

```
| MaterializedView
|
| MaterializedViewRewriteSuccessAndChose:
|
|
|
| MaterializedViewRewriteSuccessButNotChose:
|
|
|
| MaterializedViewRewriteFail:
|
|   Name: internal#doc_test#mv11
|
|   FailSummary: View struct info is invalid, View dimensions doesn't not cover the query dimensions
|
```

The failure summary View dimensions doesn't cover the query dimensions indicates that the GROUP BY fields in the query cannot be obtained from the GROUP BY fields of the materialized view, hence the error.

Q3: What Situations Can Lead to a Materialized View's State Changing and Becoming Unusable?

By “unusable,” we mean that the materialized view cannot be used for transparent rewriting, though it can still be queried directly.

- For full materialized views, changes to the underlying table data or Schema Change can render the materialized view unusable.
- For partitioned materialized views, changes to the underlying table data can render the corresponding partitions unusable, while Schema Change of the underlying table can render the entire materialized

view unusable.

Currently, failed refreshes of materialized views can also make them unusable. However, optimizations are planned to allow even failed materialized views to be used for transparent rewriting.

Q4: What If Direct Queries to a Materialized View Return No Data?

It's possible that the materialized view is still being built or that the building has failed.

You can check the status of the materialized view to confirm this. Refer to the section on viewing materialized view status for specific methods.

Q5: When the Data in the Base Table Used by a Materialized View Changes, but the Materialized View Has Not Yet Been Refreshed, What Is the Behavior of Transparent Rewriting?

There is a certain delay between the data in async-materialized views and the underlying tables.

1. For internal tables and external tables that can perceive data changes (like Hive): When the underlying table data changes, whether the materialized view is usable depends on the `grace_period` threshold.

`grace_period` is the time period that allows for data inconsistency between the materialized view and the underlying table. For example:

- If `grace_period` is set to 0, it means the materialized view must be consistent with the underlying table data for it to be used for transparent rewriting. For external tables (except Hive), since they cannot perceive data changes, materialized views that use them can still be used for transparent rewriting (but the data may be inconsistent).
- If `grace_period` is set to 10 seconds, it allows for up to 10 seconds of delay between the materialized view data and the underlying table data. If the delay is within 10 seconds, the materialized view can still be used for transparent rewriting.

2. For partitioned materialized views, if some partitions become invalid, there are two scenarios:

- If the query does not use data from invalid partitions, the materialized view is still usable.
- If the query uses data from invalid partitions, and the data delay is within the `grace_period`, the materialized view is still usable. If the delay exceeds the `grace_period`, the query can be responded to by unioning the original table and the materialized view. This requires enabling the `enable_materialized_view_union_rewrite` switch, which is on by default from version 2.1.5.

Reference

1 Materialized View-Related Configuration

| Configuration | Description |
|---|---|
| SET <code>enable_nereids_planner</code> = true; | Enables the new optimizer required for materialized view rewriting. |

| Configuration | Description |
|---|--|
| SET enable_materialized_view_rewrite = true; | Enables or disables query rewriting. Default: Enabled. |
| SET materialized_view_rewrite_enable_contain_external_table = true; | Allows materialized views containing external tables to participate in rewriting. Default: Disabled. |
| SET materialized_view_rewrite_success_candidate_num = 3; | Maximum number of successful rewrite candidates considered by CBO. Default: 3. |
| SET enable_materialized_view_union_rewrite = true; | Allows UNION ALL between base tables and materialized views when data is insufficient. Default: Enabled. |
| SET enable_materialized_view_nest_rewrite = true; | Enables nested materialized view rewriting. Default: Disabled. |
| SET materialized_view_relation_mapping_max_count = 8; | Maximum number of relation mappings during rewriting. Default: 8. |

2 Summary and Description of Transparent Rewriting Failures

| Summary | Description |
|--|--|
| View struct info is invalid | The structure information of the materialized view is invalid. Currently supported SQL patterns for rewriting include joins in both queries and materialized views, and aggregations in queries with or without joins in materialized views. This error is often displayed during transparent rewriting, as each rewriting rule is responsible for a specific SQL pattern. If a rule is hit that does not match the required pattern, this error will occur, but it is generally not the primary cause of rewriting failure. |
| Materialized view rule exec fail | Typically indicates an exception during the execution of the transparent rewriting rule. To investigate, use EXPLAIN memo plan query_sql to view the specific exception stack. |
| Match mode is invalid | The number of tables in the query does not match the number of tables in the materialized view, and rewriting is not supported. |
| Query to view table mapping is null | Failed to generate the mapping between the query and materialized view tables. |
| queryToViewTableMappings are over the limit and be intercepted | Too many self-joined tables in the query led to excessive expansion of the rewriting space, stopping transparent rewriting. |
| Query to view slot mapping is null | Failed to map slots between the query and materialized view tables. |
| The graph logic between query and view is not consistent | The join types or joined tables between the query and materialized view are different. |
| Predicate compensate fail | Typically occurs when the query's condition range exceeds that of the materialized view, e.g., query is a > 10 but materialized view is a > 15. |
| Rewrite compensate predicate by view fail | Predicate compensation failed, usually because the query has additional conditions that need compensation, but the columns used in those conditions do not appear in the SELECT clause of the materialized view. |
| Calc invalid partitions fail | For partitioned materialized views, attempts to calculate whether partitions used by the query are valid failed. |

| Summary | Description |
|--|--|
| mv can not offer any partition for query | Query only uses invalid partitions of materialized view (data changed since last refresh). Check partition validity via show partitions from mv_name (SyncWithBaseTables=false indicates need for refresh). Set grace_period (in seconds) to allow data latency. |
| Add filter to base table fail when union rewrite | The query used invalid partitions of the materialized view, and attempting to union all the materialized view and base table failed. |
| RewrittenPlan output logical properties is different with target group | After rewriting, the output logical properties of the materialized view do not match those of the original query. |
| Rewrite expressions by view in join fail | In join rewriting, fields or expressions used in the query are not present in the materialized view. |
| Rewrite expressions by view in scan fail | In single-table rewriting, fields or expressions used in the query are not present in the materialized view. |
| Split view to top plan and agg fail, view doesn't not contain aggregate | During aggregation rewriting, the materialized view does not contain an aggregate function. |
| Split query to top plan and agg fail | During aggregation rewriting, the query does not contain an aggregate function. |
| rewritten expression contains aggregate functions when group equals aggregate rewrite | When the query and materialized view have the same GROUP BY, the rewritten expression contains aggregate functions. |
| Can not rewrite expression when no roll up | When the query and materialized view have the same GROUP BY, expression rewriting fails. |
| Query function roll up fail | During aggregation rewriting, the aggregation function roll-up fails. |
| View dimensions do not cover the query dimensions | The GROUP BY in the query uses dimensions not present in the GROUP BY of the materialized view. |
| View dimensions don't not cover the query dimensions in bottom agg | Similar to above, but specific to bottom-level aggregations. |
| View dimensions do not cover the query group set dimensions | The GROUP SETS in the query use dimensions not present in the GROUP BY of the materialized view. |
| The only one of query or view is scalar aggregate and can not rewrite expression meanwhile | The query has a GROUP BY but the materialized view does not. |
| Both query and view have group sets, or query doesn't have but view has, not supported | Unsupported transparent rewriting scenario involving GROUP SETS in both the query and materialized view, or only in the materialized view. |

3 Reasons of Async-Materialized View Partition Building Failures

The refresh mechanism for partitioned materialized views relies on incremental partition updates:

- First, calculate whether the partition columns of the materialized view can be mapped to those of the base table.
- Second, determine the specific mapping relationship, whether it is 1:1 or 1:n.

| Abstract | Description |
|--|---|
| Partition column cannot be found in the SQL SELECT column | The column used after PARTITION BY in the materialized view definition must appear in the SELECT clause of the SQL defining the materialized view. |
| Cannot find a valid partition track column, because %s | Unable to locate a suitable partition column; the specific reason follows "because". |
| Partition track does not support mark join | The column referenced by the partition field of the materialized view is a partition column of the input table in a mark join, which is currently not supported. |
| Partition column is in an unsupported join null generation side | The referenced column of the partition field in the materialized view is on the null-generating side of a join, such as the right side of a LEFT JOIN. |
| Relation should be LogicalCatalogRelation | The scan type of the partition base table referenced by the materialized view should be LogicalCatalogRelation; other types are currently not supported. |
| Self join does not support partition update | For SQL queries involving self-joins, constructing a materialized view is currently not supported. |
| Partition track already has a related base table column | The partition column referenced by the materialized view currently only supports referencing the partition column of a single base table. |
| Relation base table is not MTMVRelatedTableIf | The partition base table referenced by the materialized view does not inherit from MTMVRelatedTableIf, which indicates whether a table can be partitioned. |
| The related base table is not a partition table | The base table used by the materialized view is not a partition table. |
| The related base table partition column doesn't contain the MV partition | The column referenced after PARTITION BY in the materialized view does not exist in the partition base table. |
| Group BY sets are empty, does not contain the target partition | The SQL defining the materialized view uses aggregation, but the GROUP BY clause is empty. |
| Window partition sets do not contain the target partition | Window functions are used, but the partition column referenced by the materialized view is not in the PARTITION BY clause. |
| Unsupported plan operation in track partition | The SQL defining the materialized view uses unsupported operations, such as ORDER BY. |
| Context partition column should be a slot from column | Window functions are used, and in the PARTITION BY clause, the partition column referenced by the materialized view is not a simple column but an expression. |
| Partition expressions use more than one slot reference | The partition column after GROUP BY or PARTITION BY is an expression containing multiple columns, rather than a simple column. For example, GROUP BY partition_col + other_col. |
| Column to check using invalid implicit expression | The partition column of the materialized view can only be used in date_trunc, and the expression using the partition column can only be date_trunc, etc. |

| Abstract | Description |
|--|---|
| <p>Partition column time unit level should be greater than SQL SELECT column</p> | <p>In the materialized view, the time unit granularity in <code>date_trunc</code> after <code>PARTITION BY</code> is smaller than the time unit granularity appearing after <code>SELECT</code> in the SQL defining the materialized view. For example, the materialized view uses <code>PARTITION BY(date_trunc(col, 'day'))</code>, but the SQL defining the materialized view has <code>date_trunc(col, 'month')</code> after <code>SELECT</code>.</p> |

SQL Cache

Description

SQL Cache is a query optimization mechanism provided by Doris that can significantly enhance query performance. It reduces redundant computations by caching query results, making it suitable for scenarios where data update infrequently.

SQL Cache stores and retrieves caches based on the following key factors:

- SQL Text
- View Definitions
- Table and Partition Versions
- User Variables and Result Values
- Non-deterministic Functions and Result Values
- Row Policy Definitions
- Data Masking Definitions

The combination of these factors uniquely determines a cached dataset. If any of these factors change, such as variations in SQL, different query fields or conditions, or version changes after data updates, the cache will not be hit.

For queries involving multi-table joins, if one of the tables is updated, the partition ID or version number will differ, resulting in a cache miss.

SQL Cache is highly suitable for T+1 update scenarios. Data is updated early in the morning, the first query fetches results from the Backend (BE) and stores them in the cache, and subsequent queries of the same nature retrieve results directly from the cache. Real-time data updates can also use SQL Cache, but may face a lower cache hit rate.

Currently, SQL Cache supports both internal OlapTables and external Hive tables.

Usage Limitations

Non-Deterministic Functions

1. Non-deterministic functions refer to those whose computation results do not form a fixed relationship with their input parameters.
2. Take the common function `select now()` as an example. It returns the current date and time. Since this function returns different results when executed at different times, its return value is dynamically changing. The `now` function returns time at the second level, so SQL Cache from the previous second

can be reused within the same second; however, a new SQL Cache needs to be created for the next second.

3. To optimize cache utilization, it is recommended to convert such fine-grained time into coarse-grained time, such as using `select * from tbl where dt=date(now())`. In this case, queries within the same day can leverage the SQL Cache.
4. In contrast, the `random()` function is difficult to utilize cache because its results vary each time it is executed. Therefore, the use of such non-deterministic functions in queries should be avoided as much as possible.

Principles

BE Principle

In most cases, SQL Cache results are selected through a consistent hashing method to choose a BE and are stored in that BE's memory. These results are stored in a HashMap structure. When requests to read or write the cache arrive, the system uses a digest of metadata information, such as the SQL string, as a key to quickly retrieve and manipulate result data from the HashMap.

FE Principle

When the Frontend (FE) receives a query request, it first searches in its memory using the SQL string to determine if the same query has been executed before and attempts to retrieve the metadata information for that query. This information includes the versions of the tables and partitions involved in the query.

If these metadata remain unchanged, it indicates that the data in the corresponding tables has not been modified, allowing the reuse of the previous SQL Cache. In this case, the FE can skip the SQL parsing and optimization process, directly locate the corresponding BE based on the consistent hashing algorithm, and attempt to retrieve the query results from it.

- If the target BE contains a cached result for the query, the FE can quickly return the results to the client.
- Conversely, if the corresponding result cache is not found in the BE, the FE needs to execute the complete SQL parsing and optimization process and then transmit the query plan to the BE for computation and processing.

When the BE returns the computation results to the FE, the FE is responsible for storing these results in the corresponding BE and recording the metadata information of this query in its memory. This is done so that when the same query is received subsequently, the FE can directly retrieve the results from the BE, thereby improving query efficiency.

Additionally, if the SQL optimization phase determines that the query results contain only 0 or 1 row of data, the FE will choose to store these results in its memory to respond more quickly to potential future identical queries.

Get Started

Enabling and Disabling SQL Cache

```
-- Enable SQL Cache for the current session, default is disabled
set enable_sql_cache=true;
-- Disable SQL Cache for the current session
set enable_sql_cache=false;

-- Globally enable SQL Cache, default is disabled
set global enable_sql_cache=true;
-- Globally disable SQL Cache
set global enable_sql_cache=false;
```

Checking If a Query Hits SQL Cache

In Doris versions 2.1.3 and later, users can execute the `explain plan` statement to check if the current query successfully hits the SQL Cache.

As shown in the example, when the query plan tree contains `LogicalSqlCache` or `PhysicalSqlCache` nodes, it indicates that the query has hit the SQL Cache.

```
> explain plan select * from t2;

+-----+
+
| Explain String (Nereids Planner)
|
+-----+
+
| ===== PARSED PLAN (time: 28ms) =====
|
| LogicalSqlCache[1] ( queryId=711dea740e4746e6-8bc11afe08f6542c )
|
| +---PhysicalResultSink[39] ( outputExprs=[id#0, name#1] )
|
|   +---PhysicalOlapScan[t2]@0 ( stats=12 )
|
|
|
| ===== ANALYZED PLAN =====
|
| LogicalSqlCache[1] ( queryId=711dea740e4746e6-8bc11afe08f6542c )
|
| +---PhysicalResultSink[39] ( outputExprs=[id#0, name#1] )
|
|   +---PhysicalOlapScan[t2]@0 ( stats=12 )
|
|
|
| ===== REWRITTEN PLAN =====
|
| LogicalSqlCache[1] ( queryId=711dea740e4746e6-8bc11afe08f6542c )
|
| +---PhysicalResultSink[39] ( outputExprs=[id#0, name#1] )
|
|   +---PhysicalOlapScan[t2]@0 ( stats=12 )
|
|
```

```

|
| ===== OPTIMIZED PLAN =====
|
| PhysicalSqlCache[3] ( queryId=711dea740e4746e6-8bc11afe08f6542c, backend=192.168.126.3:9051, rowCount=12 )
|
| +---PhysicalResultSink[39] ( outputExprs=[id#0, name#1] )
|
|     +---PhysicalOlapScan[t2]@0 ( stats=12 )
|
|-----+
+

```

For versions before Doris 2.1.3, users need to check the Profile information to confirm if the query hits the SQL Cache. In the Profile information, if the `Is Cached:` field displays Yes, it indicates that the query has successfully hit the SQL Cache.

```

Execution Summary:
- Parse SQL Time: 18ms
- Nereids Analysis Time: N/A
- Nereids Rewrite Time: N/A
- Nereids Optimize Time: N/A
- Nereids Translate Time: N/A
- Workload Group: normal
- Analysis Time: N/A
- Wait and Fetch Result Time: N/A
- Fetch Result Time: 0ms
- Write Result Time: 0ms
- Doris Version: 915138e801
- Is Nereids: Yes
- Is Cached: Yes
- Total Instances Num: 0
- Instances Num Per BE:
- Parallel Fragment Exec Instance Num: 1
- Trace ID:
- Transaction Commit Time: N/A
- Nereids Distribute Time: N/A

```

Both methods provide effective means for users to verify whether queries utilize the SQL Cache, helping users better assess query performance and optimize query strategies.

Metrics and Monitor

1. The HTTP interface on the FE `http://${FE_IP}:${FE_HTTP_PORT}/metrics` **returns two relevant metrics:** This indicator counts the number of hits, which only increases and never decreases. When FE is restarted, the count starts from 0.

```

# Represents that 1 SQL has been written to the cache
doris_fe_cache_added{type="sql"} 1

# Represents that the SQL Cache has been hit twice
doris_fe_cache_hit{type="sql"} 2

```

2. The HTTP interface on the BE `http://${BE_IP}:${BE_HTTP_PORT}/metrics` **returns relevant information:** Since different caches may be stored in different BEs, it is necessary to collect metrics from all BEs to obtain complete information.

```
# Represents that there are 1205 caches in the memory of the current BE
doris_be_query_cache_sql_total_count 1205

# The current total memory occupied by all caches in the BE is 44k
doris_be_query_cache_memory_total_byte 44101
```

Memory Control

FE Memory Control

In FE, the metadata information of Cache is set to weak references. When FE memory is insufficient, the system will automatically release the least recently used Cache metadata. Additionally, users can further limit FE memory usage by executing the following SQL statements. This configuration takes effect in real-time and needs to be set for each FE. For persistent configuration, it should be saved in the `fe.conf` file.

```
-- Store up to 100 Cache metadata items, automatically releasing the least recently used ones when exceeded.
The default value is 100.
ADMIN SET FRONTEND CONFIG ('sql_cache_manage_num'='100');

-- Automatically release Cache metadata after 300 seconds of inactivity. The default value is 300.
ADMIN SET FRONTEND CONFIG ('expire_sql_cache_in_fe_second'='300');
```

BE Memory Control

Modify the following configurations in the `be.conf` file, and the changes will take effect after restarting BE:

```
-- When the Cache memory exceeds query_cache_max_size_mb + query_cache_elasticity_size_mb,
-- release the least recently used Cache until the memory usage is below query_cache_max_size_mb.
query_cache_max_size_mb = 256
query_cache_elasticity_size_mb = 128
```

Furthermore, configurations can be set in FE to avoid creating SQL Cache when the result row count or size exceeds certain thresholds:

```
-- By default, do not create SQL Cache for results exceeding 3000 rows.
ADMIN SET FRONTEND CONFIG ('cache_result_max_row_count'='3000');

-- By default, do not create SQL Cache for results exceeding 30MB.
ADMIN SET FRONTEND CONFIG ('cache_result_max_data_size'='31457280');
```

Troubleshooting Cache Miss

The reasons for cache invalidation typically include the following:

1. Changes in table/view structure, such as executing `drop table`, `replace table`, `alter table`, or `alter view`.
2. Changes in table data, such as executing `insert`, `delete`, `update`, or `truncate`.
3. Removal of user privileges, such as executing `revoke`.

4. Use of non-deterministic functions with changing evaluation values, such as executing `select random()`.
5. Use of variables with changing values, such as executing `select * from tbl where dt = @dt_var`.
6. Changes in Row Policy or Data Masking, such as setting certain table data to be invisible to users.
7. The result row count exceeds the FE-configured `cache_result_max_row_count`, with a default value of 3000 rows.
8. The result size exceeds the FE-configured `cache_result_max_data_size`, with a default value of 30MB.

High-Concurrency Point Query Optimization

Tips

This feature is supported since the Apache Doris 2.0 version

Description

Doris is built on a columnar storage format engine. In high-concurrency service scenarios, users always want to retrieve entire rows of data from the system. However, when tables are wide, the columnar format greatly amplifies random read IO. Doris query engine and planner are too heavy for some simple queries, such as point queries. A short path needs to be planned in the FE's query plan to handle such queries. FE is the access layer service for SQL queries, written in Java. Parsing and analyzing SQL also leads to high CPU overhead for high-concurrency queries. To solve these problems, we have introduced row storage, short query path, and PreparedStatement in Doris. Below is a guide to enable these optimizations.

Row Store Format

We support a row format for olap table to reduce point lookup io cost, but to enable this format, you need to spend more disk space for row format store. Currently, we store row in an extra column called `row` column for simplicity. The Row Storage mode can only be turned on when creating a table. You need to specify the following properties in the property of the table creation statement:

```
"store_row_column" = "true"
```

Accelerate point query for unique model

The above row storage is used to enable the Merge-On-Write strategy under the Unique model to reduce the IO overhead during enumeration. When `enable_unique_key_merge_on_write` and `store_row_column` are enabled when creating a Unique table, the query of the primary key will take a short path to optimize SQL execution, and only one RPC is required to complete the query. The following is an example of enabling the Merge-On-Write strategy under the Unique model by combining the query and row existence:

```
CREATE TABLE `tbl_point_query` (  
  `k1` int(11) NULL,  
  `v1` decimal(27, 9) NULL,  
  `v2` varchar(30) NULL,  
  `v3` varchar(30) NULL,  
  `v4` date NULL,  
  `v5` datetime NULL,  
  `v6` float NULL,  
  `v7` datev2 NULL  
) ENGINE=OLAP  
UNIQUE KEY(`k1`)  
COMMENT 'OLAP'  
DISTRIBUTED BY HASH(`k1`) BUCKETS 1
```

```

PROPERTIES (
  "replication_allocation" = "tag.location.default: 1",
  "enable_unique_key_merge_on_write" = "true",
  "light_schema_change" = "true",
  "store_row_column" = "true"
);

```

Note: 1. enable_unique_key_merge_on_write should be enabled, since we need primary key for quick point lookup in storage engine

2. when condition only contains primary key like `select * from tbl_point_query where key = 123`, such query will go through the short fast path
3. light_schema_change should also been enabled since we rely on column unique id of each column when doing a point query.
4. It only supports equality queries on the key column of a single table and does not support joins or nested subqueries. The WHERE condition should consist of the key column alone and be an equality comparison. It can be considered as a type of key-value query.
5. Enabling rowstore may lead to space expansion and occupy more disk space. For scenarios where querying only specific columns is needed, starting from Doris 3.0, it is recommended to use `"row_store_columns"="k1,v1,v2"` to specify certain columns for rowstore storage. Queries can then selectively access these columns, for example:

```

SELECT k1, v1, v2 FROM tbl_point_query WHERE k1 = 1

```

Using PreparedStatement

In order to reduce CPU cost for parsing query SQL and SQL expressions, we provide PreparedStatement feature in FE fully compatible with mysql protocol (currently only support point queries like above mentioned). Enable it will pre calculate PreparedStatement SQL and expressions and caches it in a session level memory buffer and will be reused later on. We could improve 4x+ performance by using PreparedStatement when CPU became bottleneck doing such queries. Bellow is an JDBC example of using PreparedStatement.

1. Setup JDBC url and enable server side prepared statement

```

url = jdbc:mysql://127.0.0.1:9030/ycsb?useServerPrepStmts=true

```

2. Using PreparedStatement

```

// use `?` for placement holders, readStatement should be reused
PreparedStatement readStatement = conn.prepareStatement("select * from tbl_point_query where k1 = ?");
...
readStatement.setInt(1,1234);
ResultSet resultSet = readStatement.executeQuery();
...
readStatement.setInt(1,1235);
resultSet = readStatement.executeQuery();
...

```

Enable row cache

Doris has a page-level cache that stores data for a specific column in each page. Therefore, the page cache is a column-based cache. For the row storage mentioned earlier, a row contains data for multiple columns, and the cache may be evicted by large queries, which can reduce the hit rate. To increase the hit rate of the row cache, a separate row cache is introduced, which reuses the LRU cache mechanism in Doris to ensure memory usage. You can enable it by specifying the following BE configuration:

- `disable_storage_row_cache` : Whether to enable the row cache. It is not enabled by default.
- `row_cache_mem_limit` : Specifies the percentage of memory occupied by the row cache. The default is 20% of memory.

Performance Optimization

1. Generally, it is effective to improve query processing capabilities by increasing the number of Observers.
2. Query load balancing: During the enumeration, if it is found that the FE CPU that accepts enumeration requests is used too high, or the request response becomes slow, you can use jdbc load balance for load balancing, and distribute the requests to multiple nodes to share the pressure (and also You can use other methods for query load balancing configuration, such as Nginx, proxySQL)
3. By directing the query requests to the Observer role to share the request pressure of high-concurrency queries and reducing the number of query requests sent to the fe master, it can usually solve the problem of the time-consuming fluctuation of the Fe Master node query to obtain better performance and stability

FAQ

1. How to confirm that the configuration is correct and short path optimization using concurrent enumeration is used ?

A: explain sql, when SHORT-CIRCUIT appears in the execution plan, it proves that short path optimization is used

```
mysql> explain select * from tbl_point_query where k1 = -2147481418 ;
```

```
+-----+
| Explain String(Old Planner)                                     |
+-----+
| PLAN FRAGMENT 0                                                |
|   OUTPUT EXPRS:                                                |
|   `test`.`tbl_point_query`.`k1`                                |
|   `test`.`tbl_point_query`.`v1`                                |
|   `test`.`tbl_point_query`.`v2`                                |
|   `test`.`tbl_point_query`.`v3`                                |

```

2. How to confirm that prepared statement is effective ?

A: After sending the request to Doris, find the corresponding query request in fe.audit.log and find Stmt=EXECUTE(), indicating that prepared statement is effective

```

2024-01-02 11:15:51,248 [query]
|Client=192.168.1.82:53450|User=root|Db=test|State=E0F|ErrorCode=0|ErrorMessage=|Time(ms)=49|ScanBytes=0|Scan
Rows=0|ReturnRows=1|StmtId=51|QueryId=b63d30b908f04dad-ab4a

3ba21d2c776b|IsQuery=true|isNereids=false|feIp=10.16.10.6|Stmt=EXECUTE(-2147481418)|CpuTimeMS=0|SqlHash=eee20
fa2ac13a4f93bd4503a87921024|peakMemoryBytes=0|SqlDigest=|TraceId=|WorkloadGroup=|FuzzyVaria
bles=

```

3. Can non-primary key queries use special optimization of high-concurrency point lookups?

A: No, high-concurrency query only targets the equivalent query of the key column, and the query cannot contain join or nested subqueries.

4. Is useServerPrepStmts useful in ordinary queries?

A: Prepared Statement currently only takes effect when primary key is checked.

5. Does optimizer selection require global settings?

A: When using prepared statement for query, Doris will choose the query method with the best performance, and there is no need to manually set the optimizer.

6. What should we do when the FE becomes a bottleneck?

A: If the FE is consuming too much CPU (i.e., high %CPU usage), enable the following configuration in the JDBC URL:

```

jdbc:mysql:loadbalance://[host1][:port],[host2][:port],[host3][:port]]/${tbl_name}?
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=500&prepStmtCacheSqlLimit=1024

```

- Enable loadbalance to ensure multiple FEs can serve requests, and the more FE instances, the better (deploy one per instance).
- Enable useServerPrepStmts to reduce parsing and planning overhead on the FE.

- Enable `cachePrepStmts` so the client caches prepared statements, reducing the need to frequently send prepare requests to the FE.
- Adjust `prepStmtCacheSize` to set the maximum number of cached query templates.
- Adjust `prepStmtCacheSqlLimit` to set the maximum length of a single cached SQL template.

7. How to optimize query performance under a compute-storage separation architecture?

A:

- set `global enable_snapshot_point_query = false`. Point queries require an additional RPC to the meta service to obtain the version, which can easily become a bottleneck under high QPS. Setting it to false can speed up queries but reduces data visibility (requires a trade-off between performance and consistency).
- Configure the BE parameter `enable_file_cache_keep_base_compaction_output=1` so that the result data after base compaction is stored in the cache, avoiding query jitter caused by remote access.

BITMAP Precise Deduplication

BITMAP Precise Deduplication

This document explains how to achieve precise deduplication using the Bitmap type.

Bitmap is an efficient bitmap indexing technique that uses bits to indicate the presence of corresponding data. It is particularly suitable for scenarios requiring efficient set operations (e.g., union, intersection) and is highly memory-efficient. Using Bitmap for precise deduplication offers the following benefits over COUNT DISTINCT:

- Improved query speed.
- Reduced memory/disk usage.

Implementation of Count Distinct

Traditional precise deduplication relies on COUNT DISTINCT. Consider the following example where deduplication is performed on the name column:

| id | name |
|----|------|
| 1 | bob |
| 2 | alex |
| 3 | jack |
| 4 | tom |
| 5 | bob |
| 6 | alex |

When Doris executes the query SELECT COUNT(DISTINCT name) FROM t, the process involves:

1. Grouping by the name column for stage-one deduplication.
2. Shuffling the grouped data.
3. Performing stage-two deduplication and finally counting the distinct names.

The process can be visualized as follows:

Since `COUNT DISTINCT` requires storing detailed data and performing shuffling, query performance slows down as the dataset grows. Using Bitmap for precise deduplication addresses the performance issues of `COUNT DISTINCT` in large datasets.

Use Cases

In large-scale data scenarios, the cost of deduplication using `COUNT DISTINCT` increases significantly, resulting in slower queries. Bitmap-based precise deduplication addresses these performance bottlenecks by mapping detailed data to bits. While sacrificing the flexibility of raw data, Bitmap greatly enhances computational efficiency. Consider using Bitmap in the following scenarios:

- **Query Acceleration:** Bitmap utilizes bitwise operations for computation, offering excellent performance.
- **Storage Compression:** Bitmap compresses detailed data into bits, significantly reducing resource consumption on disk and in memory.

However, Bitmap can only perform precise deduplication on data types such as `TINYINT`, `SMALLINT`, `INT`, and `BIGINT`. For other data types, a global dictionary must be constructed. Doris implements precise deduplication using `RoaringBitmap`. For more details, refer to [RoaringBitmap](#).

Use BITMAP for Precise Deduplication

Table Creation

1. When using Bitmap for deduplication, set the target column type to `BITMAP` in the table creation statement and specify `BITMAP_UNION` as the aggregate function.
2. Columns of type Bitmap cannot be used as key columns.

Create an aggregate table `test_bitmap`. The `id` column represents the user ID, and the `uv` column is of type `BITMAP`, using the aggregate function `BITMAP_UNION`:

```
CREATE TABLE test_bitmap(
  dt DATE,
  id INT,
  name CHAR(10),
  province CHAR(10),
  os CHAR(10),
  uv BITMAP BITMAP_UNION
)
```

```
AGGREGATE KEY (dt, id, name, province, os)
DISTRIBUTED BY HASH(id) BUCKETS 10;
```

Data Import

Here is a sample dataset (test_bitmap.csv) that can be imported using Stream Load:

```
2022-05-05,10001,Test 01,Beijing,windows
2022-05-05,10002,Test 01,Beijing,linux
2022-05-05,10003,Test 01,Beijing,macos
2022-05-05,10004,Test 01,Hebei,windows
2022-05-06,10001,Test 01,Shanghai,windows
2022-05-06,10002,Test 01,Shanghai,linux
2022-05-06,10003,Test 01,Jiangsu,macos
2022-05-06,10004,Test 01,Shaanxi,windows
```

Stream Load Command:

```
curl --location-trusted -u root: -H "label:label_test_bitmap_load" \
  -H "column_separator:," \
  -H "columns:dt,id,name,province,os, uv=to_bitmap(id)" -T test_bitmap.csv
http://fe_IP:8030/api/demo/test_bitmap/_stream_load
```

Querying Data

Bitmap columns cannot directly return raw values. Instead, use the BITMAP_UNION_COUNT aggregate function for queries.

Total UV Calculation:

```
SELECT BITMAP_UNION_COUNT(uv) FROM test_bitmap;
+-----+
| BITMAP_UNION_COUNT(`uv`) |
+-----+
| 4 |
+-----+
```

Equivalent to:

```
SELECT COUNT(DISTINCT id) FROM test_bitmap;
+-----+
| COUNT(DISTINCT `id`) |
+-----+
| 4 |
+-----+
```

Daily UV Calculation:

```
SELECT dt, BITMAP_UNION_COUNT(uv) FROM test_bitmap GROUP BY dt;
+-----+-----+
| dt | BITMAP_UNION_COUNT |
+-----+-----+
```

| | |
|------------|---------|
| 2022-05-05 | 4 |
| 2022-05-06 | 4 |
| +-----+ | +-----+ |

HLL Approximate Deduplication

HLL Approximate Deduplication

Use Cases

In real-world business scenarios, as the volume of business data grows, the pressure of deduplication also increases. When the data reaches a certain scale, the cost of precise deduplication becomes increasingly high. **HLL** (HyperLogLog) stands out for its excellent space complexity of $O(m \cdot \log \log n)$ time complexity of $O(n)$, and a controlled error rate of 1%–2%, depending on the dataset size and the hash function used.

When acceptable to the business, using approximate algorithms for fast deduplication is an effective way to reduce computational pressure.

What is HyperLogLog

HyperLogLog (HLL) is an enhanced version of the LogLog algorithm. It is used for approximate distinct counting and is mathematically based on **Bernoulli trials**.

Explanation:

Imagine flipping a coin with heads and tails. Each flip has a 50% probability of landing on either side. Keep flipping the coin until it shows heads, and record the number of flips as one trial.

For multiple Bernoulli trials:

- Let n be the number of heads obtained after n trials.
- Let k be the number of flips required in each trial. For example, if it took 12 flips to get heads in a trial, $k_{\max}$ would be 12 for this set of trials.

Bernoulli trials yield the following conclusions:

1. In n trials, no trial will require more than $k_{\max}$ flips.
2. At least one trial will require exactly $k_{\max}$ flips.

By applying maximum likelihood estimation, it can be derived that:

$$n = 2^{k_{\max}}$$

Thus, by recording only $k_{\max}$, the total number of unique items (cardinality) can be estimated.

Use HLL for Approximate Deduplication

Creating a Table

1. When using HLL for deduplication:

- The target column type must be set to HLL.
 - The aggregation function must be set to HLL_UNION.
2. HLL-type columns cannot be used as key columns.
 3. Users do not need to specify the length or default value. The system internally manages the length based on data aggregation levels.

Example table creation:

```
CREATE TABLE test_hll(  
    dt DATE,  
    id INT,  
    name CHAR(10),  
    province CHAR(10),  
    os CHAR(10),  
    uv HLL HLL_UNION  
)  
AGGREGATE KEY (dt, id, name, province, os)  
DISTRIBUTED BY HASH(id) BUCKETS 10  
PROPERTIES(  
    "replication_num" = "1",  
    "in_memory"="false"  
);
```

Importing Data

Here is sample data (test_hll.csv) that can be imported using Stream Load:

```
2022-05-05,10001,Test 01,Beijing,windows  
2022-05-05,10002,Test 01,Beijing,linux  
2022-05-05,10003,Test 01,Beijing,macos  
2022-05-05,10004,Test 01,Hebei,windows  
2022-05-06,10001,Test 01,Shanghai,windows  
2022-05-06,10002,Test 01,Shanghai,linux  
2022-05-06,10003,Test 01,Jiangsu,macos  
2022-05-06,10004,Test 01,Shaanxi,windows
```

Stream Load Command:

```
curl --location-trusted -u root: -H "label:label_test_hll_load" \  
    -H "column_separator:," \  
    -H "columns:dt,id,name,province,os, uv=hll_hash(id)" -T test_hll.csv  
http://fe_IP:8030/api/demo/test_hll/_stream_load
```

Result:

```
{  
    "TxnId": 693,  
    "Label": "label_test_hll_load",  
    "TwoPhaseCommit": "false",  
    "Status": "Success",  
    "Message": "OK",  
    "NumberTotalRows": 8,  
    "NumberLoadedRows": 8,  
    "NumberFilteredRows": 0,  
    "NumberUnselectedRows": 0,
```

```

    "LoadBytes": 320,
    "LoadTimeMs": 23,
    "BeginTxnTimeMs": 0,
    "StreamLoadPutTimeMs": 1,
    "ReadDataTimeMs": 0,
    "WriteDataTimeMs": 9,
    "CommitAndPublishTimeMs": 11
}

```

Querying Data

HLL columns cannot return raw values directly. Instead, HLL aggregate functions must be used for queries.

Total UV Calculation:

```

SELECT HLL_UNION_AGG(uv) FROM test_hll;
+-----+
| hll_union_agg(`uv`) |
+-----+
| 4 |
+-----+

```

Equivalent to:

```

SELECT COUNT(DISTINCT id) FROM test_hll;
+-----+
| count(DISTINCT `id`) |
+-----+
| 4 |
+-----+

```

Daily UV Calculation:

```

SELECT dt, HLL_UNION_AGG(uv) FROM test_hll GROUP BY dt;
+-----+-----+
| dt      | hll_union_agg |
+-----+-----+
| 2022-05-05 | 4 |
| 2022-05-06 | 4 |
+-----+-----+

```

Related Functions

- **HLL_UNION_AGG(hll)**: An aggregate function to estimate the cardinality of all data meeting the conditions.
- **HLL_CARDINALITY(hll)**: A function to calculate the cardinality of a single HLL column.
- **HLL_HASH(column_name)**: Generates an HLL column type, used during insert or data import (as shown above).
- **HLL_EMPTY()**: Generates an empty HLL column for default values during INSERT or data import.

Colocation Join

Colocation Join

Colocation Join provides local optimization for some Join queries to reduce data transmission time between nodes and accelerating query execution.

Note: This property will not be synchronized by CCR. If this table is copied by CCR, that is, `PROPERTIES` contains `is_being_synced = true`, this property will be erased in this table.

Noun Interpretation

- FE: Frontend, the front-end node of Doris. Responsible for metadata management and request access.
- BE: Backend, Doris's back-end node. Responsible for query execution and data storage.
- Colocation Group (CG): A CG contains one or more tables. Tables within the same group have the same Colocation Group Schema and the same data fragmentation distribution.
- Colocation Group Schema (CGS): Used to describe tables in a CG and general schema information related to Colocation. Including bucket column type, bucket number and copy number.

Principle

The Colocation Join function is to make a CG of a set of tables with the same CGS. Ensure that the corresponding data fragments of these tables will fall on the same BE node. When tables in CG perform Join operations on bucket columns, local data Join can be directly performed to reduce data transmission time between nodes.

The data of a table will eventually fall into a barrel according to the barrel column value Hash and the number of barrels modeled. Assuming that the number of buckets in a table is 8, there are eight buckets [0, 1, 2, 3, 4, 5, 6, 7] Buckets'. We call such a sequence a Buckets Sequence. Each Bucket has one or more Tablets. When a table is a single partitioned table, there is only one Tablet in a Bucket. If it is a multi-partition table, there will be more than one.

In order for a table to have the same data distribution, the table in the same CG must ensure the following attributes are the same:

1. Bucket column and number of buckets

Bucket column, that is, the column specified in `DISTRIBUTED BY HASH (col1, col2, ...)` in the table building statement. Bucket columns determine which column values are used to Hash data from a table into different Tablets. Tables in the same CG must ensure that the type and number of barrel columns are identical, and the number of barrels is identical, so that the data fragmentation of multiple tables can be controlled one by one.

2. Number of copies

The number of copies of all partitions of all tables in the same CG must be the same. If inconsistent, there may be a copy of a Tablet, and there is no corresponding copy of other table fragments on the same BE.

Tables in the same CG do not require consistency in the number, scope, and type of partition columns.

After fixing the number of bucket columns and buckets, the tables in the same CG will have the same Buckets Sequence. The number of replicas determines the number of replicas of Tablets in each bucket, which BE they are stored on. Suppose that Buckets Sequence is [0, 1, 2, 3, 4, 5, 6, 7], and that BE nodes have [A, B, C, D]4. A possible distribution of data is as follows:

```
+---+ +---+ +---+ +---+ +---+ +---+ +---+ +---+
| 0 | | 1 | | 2 | | 3 | | 4 | | 5 | | 6 | | 7 |
+---+ +---+ +---+ +---+ +---+ +---+ +---+ +---+
A		B		C		D		A		B		C		D
B		C		D		A		B		C		D		A
C		D		A		B		C		D		A		B
+---+ +---+ +---+ +---+ +---+ +---+ +---+ +---+
```

The data of all tables in CG will be uniformly distributed according to the above rules, which ensures that the data with the same barrel column value are on the same BE node, and local data Join can be carried out.

Usage

Establishment of tables

When creating a table, you can specify the attribute "colocate_with"="group_name" in PROPERTIES, which means that the table is a Colocation Join table and belongs to a specified Colocation Group.

Examples:

```
CREATE TABLE tbl (k1 int, v1 int sum)
DISTRIBUTED BY HASH(k1)
BUCKETS 8
PROPERTIES(
  "colocate_with" = "group1"
);
```

If the specified group does not exist, Doris automatically creates a group that contains only the current table. If the Group already exists, Doris checks whether the current table satisfies the Colocation Group Schema. If satisfied, the table is created and added to the Group. At the same time, tables create fragments and replicas based on existing data distribution rules in Groups. Group belongs to a database, and its name is unique in a database. Internal storage is the full name of Group dbId_groupName, but users only perceive groupName.

In version 2.0, Doris supports cross-Database Group. When creating a table, you need to use the keyword `__global__` as a prefix of the Group name. like:

```
CREATE TABLE tbl (k1 int, v1 int sum)
DISTRIBUTED BY HASH(k1)
BUCKETS 8
PROPERTIES(
  "colocate_with" = "__global__group1"
);
```

The Group prefixed with `__global__` no longer belongs to a Database, and its name is also globally unique.

Cross-Database Colocate Join can be realized by creating a Global Group.

Delete table

When the last table in Group is deleted completely (deleting completely means deleting from the recycle bin). Usually, when a table is deleted by the `DROP TABLE` command, it will be deleted after the default one-day stay in the recycle bin, and the group will be deleted automatically.

View Group

The following command allows you to view the existing Group information in the cluster.

```
SHOW PROC '/colocation_group';
```

| GroupId | GroupName | TableIds | BucketsNum | ReplicationNum | DistCols | IsStable |
|-------------|--------------|--------------|------------|----------------|----------|----------|
| 10005.10008 | 10005_group1 | 10007, 10040 | 10 | 3 | int(11) | true |

- **GroupId:** The unique identity of a group's entire cluster, with DB ID in the first half and group ID in the second half.
- **GroupName:** The full name of Group.
- **TableIds:** The group contains a list of Tables'ID.
- **Buckets Num:** Number of barrels.
- **Replication Num:** Number of copies.
- **DistCols:** Distribution columns,
- **IsStable:** Is the group stable (for the definition of stability, see section 'Collocation replica balancing and repair').

You can further view the data distribution of a group by following commands:

```
SHOW PROC '/colocation_group/10005.10008';
```

| BucketIndex | BackendIds |
|-------------|---------------------|
| 0 | 10004, 10002, 10001 |
| 1 | 10003, 10002, 10004 |
| 2 | 10002, 10004, 10001 |
| 3 | 10003, 10002, 10004 |
| 4 | 10002, 10004, 10003 |
| 5 | 10003, 10002, 10001 |
| 6 | 10003, 10004, 10001 |
| 7 | 10003, 10004, 10002 |

- **BucketIndex:** Subscript to the bucket sequence.
- **Backend Ids:** A list of BE node IDs where data fragments are located in buckets.

The above commands require ADMIN privileges. Normal user view is not supported at this time.

Modify Colocate Group

You can modify the Colocation Group property of a table that has been created. Examples:

```
ALTER TABLE tbl SET ("colocate_with" = "group2");
```

- If the table has not previously specified a Group, the command checks the Schema and adds the table to the Group (if the Group does not exist, it will be created).
- If other groups are specified before the table, the command first removes the table from the original group and adds a new group (if the group does not exist, it will be created).

You can also delete the Colocation attribute of a table by following commands:

```
ALTER TABLE tbl SET ("colocate_with" = "");
```

Other related operations

When an ADD PARTITION is added to a table with a Colocation attribute and the number of copies is modified, Doris checks whether the modification violates the Colocation Group Schema and rejects it if it does.

Colocation Duplicate Balancing and Repair

Copy distribution of Colocation tables needs to follow the distribution specified in Group, so it is different from common fragmentation in replica repair and balancing.

Group itself has a Stable attribute, when Stable is true, which indicates that all fragments of the table in the current Group are not changing, and the Colocation feature can be used normally. When Stable is false, it indicates that some tables in Group are being repaired or migrated. At this time, Colocation Join of related tables will degenerate into ordinary Join.

Replica Repair

Copies can only be stored on specified BE nodes. So when a BE is unavailable (downtime, Decommission, etc.), a new BE is needed to replace it. Doris will first look for the BE with the lowest load to replace it. After replacement, all data fragments on the old BE in the Bucket will be repaired. During the migration process, Group is marked Unstable.

Replica Balancing

Doris will try to distribute the fragments of the Collocation table evenly across all BE nodes. For the replica balancing of common tables, the granularity is single replica, that is to say, it is enough to find BE nodes with lower load for each replica alone. The equilibrium of the Colocation table is at the Bucket level, where all replicas within a Bucket migrate together. We adopt a simple equalization algorithm, which distributes Buckets Sequence evenly on all BEs, regardless of the actual size of the replicas, but only according to the number of replicas. Specific algorithms can be referred to the code annotations in ColocateTableBalancer.java.

Note 1: Current Colocation replica balancing and repair algorithms may not work well for heterogeneously deployed Doris clusters. The so-called heterogeneous deployment, that is, the BE node's disk capacity, number, disk type (SSD and HDD) is inconsistent. In the case of heterogeneous deployment, small BE nodes and large BE nodes may store the same number of replicas.

Note 2: When a group is in an Unstable state, the Join of the table in it will degenerate into a normal Join. At this time, the query performance of the cluster may be greatly reduced. If you do not want the system to balance automatically, you can set the FE configuration item `disable_colocate_balance` to prohibit automatic balancing. Then open it at the right time. (See Section Advanced Operations for details)

Query

The Colocation table is queried in the same way as ordinary tables, and users do not need to perceive Colocation attributes. If the Group in which the Colocation table is located is in an Unstable state, it will automatically degenerate to a normal Join.

Examples are given to illustrate:

Table 1:

```
CREATE TABLE `tbl1` (  
  `k1` date NOT NULL COMMENT "",  
  `k2` int(11) NOT NULL COMMENT "",  
  `v1` int(11) SUM NOT NULL COMMENT ""  
) ENGINE=OLAP  
AGGREGATE KEY(`k1`, `k2`)  
PARTITION BY RANGE(`k1`)  
(  
  PARTITION p1 VALUES LESS THAN ('2019-05-31'),  
  PARTITION p2 VALUES LESS THAN ('2019-06-30')  
)  
DISTRIBUTED BY HASH(`k2`) BUCKETS 8  
PROPERTIES (  
  "colocate_with" = "group1"  
);
```

Table 2:

```
CREATE TABLE `tbl2` (  
  `k1` datetime NOT NULL COMMENT "",  
  `k2` int(11) NOT NULL COMMENT "",  
  `v1` double SUM NOT NULL COMMENT ""  
) ENGINE=OLAP  
AGGREGATE KEY(`k1`, `k2`)  
DISTRIBUTED BY HASH(`k2`) BUCKETS 8  
PROPERTIES (  
  "colocate_with" = "group1"  
);
```

View the query plan:

```
DESC SELECT * FROM tbl1 INNER JOIN tbl2 ON (tbl1.k2 = tbl2.k2);
```

```
+-----+
| Explain String |
+-----+
| PLAN FRAGMENT 0 |
| OUTPUT EXPRS: `tbl1`.`k1` |
| PARTITION: RANDOM |
| |
| RESULT SINK |
| |
| 2:HASH JOIN |
	join op: INNER JOIN
	hash predicates:
	colocate: true
	`tbl1`.`k2` = `tbl2`.`k2`
	tuple ids: 0 1
	----1:OlapScanNode
	TABLE: tbl2
	PREAGGREGATION: OFF. Reason: null
	partitions=0/1
	rollup: null
	buckets=0/0
	cardinality=-1
	avgRowSize=0.0
	numNodes=0
	tuple ids: 1
0:OlapScanNode	
TABLE: tbl1	
PREAGGREGATION: OFF. Reason: No AggregateInfo	
partitions=0/2	
rollup: null	
buckets=0/0	
cardinality=-1	
avgRowSize=0.0	
numNodes=0	
tuple ids: 0	
+-----+
```

If Colocation Join works, the Hash Join Node will show colocate: true.

If not, the query plan is as follows:

```
+-----+
| Explain String |
+-----+
| PLAN FRAGMENT 0 |
| OUTPUT EXPRS: `tbl1`.`k1` |
| PARTITION: RANDOM |
| |
| RESULT SINK |
| |
| 2:HASH JOIN |
	join op: INNER JOIN (BROADCAST)
	hash predicates:
	colocate: false, reason: group is not stable
	`tbl1`.`k2` = `tbl2`.`k2`
	tuple ids: 0 1
	----3:EXCHANGE
+-----+
```

```

| | tuple ids: 1 |
| | |
| 0:0lapScanNode |
| TABLE: tbl1 |
| PREAGGREGATION: OFF. Reason: No AggregateInfo |
| partitions=0/2 |
| rollup: null |
| buckets=0/0 |
| cardinality=-1 |
| avgRowSize=0.0 |
| numNodes=0 |
| tuple ids: 0 |
|
| PLAN FRAGMENT 1 |
| OUTPUT EXPRS: |
| PARTITION: RANDOM |
|
| STREAM DATA SINK |
| EXCHANGE ID: 03 |
| UNPARTITIONED |
|
| 1:0lapScanNode |
| TABLE: tbl2 |
| PREAGGREGATION: OFF. Reason: null |
| partitions=0/1 |
| rollup: null |
| buckets=0/0 |
| cardinality=-1 |
| avgRowSize=0.0 |
| numNodes=0 |
| tuple ids: 1 |
+-----+

```

The HASH JOIN node displays the corresponding reason: `colocate: false, reason: group is not stable`. At the same time, an EXCHANGE node will be generated.

Advanced Operations

FE Configuration Item

- `disable_colocate_relocate`

Whether to close Doris's automatic Colocation replica repair. The default is false, i.e. not closed. This parameter only affects the replica repair of the Colocation table, but does not affect the normal table.

- `disable_colocate_balance`

Whether to turn off automatic Colocation replica balancing for Doris. The default is false, i.e. not closed. This parameter only affects the replica balance of the Collocation table, but does not affect the common table.

User can set these configurations at runtime. See `HELP ADMIN SHOW CONFIG;` and `HELP ADMIN SET CONFIG;`.

- `disable_colocate_join`

Whether to turn off the Colocation Join function or not. In 0.10 and previous versions, the default is true, that is, closed. In a later version, it will default to false, that is, open.

- `use_new_tablet_scheduler`

In 0.10 and previous versions, the new replica scheduling logic is incompatible with the Colocation Join function, so in 0.10 and previous versions, if `disable_colocate_join = false`, you need to set `use_new_tablet_scheduler = false`, that is, close the new replica scheduler. In later versions, `use_new_tablet_scheduler` will be equal to `true`.

HTTP RESTful API

Doris provides several HTTP RESTful APIs related to Colocation Join for viewing and modifying Colocation Group.

The API is implemented on the FE side and accessed using `fe_host: fe_http_port`. ADMIN privileges are required.

1. View all Colocation information for the cluster

```
GET /api/colocate

Return the internal Colocation info in JSON format:

{
  "msg": "success",
  "code": 0,
  "data": {
    "infos": [
      ["10003.12002", "10003_group1", "10037, 10043", "1", "1", "int(11)", "true"]
    ],
    "unstableGroupIds": [],
    "allGroupIds": [{
      "dbId": 10003,
      "grpId": 12002
    }]
  },
  "count": 0
}
```

2. Mark Group as Stable or Unstable

- Mark as Stable

```
```
DELETE /api/colocate/group_stable?db_id=10005&group_id=10008

Returns: 200
```
```

- Mark as Unstable

```
```
POST /api/colocate/group_stable?db_id=10005&group_id=10008

Returns: 200
```
```

3. Setting Data Distribution for Group

The interface can force the bucket sequence distribution of a group.

```
```\nPOST /api/colocate/bucketseq?db_id=10005&group_id=10008\n\nBody:\n[[10004,10002],[10003,10002],[10002,10004],[10003,10002],[10002,10004],[10003,10002],[10003,10004],\n[10003,10004],[10003,10004],[10002,10004]]\n\nReturns: 200\n```\n
```

Body is a Buckets Sequence represented by a nested array and the ID of the BE where the fragments are distributed in each Bucket.

Note that using this command, you may need to set the FE configuration `disable_colocate_relocate` and `disable_colocate_balance` to true. “This will prevent the system from automatically repairing or balancing Colocation replicas. Otherwise, it may be automatically reset by the system after modification.

# Overview of Hints

Database Hints are query optimization techniques used to guide the database query optimizer on how to generate a specific plan. By providing Hints, users can fine-tune the default behavior of the query optimizer in hopes of achieving better performance or meeting specific requirements.

## Note

Currently, Doris possesses excellent out-of-the-box capabilities. In most scenarios, Doris adaptively optimizes performance across various situations without requiring users to manually control hints for business tuning. The content presented in this chapter is primarily intended for professional tuning personnel. Business users can have a brief understanding of it.

## Hint Classification

Doris currently supports several types of hints, including leading hint, ordered hint, and distribute hint:

- [Leading Hint](#): Specifies the join order according to the order provided in the leading hint.
- [Ordered Hint](#): A specific type of leading hint that specifies the join order as the original text sequence.
- [Distribute Hint](#): Specifies the data distribution method for joins as either shuffle or broadcast.

## Hint Example

Imagine a table with a large amount of data. In certain specific cases, you may know that the join order of the tables can affect query performance. In such situations, the Leading Hint allows you to specify the table join order you want the optimizer to follow.

Take the following SQL query as an example. If the execution efficiency is not ideal, you may want to adjust the join order without changing the original SQL to avoid impacting the user's original scenario and achieve tuning goals.

```
mysql> explain shape plan select * from t1 join t2 on t1.c1 = c2;
+-----+
| Explain String |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN](t1.c1 = t2.c2) |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t1] |
+-----+
```

In this case, we can use the Leading Hint to arbitrarily change the join order of t1 and t2. For example:

```
mysql> explain shape plan select /*+ leading(t2 t1) */ * from t1 join t2 on t1.c1 = c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() build RFs:RF0 c1->[c2] |
| -----PhysicalOlapScan[t2] apply RFs: RF0 |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t1] |
| |
| Hint log: |
| Used: leading(t2 t1) |
| UnUsed: |
| SyntaxError: |
+-----+
```

In this example, the Leading Hint `/*+ leading(t2 t1) */` is used. The Leading Hint informs the optimizer to use the specified table (t2) as the driving table and place it before (t1) in the execution plan.

## Hint Log

The Hint Log is primarily used to display whether the hint is effective when executing EXPLAIN. It is usually located at the bottom of the EXPLAIN output.

Hint Log has three statuses:

```
+-----+
| Hint log: |
| Used: |
| UnUsed: |
| SyntaxError: |
+-----+
```

- **Used:** Indicates that the hint is effective.
- **UnUsed 和 SyntaxError:** Both indicate that the hint is not effective. SyntaxError indicates that there is a syntax error in using the hint or the syntax is not supported, and additional information about the unsupported reason will be provided.

Users can view the effectiveness and reasons for non-effectiveness through the Hint log, facilitating adjustments and verification.

## Summary

Hints are powerful tools for manually managing execution plans. Currently, Doris supports leading hint, ordered hint, distribute hint, etc., enabling users to manually manage join order, shuffle methods, and other variable configurations, providing users with more convenient and effective operational capabilities.

# Leading Hint

Leading Hint is a powerful query optimization technique that allows users to guide the Doris optimizer to determine the table join order in the query plan. Correct use of Leading Hint can significantly improve the performance of complex queries. This article will describe in detail how to use Leading Hint to control the join order in Doris.

## Regular Leading Hint

### Syntax

Leading Hint allows specifying the table join order that the optimizer should follow. In Doris, the basic syntax of Leading Hint is as follows:

```
SELECT /*+ LEADING(tablespec [tablespec]...) */ ...
```

It should be noted that:

- Leading Hint is surrounded by /\*+ and \*/ and placed after the SELECT keyword in the SQL statement.
- tablespec is the table name or table alias, and at least two tables need to be specified.
- Multiple tables are separated by spaces or ‘,’.
- You can use curly braces {} to explicitly specify the shape of the Join Tree.

For example:

```
mysql> explain shape plan select /*+ leading(t2 t1) */ * from t1 join t2 on c1 = c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t1] |
| |
| Hint log: |
| Used: leading(t2 t1) |
| UnUsed: |
| SyntaxError: |
+-----+
```

When Leading Hint is not effective, the normal process will be used to generate the plan. EXPLAIN will display whether the used Hint is effective, mainly divided into three types:

| Status | Description                         |
|--------|-------------------------------------|
| Used   | Leading Hint is effective normally. |

| Status      | Description                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unused      | The unsupported cases here include that the join order specified by Leading Hint is not equivalent to the original SQL or the feature is not supported in this version (see limitations for details). |
| SyntaxError | Indicates a syntax error in Leading Hint, such as the inability to find the corresponding table.                                                                                                      |

1. The default syntax of Leading Hint constructs a left-deep tree: `sql mysql> explain shape plan select /*+ leading(t1 t2 t3) */ * from t1 join t2 on c1 = c2 join t3 on c2=c3; +-----`  

```

-----+ |
Explain String(Nereids Planner) | +-----
-----+ | PhysicalResultSink | | --
PhysicalDistribute[DistributionSpecGather] | | ----PhysicalProject | | -----
hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() | | -----
hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() | | -----
PhysicalOlapScan[t1] | | -----PhysicalDistribute[DistributionSpecHash] | | -----
-----PhysicalOlapScan[t2] | | -----PhysicalDistribute[DistributionSpecHash] | |
-----PhysicalOlapScan[t3] | | | Hint log: | | Used: leading(t1 t2 t3) | |
Unused: | | SyntaxError: | +-----
-----+

```
2. At the same time, curly braces can be used to specify the shape of the Join tree: `sql mysql> explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 join t2 on c1 = c2 join t3 on c2=c3; +-----`  

```

-----+ | Explain String(Nereids Planner) | +-----
-----+ | PhysicalResultSink | | --
PhysicalDistribute[DistributionSpecGather] | | ----PhysicalProject | | -----
hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() | | -----
PhysicalOlapScan[t1] | | -----PhysicalDistribute[DistributionSpecHash] | | -----
---hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() | | -----
-----PhysicalOlapScan[t2] | | -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t3] | | | Hint log: | | Used: leading(t1 { t2 t3
}) | | Unused: | | SyntaxError: | +-----
-----+

```
3. When a View is used as an alias to participate in JoinReorder, the corresponding View can be specified as a parameter of Leading Hint. For example:

```

mysql> explain shape plan select /*+ leading(alias t1) */ count(*) from t1 join (select c2 from t2
join t3 on t2.c2 = t3.c3) as alias on t1.c1 = alias.c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg[GLOBAL] |
| ----PhysicalDistribute[DistributionSpecGather] |
| -----hashAgg[LOCAL] |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = alias.c2)) otherCondition=() |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----PhysicalProject |

```

```

| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t3]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t1]
|
| Hint log:
| Used: leading(alias t1)
| Unused:
| SyntaxError:
+-----+

```

## Case

### Basic Scenario

1. The table creation statements are as follows:

```

CREATE DATABASE testleading;
USE testleading;

create table t1 (c1 int, c11 int) distributed by hash(c1) buckets 3 properties('replication_num' = '1');
create table t2 (c2 int, c22 int) distributed by hash(c2) buckets 3 properties('replication_num' = '1');
create table t3 (c3 int, c33 int) distributed by hash(c3) buckets 3 properties('replication_num' = '1');
create table t4 (c4 int, c44 int) distributed by hash(c4) buckets 3 properties('replication_num' = '1');

```

2. The original plan:

```

mysql> explain shape plan select * from t1 join t2 on t1.c1 = c2;
+-----+
| Explain String
+-----+
| PhysicalResultSink
| --PhysicalDistribute
| ----PhysicalProject
| -----hashJoin[INNER_JOIN](t1.c1 = t2.c2)
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute
| -----PhysicalOlapScan[t1]
+-----+

```

3. When we need to exchange the join order of t1 and t2, we only need to add `leading(t2 t1)` in front. When executing `explain`, it will show whether this hint is used. The following is the Leading plan: Used indicates that the Hint is effective normally.

```

mysql> explain shape plan select /*+ leading(t2 t1) */ * from t1 join t2 on c1 = c2;
+-----+
| Explain String(Nereids Planner)
+-----+
| PhysicalResultSink
| --PhysicalDistribute[DistributionSpecGather]
+-----+

```

```

| ----PhysicalProject
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=()
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalOlapScan[t1]
|
| Hint log:
| Used: leading(t2 t1)
| Unused:
| SyntaxError:
+-----+

```

4. If there is a syntax error in Leading Hint, when executing explain, the corresponding information will be displayed in SyntaxError, but the plan can still be generated normally, just without using Leading. For example:

```

mysql> explain shape plan select /*+ leading(t2 t3) */ * from t1 join t2 on t1.c1 = c2;
+-----+
| Explain String
+-----+
| PhysicalResultSink
| --PhysicalDistribute
| ----PhysicalProject
| -----hashJoin[INNER_JOIN](t1.c1 = t2.c2)
| -----PhysicalOlapScan[t1]
| -----PhysicalDistribute
| -----PhysicalOlapScan[t2]
|
| Used:
| Unused:
| SyntaxError: leading(t2 t3) Msg:can not find table: t3
+-----+

```

## Extended Scenario

### 1. Left-Deep Tree

As mentioned above, when the query statement in Doris does not use any parentheses, Leading will default to generating a left-deep tree.

```

mysql> explain shape plan select /*+ leading(t1 t2 t3) */ * from t1 join t2 on t1.c1 = c2 join t3 on
c2 = c3;
+-----+
| Explain String(Nereids Planner)
+-----+
| PhysicalResultSink
| --PhysicalDistribute[DistributionSpecGather]
| ----PhysicalProject
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=()
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=()
| -----PhysicalOlapScan[t1]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalOlapScan[t3]
|
| Hint log:
| Used: leading(t1 t2 t3)
| Unused:
+-----+

```

|              |  |
|--------------|--|
| SyntaxError: |  |
| +-----+      |  |

## 2. Right-Deep Tree

When you need to make the shape of the plan a right-deep tree, Bushy tree, or zig-zag tree, you only need to add curly braces to limit the shape of the plan, without the need to use swap like Oracle to adjust step by step from the left-deep tree.

```
mysql> explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 join t2 on t1.c1 = c2 join t3 on
c2 = c3;
+-----+
| Explain String |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] (t1.c1 = t2.c2) |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute |
| -----hashJoin[INNER_JOIN] (t2.c2 = t3.c3) |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t3] |
| |
| Used: leading(t1 { t2 t3 }) |
| Unused: |
| SyntaxError: |
+-----+
```

## 3. Bushy Tree

```
mysql> explain shape plan select /*+ leading({t1 t2} {t3 t4}) */ * from t1 join t2 on t1.c1 = c2 join
t3 on c2 = c3 join t4 on c3 = c4;
+-----+
| Explain String |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] (t2.c2 = t3.c3) |
| -----hashJoin[INNER_JOIN] (t1.c1 = t2.c2) |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute |
| -----hashJoin[INNER_JOIN] (t3.c3 = t4.c4) |
| -----PhysicalOlapScan[t3] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t4] |
| |
| Used: leading({ t1 t2 } { t3 t4 }) |
| Unused: |
| SyntaxError: |
+-----+
```

## 4. zig-zag tree

```
mysql> explain shape plan select /*+ leading(t1 {t2 t3} t4) */ * from t1 join t2 on t1.c1 = c2 join t3
on c2 = c3 join t4 on c3 = c4;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t3.c3 = t4.c4)) otherCondition=() |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t3] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t4] |
| |
| Hint log: |
| Used: leading(t1 { t2 t3 } t4) |
| Unused: |
| SyntaxError: |
+-----+
```

## 5. Non-inner Join

When encountering a non-inner join (such as Outer Join or Semi/Anti Join), Leading Hint will automatically derive the join method of each join according to the original SQL semantics. If Leading Hint is different from the original SQL semantics or cannot be generated, it will be placed in Unused, but this does not affect the normal generation of the plan. The following is an example that cannot be swapped:

```
----- test outer join which can not swap
-- t1 leftjoin (t2 join t3 on (P23)) on (P12) != (t1 leftjoin t2 on (P12)) join t3 on (P23)
mysql> explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 left join t2 on c1 = c2 join t3
on c2 = c3;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t3] |
| |
| Hint log: |
| Used: |
| Unused: leading(t1 { t2 t3 }) |
| SyntaxError: |
+-----+
```

Here are some examples of Outer, Semi, and Anti Joins with Leading Hint for readers to verify on their own.

```

----- test outer join which can swap
-- (t1 leftjoin t2 on (P12)) innerjoin t3 on (P13) = (t1 innerjoin t3 on (P13)) leftjoin t2 on (P12)
explain shape plan select * from t1 left join t2 on c1 = c2 join t3 on c1 = c3;
explain shape plan select /*+ leading(t1 t3 t2) */ * from t1 left join t2 on c1 = c2 join t3 on c1 =
c3;

-- (t1 leftjoin t2 on (P12)) leftjoin t3 on (P13) = (t1 leftjoin t3 on (P13)) leftjoin t2 on (P12)
explain shape plan select * from t1 left join t2 on c1 = c2 left join t3 on c1 = c3;
explain shape plan select /*+ leading(t1 t3 t2) */ * from t1 left join t2 on c1 = c2 left join t3 on
c1 = c3;

-- (t1 leftjoin t2 on (P12)) leftjoin t3 on (P23) = t1 leftjoin (t2 leftjoin t3 on (P23)) on (P12)
select /*+ leading(t2 t3 t1) SWAP_INPUT(t1) */ * from t1 left join t2 on c1 = c2 left join t3 on c2 =
c3;
explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 left join t2 on c1 = c2 left join t3 on
c2 = c3;
explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 left join t2 on c1 = c2 left join t3 on
c2 = c3;

----- test outer join which can not swap
-- t1 leftjoin (t2 join t3 on (P23)) on (P12) != (t1 leftjoin t2 on (P12)) join t3 on (P23)
-- eliminated to inner join
explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 left join t2 on c1 = c2 join t3 on c2 =
c3;
explain graph select /*+ leading(t1 t2 t3) */ * from t1 left join (select * from t2 join t3 on c2 =
c3) on c1 = c2;

-- test semi join
explain shape plan select * from t1 where c1 in (select c2 from t2);
explain shape plan select /*+ leading(t2 t1) */ * from t1 where c1 in (select c2 from t2);

-- test anti join
explain shape plan select * from t1 where exists (select c2 from t2);

```

## 6. View

In the case of involving aliases (Alias), the alias can be specified as a complete and independent subtree, and the join order is generated according to the text order

```

mysql> explain shape plan select /*+ leading(alias t1) */ count(*) from t1 join (select c2 from t2
join t3 on t2.c2 = t3.c3) as alias on t1.c1 = alias.c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg[GLOBAL] |
| ----PhysicalDistribute[DistributionSpecGather] |
| -----hashAgg[LOCAL] |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = alias.c2)) otherCondition=() |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----PhysicalProject |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalProject |
| -----PhysicalOlapScan[t3] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalProject |
| -----PhysicalOlapScan[t1] |
| |
| Hint log: |

```

```

| Used: leading(alias t1)
| Unused:
| SyntaxError:
+-----+

```

## Ordered Hint

Ordered hint can be regarded as a special case of leading hint and is used to control the join order as the text order.

## Syntax

The syntax of Ordered Hint is `/*+ ORDERED */`, which is placed after the `SELECT` keyword in the `SELECT` statement, followed immediately by the rest of the query.

## Case

The following is an example of using Ordered Hint:

```

mysql> explain shape plan select /*+ ORDERED */ t1.c1 from t2 join t1 on t1.c1 = t2.c2 join t3 on c2 = c3;
+-----+
| Explain String(Nereids Planner)
+-----+
| PhysicalResultSink
| --PhysicalDistribute[DistributionSpecGather]
| ----PhysicalProject
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=()
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=()
| -----PhysicalProject
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t1]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t3]
|
| Hint log:
| Used: ORDERED
| Unused:
| SyntaxError:
+-----+

```

## Relationship with Leading Hint

When Ordered Hint and Leading Hint are used simultaneously, Ordered Hint will take precedence over Leading Hint. This means that even if Leading Hint is specified, if Ordered Hint also exists, the query plan will be executed according to the rules of Ordered Hint, and Leading Hint will be ignored. The following is an example showing the situation when both are used simultaneously:

```

mysql> explain shape plan select /*+ ORDERED LEADING(t1 t2 t3) */ t1.c1 from t2 join t1 on t1.c1 = t2.c2 join
t3 on c2 = c3;
+-----+
| Explain String(Nereids Planner)
+-----+

```

```

| PhysicalResultSink
| --PhysicalDistribute[DistributionSpecGather]
| ----PhysicalProject
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=()
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=()
| -----PhysicalProject
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t1]
| -----PhysicalDistribute[DistributionSpecHash]
| -----PhysicalProject
| -----PhysicalOlapScan[t3]
|
| Hint log:
| Used: ORDERED
| Unused: leading(t1 t2 t3)
| SyntaxError:
+-----+

```

## Summary

Leading Hint is a powerful feature for manually controlling the join order and is widely used in production business tuning. Using leading hint well can meet the tuning requirements for the join order on site and increase the flexibility of system control

# Distribute Hint

## Overview

The Distribute hint is used to control the shuffle method for joins.

## Syntax

- Supports specifying the Distribute Type for the right table, which can be either [shuffle] or [broadcast], and should be written before the right table in the Join.
- Supports an arbitrary number of Distribute Hints.
- When encountering a Distribute Hint that cannot correctly generate a plan, the system will not display an error. It will make the best effort to apply the hint, and the final Distribute method will be shown in the EXPLAIN output.

## Examples

### Used in Combination with Ordered Hint

Fix the Join order to the textual sequence, and then specify the expected Distribute method for the Join. For example:

Before using:

```
mysql> explain shape plan select count(*) from t1 join t2 on t1.c1 = t2.c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg[GLOBAL] |
| ----PhysicalDistribute[DistributionSpecGather] |
| -----hashAgg[LOCAL] |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalProject |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalProject |
| -----PhysicalOlapScan[t2] |
+-----+
```

After using:

```
mysql> explain shape plan select /*+ ordered */ count(*) from t2 join[broadcast] t1 on t1.c1 = t2.c2;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg[GLOBAL] |
| ----PhysicalDistribute[DistributionSpecGather] |
| -----hashAgg[LOCAL] |
+-----+
```

```

| -----PhysicalProject
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=()
| -----PhysicalProject
| -----PhysicalOlapScan[t2]
| -----PhysicalDistribute[DistributionSpecReplicated]
| -----PhysicalProject
| -----PhysicalOlapScan[t1]
|
| Hint log:
| Used: ORDERED
| UnUsed:
| SyntaxError:
+-----+

```

The Explain Shape Plan will display information related to the Distribute operator. Specifically:

- DistributionSpecReplicated indicates that the corresponding data will be replicated to all BE nodes.
- DistributionSpecGather indicates that the data will be gathered to the FE node.
- DistributionSpecHash indicates that the data will be distributed to different BE nodes based on a specific hashKey and algorithm. **Used in Combination with Leading Hint**

When writing SQL queries, you can specify the corresponding DISTRIBUTE method for each JOIN operation while using the LEADING hint. Below is a specific example demonstrating how to mix Distribute Hint and Leading Hint in an SQL query.

```

explain shape plan
select
 nation,
 o_year,
 sum(amount) as sum_profit
from
 (
 select
 /* leading(orders shuffle {lineitem shuffle part} shuffle {supplier broadcast nation}
shuffle partsupp) */
 n_name as nation,
 extract(year from o_orderdate) as o_year,
 l_extendedprice * (1 - l_discount) - ps_supplycost * l_quantity as amount
 from
 part,
 supplier,
 lineitem,
 partsupp,
 orders,
 nation
 where
 s_suppkey = l_suppkey
 and ps_suppkey = l_suppkey
 and ps_partkey = l_partkey
 and p_partkey = l_partkey
 and o_orderkey = l_orderkey
 and s_nationkey = n_nationkey
 and p_name like '%green%'
) as profit
group by
 nation,
 o_year
order by
 nation,
 o_year desc;

```

## Summary

The Distribute hint is a commonly used hint for controlling the join shuffle method, allowing manual specification of shuffle or broadcast distribution methods. Proper use of the Distribute hint can meet on-site tuning needs for join shuffle methods, increasing the flexibility of system control.

# Optimizing Table Schema Design

---

## Overview

In Schema design and tuning, table Schema design is a crucial part, encompassing table engine selection, partition and bucket column selection, partition and bucket size settings, key column and field type optimization, etc. Systems lacking proper Schema design may encounter issues such as data skew, failing to fully leverage system parallelism and sorting features, thereby hindering the Doris system from realizing its true performance advantages within business systems.

Detailed design principles can be found in the [Data Table Design](#) section for further information. This chapter, from the perspective of practical cases, will showcase performance bottlenecks caused by Schema design issues in several typical scenarios and provide optimization suggestions for business tuning reference.

## Case 1: Table Engine Selection

Doris supports three table models: Duplicate, Unique, and Aggregate. Among them, Unique can be further divided into Merge-On-Read (MOR) and Merge-On-Write (MOW).

The query performance of these table models, from best to worst, is: Duplicate > MOW > MOR == Aggregate. Therefore, under normal circumstances, if there are no special requirements, the Duplicate table is recommended for better query performance.

**When the business has no data update requirements but high demands for query performance, the [Duplicate table](#) is recommended.**

## Case 2: Bucket Column Selection

Doris supports bucketing data, which means distributing data based on bucket keys in the Schema to form data buckets.

Selecting appropriate bucket columns is vital for the reasonable distribution of raw data, effectively preventing performance issues caused by data skew. Meanwhile, it maximizes the utilization of Doris's Colocate Join and Bucket Shuffle Join features, significantly enhancing the performance of Join operations.

Taking the table creation statement of table t1 as an example, the current bucket column is set as c2. However, during the actual data import process, if all values of column c2 are defaulted to null, even if 64 buckets are set, only one bucket will contain all the data. This extreme case leads to severe data skew, resulting in performance bottlenecks.

```
CREATE TABLE `t1` (
 `c1` INT NULL,
 `c2` INT NULL
) ENGINE=OLAP
DUPLICATE KEY(`c1`)
DISTRIBUTED BY HASH(`c2`) BUCKETS 64
```

```

PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
insert into t1 select number, null from numbers ('number'='10000000');

```

In response to the above situation, we can change the bucket column from c2 to c1 to achieve adequate data hashing and maximize the system's parallel processing capabilities, thereby achieving tuning purposes.

Therefore, during the Schema design phase, business personnel need to design reasonable bucket columns beforehand based on business characteristics. For instance, if it is known beforehand that the business meaning of column c2 may contain a large number of skewed values, such as null or certain specific values, these fields should be avoided as bucket columns. Conversely, fields with adequate hashing characteristics in business meaning, such as user ID, should be selected as bucket columns. During the performance issue troubleshooting phase, the following SQL statement can be used to confirm whether the bucket field has data skew and make subsequent optimization adjustments accordingly.

```

select c2, count(*) cnt from t1 group by c2 order by cnt desc limit 10;

```

**Check whether the bucket column has data skew issues. If so, replace it with a field that has adequate hashing characteristics in business meaning as the bucket column.**

It is clear that good prior design can significantly reduce the cost of locating and correcting issues when they occur. Therefore, it is strongly recommended that business personnel conduct rigorous design and checks during the Schema design phase to avoid introducing unnecessary costs.

### Case 3: Key Column Optimization

Among the three table models, if the table creation Schema explicitly specifies a Duplicate Key, Unique Key, or Aggregate Key, Doris will ensure that data is sorted based on the Key column at the storage level. This feature provides new ideas for data query performance optimization. Specifically, during the Schema design phase, if columns frequently used for equality or range queries in business queries can be defined as Key columns, it will significantly increase the execution speed of such queries, thereby enhancing overall performance.

Here is a set of examples of business query requirements:

```

select * from t1 where t1.c1 = 1;
select * from t1 where t1.c1 > 1 and t1.c1 < 10;
select * from t1 where t1.c1 in (1, 2, 3);

```

For the above business requirements and the Schema design and later optimization of table t1, considering setting column c1 as the Key column to accelerate the query process is advisable. Here is an example:

```

CREATE TABLE `t1` (
 `c1` INT NULL,
 `c2` INT NULL
) ENGINE=OLAP
DUPLICATE KEY(`c1`)
DISTRIBUTED BY HASH(`c2`) BUCKETS 10
PROPERTIES (

```

```
"replication_allocation" = "tag.location.default: 1"
);
```

**Set columns frequently used in business queries as key columns to accelerate the query process.**

## Case 4: Field Type Optimization

In database systems, the complexity of processing different types of data can vary significantly. For example, processing variable-length types is much more complex than fixed-length types; similarly, processing high-precision types is more complex than low-precision types.

This characteristic provides important insights into the design and later optimization of business system Schemas:

1. While meeting the expression and computation needs of business systems, priority should be given to fixed-length types, avoiding the use of variable-length types;
2. At the same time, low-precision types should be adopted instead of high-precision types. Specific practices include using BIGINT to replace VARCHAR or STRING type fields and using FLOAT / INT / BIGINT to replace DECIMAL type fields. Reasonable design and optimization of such field types will greatly enhance business computation efficiency, thereby improving system performance.

**When defining Schema types, follow the principle of prioritizing fixed-length and low-precision types.**

## Summary

In summary, a well-designed Schema can maximize the utilization of Doris's features, thereby significantly enhancing business performance. Conversely, a non-optimized Schema design may have a global negative impact on the business, such as causing data skew. Therefore, the initial Schema design optimization work is particularly important.

# Optimizing Table Index Design

---

## Overview

Doris currently supports two types of indexes:

1. Built-in Indexes: These include prefix indexes, ZoneMap indexes, etc.
2. Secondary Indexes: These include inverted indexes, Bloom filter indexes, N-Gram Bloom filter indexes, and Bitmap indexes, etc.

In the process of business optimization, fully analyzing business characteristics and make effective use of indexes can greatly enhance the effectiveness of queries and analyses, thereby achieving the purpose of performance tuning.

For a detailed introduction to various indexes, please refer to the [Table Index](#) section. This chapter will demonstrate index usage techniques in several typical scenarios from the perspective of actual cases and summarize optimization suggestions for reference in business tuning.

## Case 1: Optimizing the Order of Key Columns to Leverage Prefix Indexes for Accelerated Queries

In [optimizing table schema design](#), we have introduced how to select appropriate fields as key fields and utilize Doris's key column sorting feature to accelerate queries. This case will further expand on this scenario.

Due to Doris's built-in prefix index function, it automatically takes the first 36 bytes of the table's Key as a prefix index when creating the table. When query conditions match the prefix of the prefix index, it can significantly speed up the query. Below is an example of a table definition:

```
CREATE TABLE `t1` (
 `c1` VARCHAR(10) NULL,
 `c2` VARCHAR(10) NULL
) ENGINE=OLAP
DUPLICATE KEY(`c1`)
DISTRIBUTED BY HASH(`c2`) BUCKETS 10
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

The corresponding business SQL pattern is as follows:

```
select * from t1 where t1.c2 = '1';
select * from t1 where t1.c2 in ('1', '2', '3');
```

In the above schema definition, c1 comes before c2. However, the queries use the c2 field for filtering. In this case, the acceleration function of the prefix index cannot be utilized. To optimize, we can adjust the definition order of c1 and c2, placing the c2 column in the first field position to leverage the acceleration function of the prefix index.

The adjusted schema is as follows:

```
CREATE TABLE `t1` (
 `c2` VARCHAR(10) NULL,
 `c1` VARCHAR(10) NULL
) ENGINE=OLAP
DUPLICATE KEY(`c2`)
DISTRIBUTED BY HASH(`c1`) BUCKETS 10
PROPERTIES (
 "replication_allocation" = "tag.location.default: 1"
);
```

**When defining the schema column order, reference the high-frequency and high-priority columns in business query filtering to fully leverage Doris's prefix index acceleration function.**

## Case 2: Using Inverted Indexes to Accelerate Queries

Doris supports inverted indexes as secondary indexes to accelerate business scenarios such as equal value, range, and full-text search of text types. The creation and management of inverted indexes are independent, allowing for convenient business performance optimization without affecting the original table schema and without the need to re-import table data.

For typical usage scenarios, syntax, and cases, please refer to the [Table Index - Inverted Index](#) section for a detailed introduction, so this chapter will not repeat the explanation.

**For full-text searches of text types and equal value or range queries on string, numeric, and datetime type fields, inverted indexes can be utilized to accelerate queries. Especially in certain situations, such as when the original table structure and key definition are not convenient to optimize, or the cost of re-importing table data is high, inverted indexes provide a flexible acceleration solution to optimize business execution performance.**

## Summary

In schema tuning, apart from table-level schema optimization, index optimization also occupies an important position. Doris provides multiple index types, including built-in indexes such as prefix index, as well as secondary indexes such as inverted indexes, which provide strong support for performance acceleration. By reasonably utilizing these indexes, we can significantly improve the speed of business queries and analyses in multiple scenarios, which is of great significance for multi-scenario business queries and analyses.

# Optimizing Table Scanning

---

## Overview

Doris, as a high-performance real-time analytic data warehouse, offers a powerful partition pruning feature that can significantly enhance query performance.

Partition pruning is a query optimization technique that intelligently identifies partitions relevant to a query by analyzing its conditions, and scans only the data within these partitions, thereby avoiding unnecessary scans of irrelevant partitions. This approach can greatly reduce I/O operations and computational load, thus accelerating query execution.

## Case

Here is a usage case to demonstrate Doris's partition pruning feature.

Suppose we have a sales data table named `sales`, which is partitioned by date, with each day's data stored in a separate partition. The table structure is defined as follows:

```
CREATE TABLE sales (
 date DATE,
 product VARCHAR(50),
 amount DECIMAL(10, 2)
)
PARTITION BY RANGE(date) (
 PARTITION p1 VALUES LESS THAN ('2023-01-01'),
 PARTITION p2 VALUES LESS THAN ('2023-02-01'),
 PARTITION p3 VALUES LESS THAN ('2023-03-01'),
 PARTITION p4 VALUES LESS THAN ('2023-04-01')
)
DISTRIBUTED BY HASH(date) BUCKETS 16
PROPERTIES
(
 "replication_num" = "1"
);
```

Now, we need to query the total sales amount between January 15, 2023 and February 15, 2023. The query statement is as follows:

```
SELECT SUM(amount) AS total_amount
FROM sales
WHERE date BETWEEN '2023-01-15' AND '2023-02-15';
```

For the above query, Doris's partition pruning optimization process is as follows:

1. Doris intelligently analyzes the partition column `date` in the query conditions and identifies the date range of the query as being between '2023-01-15' and '2023-02-15'.
2. By comparing the query conditions with the partition definitions, Doris precisely locates the range of partitions that need to be scanned. In this example, only partitions `p2` and `p3` need to be scanned, as their date ranges fully cover the query conditions.

3. Doris automatically skips partitions unrelated to the query conditions, such as p1 and p4, avoiding unnecessary data scans and thereby reducing I/O overhead.
4. Finally, Doris performs data scanning and aggregation computations only within partitions p2 and p3, quickly obtaining the query results.

By using the EXPLAIN command, we can view the query execution plan and confirm that Doris's partition pruning optimization has taken effect. In the execution plan, the `partition` attribute of the `OlapScanNode` node will display the actually scanned partitions as p2 and p3.

```
| 0:V0lapScanNode(212) |
| TABLE: cir.sales(sales), PREAGGREGATION: ON |
| PREDICATES: (date[#0] >= '2023-01-15') AND (date[#0] <= '2023-02-15') |
| partitions=2/4 (p2,p3) |
```

## Summary

In summary, Doris's partition pruning feature can intelligently identify the relevance between query conditions and partitions, automatically prune irrelevant partitions, and scan only necessary data, thereby significantly enhancing query performance. Reasonable utilization of the partition pruning feature can help users build efficient real-time analytics systems and easily handle massive data query demands.

# Transparent Rewriting with Sync-Materialized View

---

## Overview

The [Sync-Materialized View](#) is a special kind of table that pre-computes and stores data according to a predefined SELECT statement. Its main purpose is to meet users' needs for analyzing raw detailed data from any dimension and also enable quick analysis and queries on fixed dimensions.

The applicable scenarios for synchronous materialized views are as follows:

1. The analysis requirements cover both detailed data queries and fixed-dimension queries.
2. The queries involve *only* a small number of columns or rows in the table.
3. The queries include time-consuming processing operations, such as long-duration aggregation operations.
4. The queries need to match different prefix indexes.

For queries that frequently and repeatedly use the results of the same subqueries, synchronous materialized views can significantly improve performance. Doris will automatically maintain the data of materialized views to ensure data consistency between the base table and the materialized view table, without requiring additional manual maintenance costs. During a query, the system will automatically match the optimal materialized view and directly read data from it.

### Precautions

- In Doris 2.0 and *later* versions, materialized views have some enhanced functions. It is recommended that users confirm in the test environment whether the expected queries can hit the materialized views they want to create before using materialized views in the formal production environment.
- It is not recommended to create multiple materialized views with similar forms on the same table, as this may lead to conflicts among multiple materialized views and thus cause query hit failures. :::

### Case

The following uses a specific example to demonstrate the process of using synchronous materialized views to accelerate queries:

Suppose we have a detailed sales record table named `sales_records`, which records various pieces of information for each transaction in detail, including the transaction ID, salesperson ID, selling store ID, sales date, and transaction amount. Now, we often need to conduct analysis and queries on the sales volume of different stores.

To optimize the performance of these queries, we can create a materialized view named `store_amt`. This view groups by the selling store and sums up the sales amounts of the same store. The specific steps are as follows:

## Create a Sync-Materialized View

Firstly, we use the following SQL statement to create the materialized view `store_amt`:

```
CREATE MATERIALIZED VIEW store_amt AS
SELECT store_id, SUM(sale_amt)
FROM sales_records
GROUP BY store_id;
```

After submitting the creation task, Doris will build this synchronous materialized view asynchronously in the background. We can use the following command to check the creation progress of the materialized view:

```
SHOW ALTER TABLE MATERIALIZED VIEW FROM db_name;
```

When the State field becomes `FINISHED`, it means that the `store_amt` materialized view has been successfully created.

## Transparent Rewriting

After the materialized view is created, when we query the sales volume of different stores, Doris will automatically match the `store_amt` materialized view and directly read the pre-aggregated data from it, thus significantly improving the query efficiency. The query statement is as follows:

```
SELECT store_id, SUM(sale_amt) FROM sales_records GROUP BY store_id;
```

We can also use the `EXPLAIN` command to check whether the query has successfully hit the materialized view:

```
EXPLAIN SELECT store_id, SUM(sale_amt) FROM sales_records GROUP BY store_id;
```

At the end of the execution plan, if something like the following is displayed, it means that the query has successfully hit the `store_amt` materialized view:

```
TABLE: default_cluster:test.sales_records(store_amt), PREAGGREGATION: ON
```

Through the above steps, we can use synchronous materialized views to optimize query performance and improve the efficiency of data analysis.

## Summary

By creating synchronous materialized views, we can significantly improve the query speed for relevant aggregation analysis. Single-table materialized views not only enable us to conduct statistical analysis quickly but also flexibly support the query needs for detailed data, which is a very powerful feature in Doris.

# Transparent Rewriting by Async-Materialized View

---

## Overview

The [Async-materialized view](#) adopts a transparent rewriting algorithm based on the SPJG (SELECT-PROJECT-JOIN-GROUP-BY) pattern. This algorithm can analyze the structural information of the query SQL, automatically find the appropriate materialized views, and attempt to perform transparent rewriting to express the query SQL using the optimal materialized views. By using the pre-computed results of materialized views, the query performance can be significantly improved and the computing cost can be reduced.

## Case

Next, an example will be used to demonstrate in detail how to utilize async-materialized views to accelerate queries.

## Create Base Tables

Firstly, create the tpch database and then create two tables, namely orders and lineitem, within it, and insert corresponding data.

```
CREATE DATABASE IF NOT EXISTS tpch;
USE tpch;

CREATE TABLE IF NOT EXISTS orders (
 o_orderkey integer not null,
 o_custkey integer not null,
 o_orderstatus char(1) not null,
 o_totalprice decimalv3(15,2) not null,
 o_orderdate date not null,
 o_orderpriority char(15) not null,
 o_clerk char(15) not null,
 o_shippriority integer not null,
 o_comment varchar(79) not null
)
DUPLICATE KEY(o_orderkey, o_custkey)
PARTITION BY RANGE(o_orderdate)(
 FROM ('2023-10-17') TO ('2023-10-20') INTERVAL 1 DAY
)
DISTRIBUTED BY HASH(o_orderkey) BUCKETS 3
PROPERTIES ("replication_num" = "1");

INSERT INTO orders VALUES
 (1, 1, 'o', 99.5, '2023-10-17', 'a', 'b', 1, 'yy'),
 (2, 2, 'o', 109.2, '2023-10-18', 'c', 'd', 2, 'mm'),
 (3, 3, 'o', 99.5, '2023-10-19', 'a', 'b', 1, 'yy');

CREATE TABLE IF NOT EXISTS lineitem (
 l_orderkey integer not null,
 l_partkey integer not null,
 l_suppkey integer not null,
 l_linenum integer not null,
```

```

 l_quantity decimalv3(15,2) not null,
 l_extendedprice decimalv3(15,2) not null,

 l_shipmode char(10) not null,
 l_comment varchar(44) not null
)
DUPLICATE KEY(l_orderkey, l_partkey, l_suppkey, l_linenumber)
PARTITION BY RANGE(l_shipdate)
(FROM ('2023-10-17') TO ('2023-10-20') INTERVAL 1 DAY)
DISTRIBUTED BY HASH(l_orderkey) BUCKETS 3
PROPERTIES ("replication_num" = "1");

INSERT INTO lineitem VALUES
(1, 2, 3, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-17', '2023-10-17', '2023-10-17', 'a', 'b',
'yyyyyyyyyy'),
(2, 2, 3, 4, 5.5, 6.5, 7.5, 8.5, 'o', 'k', '2023-10-18', '2023-10-18', '2023-10-18', 'a', 'b',
'yyyyyyyyyy'),
(3, 2, 3, 6, 7.5, 8.5, 9.5, 10.5, 'k', 'o', '2023-10-19', '2023-10-19', '2023-10-19', 'c', 'd',
'xxxxxxxxxx');

```

## Create an Asynchronous Materialized View

Based on several original tables in the tpch benchmark, create an asynchronous materialized view named mv1.

```

CREATE MATERIALIZED VIEW mv1
BUILD IMMEDIATE REFRESH COMPLETE ON MANUAL
PARTITION BY(l_shipdate)
DISTRIBUTED BY RANDOM BUCKETS 2
PROPERTIES ('replication_num' = '1')
AS
SELECT l_shipdate, o_orderdate, l_partkey, l_suppkey, SUM(o_totalprice) AS sum_total
FROM lineitem
LEFT JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate
GROUP BY
l_shipdate,
o_orderdate,
l_partkey,
l_suppkey;

```

## Use the Materialized View for Transparent Rewriting

```

mysql> explain shape plan SELECT l_shipdate, SUM(o_totalprice) AS total_price
-> FROM lineitem
-> LEFT JOIN orders ON lineitem.l_orderkey = orders.o_orderkey AND l_shipdate = o_orderdate
-> WHERE l_partkey = 2 AND l_suppkey = 3
-> GROUP BY l_shipdate;
+-----+
| Explain String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashAgg[GLOBAL] |

```

```

| -----PhysicalDistribute[DistributionSpecHash] |
| -----hashAgg[LOCAL] |
| -----PhysicalProject |
| -----filter((mv1.l_partkey = 2) and (mv1.l_supkey = 3)) |
| -----PhysicalOlapScan[mv1] |
+-----+

```

It can be seen from the `explain shape plan` that the plan after being transparently rewritten by `mv1` has already hit `mv1`. You can also use `explain` to view the current state of the plan after being rewritten by the materialized view, including whether it has hit and which materialized view has been hit, etc., as shown below:

```

| ===== MATERIALIZATIONS ===== |
| | |
| MaterializedView |
| MaterializedViewRewriteSuccessAndChose: |
| internal.tpch.mv1 chose, |
| | |
| MaterializedViewRewriteSuccessButNotChose: |
| not chose: none, |
| | |
| MaterializedViewRewriteFail: |

```

## Summary

By using `async-materialized views`, the query performance can be significantly improved, especially for complex join and aggregation queries. When using them, the following points need to be noted:

### Usage Suggestions

- **Pre-computed Results:** Materialized views pre-compute and store the query results, avoiding the overhead of repeated computations for each query. This is especially effective for complex queries that need to be executed frequently.
- **Reducing Join Operations:** Materialized views can combine the data of multiple tables into one view, reducing the join operations during queries and thus improving query efficiency.
- **Automatic Updates:** When the data in the base tables changes, materialized views can be updated automatically to maintain data consistency. This ensures that the query results always reflect the latest data status.
- **Space Overhead:** Materialized views require additional storage space to save the pre-computed results. When creating materialized views, it is necessary to balance the improvement in query performance and the consumption of storage space.
- **Maintenance Cost:** The maintenance of materialized views requires certain system resources and time. Base tables that are updated frequently may lead to relatively high update overheads for materialized views. Therefore, it is necessary to choose an appropriate refresh strategy according to the actual situation.
- **Applicable Scenarios:** Materialized views are suitable for scenarios where the data change frequency is low and the query frequency is high. For frequently changing data, real-time computation may be more appropriate. :::

Reasonable utilization of `async-materialized views` can significantly improve the query performance of the database, especially in the case of complex queries and large data volumes. Meanwhile, factors such as

storage and maintenance also need to be considered comprehensively to achieve a balance between performance and cost.

# Optimizing Join with Colocate Group

Defining colocate group is an efficient way of Join. It allows the execution engine to effectively avoid the data transmission overhead typically associated with Join operations (for an introduction to Colocate Group, see [Colocation Join](#))

However, in some use cases, even if a Colocate Group has been successfully established, the execution plan may still show as Shuffle Join or Bucket Shuffle Join. This situation typically occurs when Doris is organizing data. For instance, it may be migrating tablets between BEs to ensure a more balanced data distribution across multiple BEs.

You can view the Colocate Group status using the command `SHOW PROC "/colocation_group";`. As shown in the figure below, if `IsStable` is `false`, it indicates that there are unavailable Colocate Group instances.

```
mysql> show proc "/colocation_group";
```

| GroupId     | GroupName             | TableIds     | BucketsNum | ReplicaAllocation       | DistCols   | IsStable | ErrorMsg |
|-------------|-----------------------|--------------|------------|-------------------------|------------|----------|----------|
| 36023.36619 | 36023_part_partsupp   | 36425,36621  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 32022.34353 | 32022_lineitem_orders | 32815,34355  | 768        | tag.location.default: 1 | bigint(20) | true     |          |
| 10644.11087 | 10644_part_partsupp   | 11037,11089  | 24         | tag.location.default: 1 | int(11)    | true     |          |
| 83282.83478 | 83282_lineitem_orders | 8328483480   | 96         | tag.location.default: 1 | bigint(20) | true     |          |
| 47947.50278 | 47947_lineitem_orders | 48740,50280  | 768        | tag.location.default: 1 | bigint(20) | false    |          |
| 29082.30133 | 29082_part_partsupp   | 30083,30135  | 24         | tag.location.default: 1 | int(11)    | false    |          |
| 85801.85997 | 85801_lineitem_orders | 85803,85999  | 96         | tag.location.default: 1 | bigint(20) | true     |          |
| 10644.10840 | 10644_lineitem_orders | 10646,10842  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 47947.48543 | 47947_part_partsupp   | 48349,48545  | 96         | tag.location.default: 1 | bigint(20) | true     |          |
| 29082.29866 | 29082_lineitem_orders | 29672,29888  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 32022.32618 | 32022_part_partsupp   | 32424,32620  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 44074.46405 | 44074_lineitem_orders | 44867,46407  | 768        | tag.location.default: 1 | bigint(20) | true     |          |
| 83282.83725 | 83282_part_partsupp   | 83675,83727  | 24         | tag.location.default: 1 | int(11)    | true     |          |
| 85801.86244 | 85801_part_partsupp   | 86194,86246  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 40021.40617 | 40021_part_partsupp   | 40423,40619  | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 36023.38354 | 36023_lineitem_orders | 36816, 38356 | 768        | tag.location.default: 1 | bigint(20) | true     |          |
| 44074.44670 | 44074_part_partsupp   | 44476, 44672 | 96         | tag.location.default: 1 | int(11)    | true     |          |
| 40021.42352 | 40021_lineitem_orders | 40814, 42354 | 768        | tag.location.default: 1 | bigint(20) | true     |          |

18 rows in set (0.00 sec)

## Optimizing Join with Colocate Group

# Adjusting Join Shuffle Mode with Hint

## Overview

Doris supports the use of hints to adjust the type of data shuffle in Join operations, thereby optimizing query performance. This section provides detailed instructions on how to specify the Join Shuffle type in Doris using hints.

### Note

Currently, Doris has good out-of-the-box capabilities. This means that in most scenarios, Doris will adaptively optimize performance in various scenarios, and users do not need to manually control hints for performance tuning. The content introduced in this chapter is mainly for professional tuners, and business personnel only need a simple understanding.

Currently, Doris supports two independent [Distribute Hint](#), `[shuffle]` and `[broadcast]`, to specify the Distribute Type for the right table in a Join. The Distribute Type should be placed before the right table in the Join, enclosed in square brackets `[]`. Additionally, Doris can specify the shuffle mode by using the Leading Hint in conjunction with the Distribute Hint (for more details, refer to [Reordering Join With Leading Hint](#)).

Examples are as follows:

```
SELECT COUNT(*) FROM t2 JOIN [broadcast] t1 ON t1.c1 = t2.c2;
SELECT COUNT(*) FROM t2 JOIN [shuffle] t1 ON t1.c1 = t2.c2;
```

## Case

Next, we will demonstrate the usage of Distribute Hints through an example:

```
EXPLAIN SHAPE PLAN SELECT COUNT(*) FROM t1 JOIN t2 ON t1.c1 = t2.c2;
```

The plan for the original SQL is as follows, showing that the join between t1 and t2 uses the hash distribute method, indicated by `DistributionSpecHash`.

```
+-----+
| Explain String (Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg [GLOBAL] |
| ----PhysicalDistribute [DistributionSpecGather] |
| -----hashAgg [LOCAL] |
| -----PhysicalProject |
| -----hashJoin [INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalProject |
| -----PhysicalOlapScan [t1] |
| -----PhysicalDistribute [DistributionSpecHash] |
| -----PhysicalProject |
+-----+
```

```
| -----PhysicalOlapScan [t2] |
+-----+
+-----+
```

After adding the [broadcast] hint:

```
EXPLAIN SHAPE PLAN SELECT COUNT(*) FROM t1 JOIN [broadcast] t2 ON t1.c1 = t2.c2;
```

It can be seen that the distribution method for the join between t1 and t2 has been changed to the broadcast method, indicated by `DistributionSpecReplicated`.

```
+-----+
| Explain String (Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg [GLOBAL] |
| ----PhysicalDistribute [DistributionSpecGather] |
| -----hashAgg [LOCAL] |
| -----PhysicalProject |
| -----hashJoin [INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalProject |
| -----PhysicalOlapScan [t1] |
| -----PhysicalDistribute [DistributionSpecReplicated] |
| -----PhysicalProject |
| -----PhysicalOlapScan [t2] |
+-----+
```

## Summary

By appropriately using Distribute Hints, you can optimize the shuffle mode for Join operations and improve query performance. In practice, it is recommended to first analyze the query execution plan using EXPLAIN and then specify the appropriate shuffle type based on the actual situation.

# Control CBO Rules With Hint

## Overview

The query optimizer applies a series of rules when generating execution plans. These rules are mainly categorized into two types: Rule-Based Optimizer (RBO) and Cost-Based Optimizer (CBO).

- RBO: This type of optimization improves query plans by applying a set of predefined heuristic rules without considering specific data statistics. Strategies such as predicate pushdown and projection pushdown fall into this category.
- CBO: This type of optimization leverages data statistics to estimate the cost of different execution plans and selects the plan with the lowest cost for execution. This includes choices of access paths and join algorithms.

In some cases, database administrators or developers may need more granular control over the query optimization process. Based on this, this document will introduce how to use query hints to manage CBO rules.

### Note

Currently, Doris has good out-of-the-box capabilities. This means that in most scenarios, Doris will adaptively optimize performance in various scenarios, and users do not need to manually control hints for performance tuning. The content introduced in this chapter is mainly for professional tuners, and business personnel only need a simple understanding.

The basic syntax for CBO rule control hints is as follows:

```
SELECT /*+ USE_CBO_RULE(rule1, rule2, ...) */ ...
```

This hint immediately follows the SELECT keyword and specifies the names of the rules to be enabled within parentheses (rule names are case-insensitive).

Currently, the Doris optimizer supports several cost-based rewrites, which can be explicitly enabled using the USE\_CBO\_RULE hint, such as:

- PUSH\_DOWN\_AGG\_THROUGH\_JOIN
- PUSH\_DOWN\_AGG\_THROUGH\_JOIN\_ONE\_SIDE
- PUSH\_DOWN\_DISTINCT\_THROUGH\_JOIN

## Case

Here is a query example:

```
explain shape plan
select /*+ USE_CBO_RULE(push_down_agg_through_join_one_side) */
 a.event_id,
 b.group_id,
```

```

 COUNT(a.event_id)
 from a
 join b on
 a.device_id = b.device_id
 group by
 a.event_id,
 b.group_id
;

```

In this example, a CBO rule for aggregation pushdown is enabled. This operation allows table a to be aggregated before the join operation, reducing the cost of the join and speeding up the query. The plan after pushdown is as follows:

```

PhysicalResultSink
--hashAgg[GLOBAL]
----hashAgg[LOCAL]
-----hashJoin[INNER_JOIN] hashCondition=((a.device_id = b.device_id)) otherCondition=()
-----hashAgg[LOCAL]
-----PhysicalOlapScan[a]
-----filter((cast(experiment_id as DOUBLE) = 73.0))
-----PhysicalOlapScan[b]

```

## Summary

Proper use of the `USE_CBO_RULE` hint can help manually enable certain advanced CBO optimization rules, optimizing performance in specific scenarios. However, using CBO optimization rules requires a deep understanding of the query optimization process and data characteristics. In most cases, relying on the automatic decisions of the Doris optimizer is still the best choice.

# Reordering Join With Leading Hint

## Overview

The Leading Hint feature allows users to manually specify the join order of tables in a query, optimizing the performance of complex queries in specific scenarios. This article will describe in detail how to use Leading Hint to control the join order in Doris. For detailed usage instructions, please refer to the [leading hint](#) document.

### Note

Currently, Doris has good out-of-the-box capabilities. This means that in most scenarios, Doris will adaptively optimize performance in various scenarios, and users do not need to manually control hints for performance tuning. The content introduced in this chapter is mainly for professional tuners, and business personnel only need a simple understanding.

## Case 1: Adjusting the Left and Right Table Order

For the following query:

```
mysql> explain shape plan select * from t1 join t2 on t1.c1 = t2.c2;
+-----+
| _Explain_ String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t2] |
+-----+
```

You can use Leading Hint to force the join order to be t2 join t1 and adjust the original join order.

```
mysql> explain shape plan select /*+ leading(t2 t1) */ * from t1 join t2 on t1.c1 = t2.c2;
+-----+
| _Explain_ String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t1] |
| |
| Hint log: |
| Used: leading(t2 t1) |
| Unused: |
+-----+
```

```
| SyntaxError: |
+-----+
```

The Hint log shows the successfully applied hint: Used: leading(t2 t1).

## Case 2: Forcing the Generation of a Left-Deep Tree

```
mysql> explain shape plan select /*+ leading(t1 t2 t3) */ * from t1 join t2 on t1.c1 = t2.c2 join t3 on t2.c2
= t3.c3;
+-----+
| _Explain_ String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t3] |
| |
| Hint log: |
| Used: leading(t1 t2 t3) |
| UnUsed: |
| SyntaxError: |
+-----+
```

Similarly, the Hint log shows the successfully applied hint: Used: leading(t1 t2 t3).

## Case 3: Forcing the Generation of a Right-Deep Tree

```
mysql> explain shape plan select /*+ leading(t1 {t2 t3}) */ * from t1 join t2 on t1.c1 = t2.c2 join t3 on
t2.c2 = t3.c3;
+-----+
| _Explain_ String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute[DistributionSpecGather] |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = t2.c2)) otherCondition=() |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalOlapScan[t3] |
| |
| Hint log: |
| Used: leading(t1 { t2 t3 }) |
| UnUsed: |
| SyntaxError: |
+-----+
```

Similarly, the Hint log shows the successfully applied hint: Used: leading(t1 { t2 t3 }).

## Case 4: Forcing the Generation of a Bushy Tree

```
mysql> explain shape plan select /*+ leading({t1 t2} {t3 t4}) */ * from t1 join t2 on t1.c1 = t2.c2 join t3
on t2.c2 = t3.c3 join t4 on t3.c3 = t4.c4;
```

```
+-----+
| _Explain_ String |
+-----+
| PhysicalResultSink |
| --PhysicalDistribute |
| ----PhysicalProject |
| -----hashJoin[INNER_JOIN](t2.c2 = t3.c3) |
| -----hashJoin[INNER_JOIN](t1.c1 = t2.c2) |
| -----PhysicalOlapScan[t1] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute |
| -----hashJoin[INNER_JOIN](t3.c3 = t4.c4) |
| -----PhysicalOlapScan[t3] |
| -----PhysicalDistribute |
| -----PhysicalOlapScan[t4] |
| | |
| Used: leading({ t1 t2 } { t3 t4 }) |
| Unused: |
| SyntaxError: |
+-----+
```

Similarly, the Hint log shows the successfully applied hint: Used: leading({ t1 t2 } { t3 t4 }).

## Case 5: View Participating in the Join as a Whole

```
mysql> explain shape plan select /*+ leading(alias t1) */ count(*) from t1 join (select c2 from t2 join t3
on t2.c2 = t3.c3) as alias on t1.c1 = alias.c2;
```

```
+-----+
| _Explain_ String(Nereids Planner) |
+-----+
| PhysicalResultSink |
| --hashAgg[GLOBAL] |
| ----PhysicalDistribute[DistributionSpecGather] |
| -----hashAgg[LOCAL] |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t1.c1 = alias.c2)) otherCondition=() |
| -----PhysicalProject |
| -----hashJoin[INNER_JOIN] hashCondition=((t2.c2 = t3.c3)) otherCondition=() |
| -----PhysicalProject |
| -----PhysicalOlapScan[t2] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalProject |
| -----PhysicalOlapScan[t3] |
| -----PhysicalDistribute[DistributionSpecHash] |
| -----PhysicalProject |
| -----PhysicalOlapScan[t1] |
| | |
| Hint log: |
| Used: leading(alias t1) |
| Unused: |
| SyntaxError: |
+-----+
```

Similarly, the Hint log shows the successfully applied hint: Used: leading(alias t1).

## Case 6: Mixing DistributeHint and LeadingHint

```
explain shape plan
select
 nation,
 o_year,
 sum(amount) as sum_profit
from
 (
 select
 /*+ leading(orders shuffle {lineitem shuffle part} shuffle {supplier broadcast nation}
shuffle partsupp) */
 n_name as nation,
 extract(year from o_orderdate) as o_year,
 l_extendedprice * (1 - l_discount) - ps_supplycost * l_quantity as amount
 from
 part,
 supplier,
 lineitem,
 partsupp,
 orders,
 nation
 where
 s_suppkey = l_suppkey
 and ps_suppkey = l_suppkey
 and ps_partkey = l_partkey
 and p_partkey = l_partkey
 and o_orderkey = l_orderkey
 and s_nationkey = n_nationkey
 and p_name like '%green%'
) as profit
group by
 nation,
 o_year
order by
 nation,
 o_year desc;
```

The above hint specification `/*+ leading(orders shuffle {lineitem shuffle part} shuffle {supplier broadcast nation} shuffle partsupp) */` mixes the two formats of leading and distribute hint. Leading is used to control the relative join order among the overall tables, while shuffle and broadcast are used to specify the shuffle method for specific joins. By combining the two, the connection order and connection method can be flexibly controlled, making it convenient to manually control the expected plan behavior of the user.

### Usage Suggestions

- It is recommended to use EXPLAIN to carefully analyze the execution plan to ensure that the Leading Hint can achieve the expected effect.
- When the Doris version is upgraded or the business data changes, the effect of the Leading Hint should be re-evaluated, and timely recording and adjustment should be made.

## Summary

Leading Hint is a powerful function that can manually control the connection order. At the same time, it can also be combined with the shuffle hint to control the join distribution method at the same time, thereby optimizing the query performance. Note that this advanced feature should be used with caution based on a full understanding of the query characteristics and data distribution.

# Accelerating Queries with SQL Cache

---

## Overview

For the detailed implementation principle of SQL Cache, please refer to the chapter [SQL Cache](#).

## Case

For detailed cases, please refer to the chapter [SQL Cache](#).

## Summary

SQL Cache is a query optimization mechanism provided by Doris, which can significantly improve query performance. When using it, the following points should be noted:

### Note

- SQL Cache is not suitable for queries containing functions that generate random values (such as `random()`), as this will cause the query results to lose randomness.
- Currently, it does not support using the cached results of some metrics to meet the needs of querying more metrics. For example, the cache for previously queried two metrics cannot be used for the situation of querying three metrics.
- By reasonably using SQL Cache, the query performance of Doris can be significantly improved, especially in scenarios with a low data update frequency. In practical applications, cache parameters need to be adjusted according to specific data characteristics and query patterns to achieve the best performance improvement. :::

# DML Tuning Plan

---

For DML plan tuning, it is first necessary to identify whether the performance bottleneck is caused by the import process or the query section. For the troubleshooting and tuning of performance bottlenecks in the query section, please refer to other subsections in [Plan Tuning](#) for details.

Doris supports importing data from multiple data sources. By flexibly utilizing the various import functions provided by Doris, data from various sources can be efficiently imported into Doris for analysis. For details of best practices, please refer to [Import Overview](#).

# Adjustment of RuntimeFilter Wait Time

---

## Adjustment of RuntimeFilter Wait Time

### Overview

In actual production scenarios, there may be performance issues caused by unreasonable RuntimeFilter wait times. RuntimeFilter is a query optimization technique that generates filter conditions at runtime, thereby avoiding scanning irrelevant data. This optimization method can significantly reduce I/O operations and computational load, thus accelerating query execution. The following sections introduce several common cases to help with optimization in data skew scenarios.

### Case: Too Short RuntimeFilter Wait Time

Refer to the following Profile information:

```
OLAP_SCAN_OPERATOR (id=22. nereids_id=1764. table name = test_doris(test_doris)):(ExecTime: 62.870ms)
 - RuntimeFilters: : RuntimeFilter: (id = 6, type = minmax, need_local_merge: true,
is_broadcast: false, build_bf_cardinality: false, RuntimeFilter: (id = 7, type = in_or_bloomfilter,
need_local_merge: true, is_broadcast: false, build_bf_cardinality: false,
 - PushDownPredicates: []
 - KeyRanges: ScanKeys:ScanKey=[null(-9223372036854775808) : 9223372036854775807]
 - TabletIds: [1732763414173, 1732763414187, 1732763414201, 1732763414215]
 - UseSpecificThreadToken: False
 - AcquireRuntimeFilterTime: 969ns
 - BlocksProduced: 1.829K (1829)
 - CloseTime: 0ns
 - ExecTime: 62.870ms
 - InitTime: 75.703us
 - KeyRangesNum: 0
 - MaxScannerThreadNum: 32
 - MemoryUsage:
 - PeakMemoryUsage: 0.00
 - NumScanners: 32
 - OpenTime: 19.276ms
 - ProcessConjunctTime: 30.360us
 - ProjectionTime: 0ns
 - RowsProduced: 7.433056M (7433056)
 - RowsRead: 0
 - RuntimeFilterInfo:
 - ScannerWorkerWaitTime: 0ns
 - TabletNum: 4
 - TotalReadThroughput: 0
 - WaitForDependency[OLAP_SCAN_OPERATOR_DEPENDENCY]Time: 0ns
 - WaitForRuntimeFilter: 1000ms
 RuntimeFilter: (id = 6, type = minmax):
 - Info: [IsPushDown = false, RuntimeFilterState = NOT_READY, HasRemoteTarget = true,
HasLocalTarget = false, Ignored = false]
 RuntimeFilter: (id = 7, type = in_or_bloomfilter):
 - Info: [IsPushDown = false, RuntimeFilterState = NOT_READY, HasRemoteTarget = true,
HasLocalTarget = false, Ignored = false]
```

From the Profile, we can see that `WaitForRuntimeFilter: 1000ms`. Here, the `RuntimeFilter` waited for 1000ms, but this `ScanOperator` did not receive the corresponding `RuntimeFilter`, and `RuntimeFilterState = NOT_READY`.

```
RuntimeFilter: (id = 6, type = minmax):
 - Info: [IsPushDown = false, RuntimeFilterState = NOT_READY, HasRemoteTarget = true,
HasLocalTarget = false, Ignored = false]
RuntimeFilter: (id = 7, type = in_or_bloomfilter):
 - Info: [IsPushDown = false, RuntimeFilterState = NOT_READY, HasRemoteTarget = true,
HasLocalTarget = false, Ignored = false]
```

So, the corresponding `RuntimeFilters` with ids 6 and 7 were not received. By locating the `Join` that generates the `RuntimeFilter` through the Profile, we found that the `Join` took time:

```
HASH_JOIN_OPERATOR (id=26, nereids_id=37948):
 - PlanInfo
 - join op: RIGHT OUTER JOIN(PARTITIONED)[]
 - equal join conjunct: (id = ID)
 - runtime filters: RF006[min_max] <- ID(6418/8192/1048576), RF007[in_or_bloom] <-
ID(6418/8192/1048576)
 - cardinality=6,418
 - vec output tuple id: 27
 - output tuple id: 27
 - vIntermediate tuple ids: 25
 - hash output slot ids: 396 398 399 400 401 402 403 404 405 406 407 408 409 410 411 412
413 447
 - projections: USER_ID
 - project output tuple id: 27
 - BlocksProduced: sum 1, avg 1, max 1, min 1
 - CloseTime: avg 10.111us, max 10.111us, min 10.111us
 - ExecTime: avg 364.497us, max 364.497us, min 364.497us
 - InitTime: avg 26.653us, max 26.653us, min 26.653us
 - MemoryUsage: sum, avg, max, min
 - PeakMemoryUsage: sum 0.00, avg 0.00, max 0.00, min 0.00
 - ProbeKeyArena: sum 0.00, avg 0.00, max 0.00, min 0.00
 - OpenTime: avg 45.985us, max 45.985us, min 45.985us
 - ProbeRows: sum 0, avg 0, max 0, min 0
 - ProjectionTime: avg 211.930us, max 211.930us, min 211.930us
 - RowsProduced: sum 1, avg 1, max 1, min 1
 - WaitForDependency[HASH_JOIN_OPERATOR_DEPENDENCY]Time: avg 1sec780ms, max 1sec780ms, min
1sec780ms
```

It can be seen that this `Join` took approximately 1sec780ms, so the `RuntimeFilter` did not wait in 1s. Therefore, the `RuntimeFilter` wait time was adjusted:

```
set runtime_filter_wait_time_ms = 3000;
```

After the adjustment, the query time was reduced from 5s to 2s.

## Summary

The wait time of `RuntimeFilter` needs to be defined according to the scenario. Doris is undergoing some adaptive optimization and transformation. Use the `EXPLAIN` and `PROFILE` tools to observe the execution bottleneck, locate the corresponding problem, and modify the `RuntimeFilter` wait time through SQL Hint to avoid the impact of the corresponding problem on performance.

# Data Skew Handling

## Data Skew Handling

### Overview

Doris is an MPP database that relies on data shuffle for parallel computing acceleration. However, in actual production scenarios, performance bottlenecks in single threads of query parallelism are often encountered due to data skew. The following sections introduce how to identify such problems and provide some general solutions.

### Case 1: Bucket Data Skew Leading to Suboptimal Shuffle Method

When data skew occurs on the Join Key of a table, the data will be unevenly distributed among different BE instances, resulting in a single-point execution bottleneck and thus slowing down the overall query execution time.

```
HASH_JOIN_OPERATOR (id=27):
- PlanInfo
 - join op: INNER JOIN(PARTITIONED)[]
 - equal join conjunct: (customer_number = customer_number)
 - runtime filters: RF001[bloom] <- customer_number(200/256/2048)
 - cardinality=200
 - vec output tuple id: 28
 - output tuple id: 28
 - vIntermediate tuple ids: 27
 - hash output slot ids: 192 193 194 195 196 197 198 199 200 201 174 175 240 176
177 178 179 180 181 182 183 184 185 186 187 188 189 190 191
 - project output tuple id: 28
- BlocksProduced: sum 4.883K (4883), avg 33, max 39, min 29
- CloseTime: avg 37.28us, max 132.653us, min 13.945us
- ExecTime: avg 166.206ms, max 10s947.344ms, min 8.845ms
- InitTime: avg 0ns, max 0ns, min 0ns
- MemoryUsage: sum , avg , max , min
 - PeakMemoryUsage: sum 11.81 MB, avg 84.00 KB, max 84.00 KB, min 84.00 KB
 - ProbeKeyArena: sum 11.81 MB, avg 84.00 KB, max 84.00 KB, min 84.00 KB
- OpenTime: avg 194.970us, max 497.685us, min 93.738us
- ProbeRows: sum 23.884018M (23884018), avg 165.861K (165861), max 219.346276M (219346276),
min 1984 (1984)
- ProjectionTime: avg 7.336ms, max 33.540ms, min 3.760ms
- RowsProduced: sum 28.8K (28800), avg 200, max 200, min 200
```

From the max indicators in the above Join's Profile, there is an obvious skew in the execution time and ProbeRows.

```
ExecTime: avg 166.206ms, max 10s947.344ms, min 8.845ms
ProbeRows: sum 23.884018M (23884018), avg 165.861K (165861), max 219.346276M (219346276), min 1984 (1984)
```

However, due to the uneven distribution of data after shuffling based on the join key, one thread may process 200 million rows of data while another thread only processes a few thousand rows. In the ideal case of the

above scenario, each thread should process approximately the same amount of data. But due to the data skew problem of the Join column, a large amount of computational work may be completed by a single thread. To solve this performance bottleneck, refer to the tuning techniques mentioned in the “Using Hint to Control Join Shuffle Method” section and specify the broadcast join hint as follows to prevent the left table from shuffling data, thus effectively avoiding the performance bottleneck caused by data skew on the Join column.

```
SELECT COUNT(*) FROM orders o JOIN [broadcast] customer c ON o.customer_number = c.customer_number;
```

## Case 2: Column Data Skew Leading to Reversed Join Sides

The current Doris optimizer estimates the selectivity based on the assumption of uniform data distribution. Large deviations in the estimated number of rows after filtering can affect the operator’s plan selection. Take the following SQL as an example:

```
select count(*)
from orders, customer
where o_custkey = c_custkey
and o_orderdate < '1920-01-02';
```

Under the assumption of uniform distribution, the optimizer may think that the number of rows output after filtering by `o_orderdate < '1920-01-02'` will be less than the number of rows in the customer table. Therefore, it may choose the join order of customer join orders. However, if the actual data is skewed and the number of rows in the orders table that satisfy the condition is greater than that in the customer table, then a more reasonable join order should be orders join customer. To solve this performance problem, refer to the tuning techniques mentioned in the “Using Leading Hint to Control Join Order” section and specify the leading hint as follows to force the generation of the join order of customer join orders.

Rewrite the SQL as follows:

```
select /*+leading(orders customer)*/ count(*)
from orders, customer
where o_custkey = c_custkey
and o_orderdate < '1920-01-02'
```

## Summary

Data skew is a common performance problem in production scenarios. By observing the plan and execution bottlenecks through the EXPLAIN and PROFILE tool outputs, locating the cause of the skew, and then using the Hint tool to make corresponding plan adjustments, the impact of data skew on performance can be avoided.

# Parallelism Tuning

---

## Overview

Doris queries are executed in an MPP (Massively Parallel Processing) framework, where each query is executed in parallel across multiple BEs (Backend Executors). Meanwhile, within a single BE, a multi-threaded parallel approach is adopted to enhance query execution efficiency. Currently, all types of statements, including queries, DML (Data Manipulation Language), and DDL (Data Definition Language), support parallel execution.

The control parameter for parallelism within a single BE is `parallel_pipeline_task_num`, which refers to the number of working tasks used by a single Fragment during execution. In actual production scenarios, performance issues may arise due to improper parallelism settings. The following examples illustrate cases of optimizing parallelism.

## Principles of Parallelism Tuning

The purpose of setting `parallel_pipeline_task_num` is to fully utilize multi-core resources and reduce query latency. However, to enable multi-core parallel execution, some data shuffle operators and synchronization logic between multiple threads are usually introduced, which may also lead to unnecessary resource wastage.

The default value in Doris is 0, which is half the number of CPU cores of the BE. This value takes into account the resource utilization of both single queries and concurrent operations, and usually does not require user intervention for adjustment. When there is a performance bottleneck, refer to the following examples for necessary adjustments. Doris is continuously improving its adaptive strategy, and it is usually recommended to make necessary adjustments in specific scenarios or at the SQL level.

Suppose the BE has 16 CPU cores:

1. For simple operations on a single table (such as single-table point queries, WHERE clause scans to retrieve a small amount of data, LIMIT a small amount of data, or hitting a materialized view), **the parallelism can be set to 1.**

Explanation: Simple operations on a single table involve only one Fragment. The bottleneck of such queries usually lies in data scanning and processing. The data scanning thread and the query execution thread are separated, and the data scanning thread will perform parallel scanning adaptively. Here, the bottleneck is not the query thread, so the parallelism can be directly set to 1.

2. For queries involving two-table JOIN or aggregation queries, if the data volume is large and it is confirmed to be a CPU-bound query, **the parallelism can be set to 16.**

Explanation: For two-table JOIN or aggregation queries, which are data computation-intensive queries, if the CPU is not fully utilized, consider increasing the parallelism on the basis of the default value to take advantage of the parallel capabilities of the Pipeline execution engine and fully utilize CPU resources for computation. It cannot be guaranteed that each PipelineTask can utilize the allocated CPU resources to the fullest. Therefore, the parallelism can be adjusted appropriately, for example, set to 16, to make better use of the CPU. However, the parallelism should not be increased indefinitely. Setting it to 48 will

not bring substantial benefits and will instead increase thread scheduling overhead and framework scheduling overhead.

3. In a stress testing scenario, where the multiple queries in the stress test can fully utilize the CPU, **the parallelism can be set to 1**.

Explanation: In a stress testing scenario, there are sufficient query tasks. Excessive parallelism also brings thread scheduling overhead and framework scheduling overhead. Setting it to 1 is more reasonable in this case.

4. For complex queries, the parallelism should be adjusted flexibly based on the Profile and machine load. Here, it is recommended to use the default value. If it is not suitable, a stepwise adjustment of 4-2-1 can be tried, and the query performance and machine load should be observed.

## Methods of Parallelism Tuning

Doris allows users to manually specify the parallelism of a query to adjust the parallel execution efficiency during query execution.

### SQL Level Adjustment

Use SQL HINT to specify the parallelism of a single SQL statement. This allows for flexible control of the parallelism of different SQL statements to achieve the best execution results.

```
select /**SET_VAR("parallel_pipeline_task_num=8")*/ * from nation, lineitem where lineitem.l_suppkey = nation.n_nationkey
select /**SET_VAR("parallel_pipeline_task_num=8, runtime_filter_mode=global")*/ * from nation, lineitem where lineitem.l_suppkey = nation.n_nationkey
```

### Session Level Adjustment

Adjust the parallelism at the session level through session variables. All query statements in the session will be executed with the specified parallelism. Please note that even single-line SQL queries will use this parallelism, which may lead to performance degradation.

```
set parallel_pipeline_task_num = 8;
```

### Global Adjustment

If global adjustment is required, usually involving CPU utilization adjustment, the parallelism can be set globally.

```
set global parallel_pipeline_task_num = 8;
```

## Tablets and parallelism

Since version 2.1, Doris supports decoupling parallelism from the number of tablets.

In previous versions, parallelism could not exceed the number of tablets involved in the query. For example, if a query involved 5 tablets, the maximum scan concurrency was only 5. This could prevent some large tablets from being read concurrently.

In the new version, Doris supports concurrent reads within a shard. This feature is enabled automatically and requires no user configuration.

Note that this feature only supports the Duplicate and Unique Key Merge-On-Write table models. It does not apply to the Aggregate and Unique Key Merge-On-Read models. For these two models, query parallelism is still constrained by the number of tablets.

## Best Practice

### Case 1: High Parallelism Leading to High CPU Usage in a High-Concurrency Pressure Scenario

When observing high CPU usage online, which affects the performance of some low-latency queries, consider adjusting the query parallelism to reduce CPU usage. Since Doris's design philosophy is to prioritize using more resources to obtain query results as quickly as possible, in some scenarios with tight online resources, this may lead to poor performance. Therefore, appropriate adjustment of parallelism can improve the overall stability and efficiency of queries under limited resources.

Set the parallelism from the default value of 0 (half the number of CPU cores) to 4:

```
set global parallel_pipeline_task_num = 4;
```

After the global setting, it takes effect for the current connection and new connections. Existing other connections are not affected. If immediate global effect is required, the FE (Frontend) can be restarted. After the adjustment, the CPU usage is reduced to 60% of the previous peak value, reducing the impact on some low-latency queries.

### Case 2: Increasing Parallelism to Further Utilize the CPU for Query Acceleration

The current default parallelism in Doris is half the number of CPU cores, and some computation-intensive scenarios cannot fully utilize the CPU for query acceleration.

```
select sum(if(t2.value is null, 0, 1)) exist_value, sum(if(t2.value is null, 1, 0)) no_exist_value
from t1 left join t2 on t1.key = t2.key;
```

In a scenario with 2 billion rows in the left table and 5 million rows in the right table, the above SQL takes 28 seconds to execute. Observe the Profile:

```
HASH_JOIN_OPERATOR (id=3, nereids_id=448):
- PlanInfo
 - join op: LEFT OUTER JOIN(BROADCAST)[]
 - equal join conjunct: (value = value)
 - cardinality=2,462,330,332
 - vec output tuple id: 5
 - output tuple id: 5
 - vIntermediate tuple ids: 4
```

```

- hash output slot ids: 16
- projections: value
- project output tuple id: 5
- BlocksProduced: sum 360.099K (360099), avg 45.012K (45012), max 45.014K (45014), min
45.011K (45011)
- CloseTime: avg 8.44us, max 13.327us, min 5.574us
- ExecTime: avg 26sec153ms, max 26sec261ms, min 26sec33ms
- InitTime: avg 7.122us, max 13.395us, min 4.541us
- MemoryUsage: sum, avg, max, min
 - PeakMemoryUsage: sum 1.16 MB, avg 148.00 KB, max 148.00 KB, min 148.00 KB
 - ProbeKeyArena: sum 1.16 MB, avg 148.00 KB, max 148.00 KB, min 148.00 KB
- OpenTime: avg 2.967us, max 4.120us, min 1.562us
- ProbeRows: sum 1.462330332B (1462330332), avg 182.791291M (182791291), max 182.811875M
(182811875), min 182.782658M (182782658)
- ProjectionTime: avg 165.392ms, max 169.762ms, min 161.727ms
- RowsProduced: sum 1.462330332B (1462330332), avg 182.791291M (182791291), max 182.811875M
(182811875), min 182.782658M (182782658)

```

The main time-consuming part here: ExecTime: avg 26sec153ms, max 26sec261ms, min 26sec33ms all occurs in the Join operator, and the total amount of data processed: ProbeRows: sum 1.4662330332B is 1.4 billion, which is a typical CPU-intensive computation scenario. Observing the machine monitoring, it is found that the CPU resources are not fully utilized, with a CPU utilization rate of 60%. At this time, consider increasing the parallelism to further utilize the idle CPU resources for acceleration.

Set the parallelism as follows:

```
set parallel_pipeline_task_num = 16;
```

The query execution time is reduced from 28 seconds to 19 seconds, and the CPU utilization rate is increased from 60% to 90%.

## Summary

Usually, users do not need to adjust the query parallelism. If adjustment is required, the following points should be noted:

1. It is recommended to start from the CPU utilization. Observe whether it is a CPU bottleneck through the PROFILE tool output and try to make reasonable modifications to the parallelism.
2. Adjusting a single SQL is relatively safe. Try not to make overly aggressive global modifications.

# Common Tuning Parameters

---

| Parameter                  | Description                                         | Default Value | Usage Scenario                                                                                                                                                                                                  |
|----------------------------|-----------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable_nereids_planner     | Whether to enable the new optimizer                 | TRUE          | For scenarios such as low-version upgrades, initially set to false; after upgrading, it can be set to true                                                                                                      |
| enable_nereids_dml         | Whether to enable DML support for the new optimizer | TRUE          | For scenarios such as low-version upgrades, initially set to false; after upgrading, it can be set to true                                                                                                      |
| parallel_pipeline_task_num | Pipeline parallelism                                | 0             | For scenarios such as low-version upgrades, this value was previously set to a fixed value; after upgrading, it can be set to 0, indicating that the system's adaptive strategy determines the parallelism      |
| runtime_filter_mode        | Runtime Filter type                                 | GLOBAL        | For scenarios such as low-version upgrades, this value was NONE, indicating that Runtime Filter was not enabled; after upgrading, it can be set to GLOBAL, indicating that Runtime Filter is enabled by default |

# Query Optimizers

---

In the current information technology landscape, query optimizers face multiple challenges: on the one hand, they need to handle increasingly complex query statements and diverse query scenarios from users; on the other hand, users have increasingly strict demands for query real-time performance, desiring instant access to required results. Furthermore, to address emerging new requirements, query optimizers must possess the capabilities of rapid iteration and flexible adaptation.

Based on this background, Doris embarked on the development of a brand-new query optimizer. Leveraging a modern optimizer architecture, this optimizer aims to more efficiently tackle query requests in the current Doris scenarios while providing exceptional scalability, laying a solid foundation for potentially more complex future demands.

## Advantages of the Optimizer

### Smarter

The optimizer clearly presents each optimization point of RBO (Rule-Based Optimization) and CBO (Cost-Based Optimization) in the form of rules. For each rule, the optimizer provides a set of patterns that describe the shape of the query plan, enabling precise matching of optimizable query plans. Therefore, the optimizer can better support more complex query statements such as nested multi-layer subqueries.

Meanwhile, the optimizer's CBO is based on the advanced Cascades framework, fully utilizing rich statistical data, data characteristic information, and a meticulously tuned cost model. This empowers the optimizer to handle complex queries like multi-table joins with ease and proficiency.

### More Stable

All optimization rules of the optimizer are executed on the logical execution plan tree. After parsing the query syntax and semantics, the query is transformed into a tree structure. Compared to the old optimizer, the new optimizer's internal data structure is more reasonable and unified.

Taking subquery processing as an example, the new optimizer, based on its new data structure, avoids the separate handling of subqueries by numerous rules in the old optimizer, thereby reducing the likelihood of logical errors in optimization rules.

### More Flexible

The optimizer's architecture is reasonably and modernly designed, making it very convenient to extend optimization rules and processing stages. Therefore, we can swiftly add new functionalities to meet evolving new requirements.

## Principles of the Optimizer

### Principles of the Optimizer

The execution process of the optimizer is divided into the following steps:

1. **Syntax Analysis:** The optimizer attempts to convert the SQL text into an Abstract Syntax Tree (AST). If the SQL text is valid, it proceeds to the next steps; if invalid, it reports an error and terminates execution.
2. **Semantic Analysis:** The optimizer performs semantic analysis on the elements in the AST. This step checks whether tables, columns, functions, etc., in the SQL query exist and whether their usage complies with syntax and semantic rules. If the semantics are valid, execution continues; if invalid, it reports an error and terminates execution.
3. **Rewrite Query Plan (RBO):** After syntax and semantic analysis, the optimizer performs Rule-Based Optimization (RBO). This step rewrites the query plan through a series of predefined rules to deterministically optimize execution speed. Common optimization techniques include column pruning, predicate pushdown, partition pruning, etc.
4. **Optimize Query Plan (CBO):** Finally, the optimizer performs Cost-Based Optimization (CBO). In this step, the optimizer enumerates equivalent plan sets in the search space and evaluates their execution costs. By comparing the execution costs of different plans, the optimizer selects the plan with the lowest cost as the final execution plan. This step aims to ensure that queries are executed in the most efficient manner, thereby providing optimal performance.

## Session Variables

### 1. Set Planning Timeout `nerheids_timeout_second`

- This variable is used to set the maximum allowed time for query planning. When the planning time exceeds this set value, query planning will be terminated, and an error message will be returned. During the process of planning query statements, the system obtains read locks for all tables involved in the

SQL, primarily to maintain cluster stability and prevent excessive resource occupation and lock conflicts caused by excessively long planning times.

- Default value: 30s
- Applicable scenarios: When queries involve a large number of external tables or particularly complex query statements, this value can be appropriately increased to ensure that queries can proceed normally.

# Parallel Execution

---

The parallel execution model of Doris is a Pipeline execution model, primarily inspired by the implementation described in the [Hyper](#) paper. The Pipeline execution model fully leverages the computational power of multi-core CPUs while limiting the number of query threads in Doris, addressing the issue of thread explosion during execution. For details on its design, implementation, and effectiveness, refer to [DSIP-027](#) and [DSIP-035](#).

Starting from Doris 3.0, the Pipeline execution model has completely replaced the original Volcano model. Based on the Pipeline execution model, Doris supports the parallel processing of Query, DDL, and DML statements.

## Physical Plan

To better understand the Pipeline execution model, it is first necessary to introduce two important concepts in the physical query plan: PlanFragment and PlanNode. We will use the following SQL statement as an example:

```
SELECT k1, SUM(v1) FROM A,B WHERE A.k2 = B.k2 GROUP BY k1 ORDER BY SUM(v1);
```

FE will first translate it into the following logical plan, each node represents a PlanNode. The detail meaning of each node type can be found in the introduction of physical plan.

pip\_exec\_1

Since Doris is built on an MPP architecture, each query aims to involve all BEs in parallel execution as much as possible to reduce query latency. Therefore, the logical plan must be transformed into a physical plan. The transformation essentially involves inserting DataSink and ExchangeNode into the logical plan. These two nodes facilitate the shuffling of data across multiple BEs.

After the transformation, each PlanFragment corresponds to a portion of the PlanNode and can be sent as an independent task to a BE. Each BE processes the PlanNode contained within the PlanFragment and then uses the DataSink and ExchangeNode operators to shuffle data to other BEs for subsequent computation.

pip\_exec\_2

Doris's plan is divided into three layers:

- **PLAN:** The execution plan. A SQL statement is translated by the query planner into an execution plan, which is then provided to the execution engine for execution.
- **FRAGMENT:** Since Doris is a distributed execution engine, a complete execution plan is divided into multiple single-machine execution fragments. A FRAGMENT represents a complete single-machine execution fragment. Multiple fragments combine to form a complete PLAN.
- **PLAN NODE:** Operators, which are the smallest units of the execution plan. A FRAGMENT consists of multiple operators, each responsible for a specific execution logic, such as aggregation or join operations.

## Pipeline Execution

A PlanFragment is the smallest unit of a task sent by the FE to the BE for execution. A BE may receive multiple different PlanFragments for the same query, and each PlanFragment is processed independently. Upon receiving a PlanFragment, the BE splits it into multiple Pipelines and then starts multiple PipelineTasks to achieve parallel execution, thereby improving query efficiency.

pip\_exec\_3

## Pipeline

Pipeline consists of a SourceOperator, a SinkOperator, and several intermediate operators. The SourceOperator represents reading data from an external source, which can be a table (e.g., OlapTable) or a buffer (e.g., Exchange). The SinkOperator represents the data output, which can either be shuffled to other nodes over the network (e.g., DataStreamSinkOperator) or output to a hash table (e.g., aggregation operators, join build hash tables, etc.).

pip\_exec\_4

Multiple Pipelines are actually interdependent. Take the JoinNode as an example—it is split into two Pipelines. Pipeline-0 reads data from Exchange to build the hash table, while Pipeline-1 reads data from the table to perform the probe operation. These two Pipelines are connected by a dependency relationship, meaning Pipeline-1 can only execute after Pipeline-0 has completed. This dependency relationship is referred to as a Dependency. Once Pipeline-0 finishes execution, it calls the `set_ready` method of the Dependency to notify Pipeline-1 that it is ready to execute.

## PipelineTask

Pipeline is actually a logical concept; it is not an executable entity. Once a Pipeline is defined, it needs to be further instantiated into multiple PipelineTasks. The data that needs to be read is then distributed to different PipelineTasks, ultimately achieving parallel processing. The operators within the multiple PipelineTasks of the same Pipeline are identical, but they differ in their states. For example, they might read different data or build different hash tables. These differing states are referred to as LocalState.

Each PipelineTask is eventually submitted to a thread pool to be executed as an independent task. With the Dependency trigger mechanism, this approach allows better utilization of multi-core CPUs and achieves full parallelism.

## Operator

In most cases, each operator in a Pipeline corresponds to a PlanNode, but there are some special operators with exceptions: \* JoinNode is split into JoinBuildOperator and JoinProbeOperator. \* AggNode is split into AggSinkOperator and AggSourceOperator. \* SortNode is split into SortSinkOperator and SortSourceOperator. The basic principle is that for certain “breaking” operators (those that need to collect all the data before performing computation), the data ingestion part is split into a Sink, while the part that retrieves data from the operator is referred to as the Source.

## Parallel Scan

Scanning data is a very heavy I/O operation, as it requires reading large amounts of data from local disks (or from HDFS or S3 in the case of data lake scenarios, which introduces even longer latency), consuming a significant amount of time. Therefore, we have introduced parallel scanning technology in the ScanOperator. The ScanOperator dynamically generates multiple Scanners, each of which scans around 1 to 2 million rows of data. While performing the scan, each Scanner handles tasks such as data decompression, filtering, and other calculations, and then sends the data to a DataQueue for the ScanOperator to read.

pip\_exec\_5

By using parallel scanning technology, we can effectively avoid issues where certain ScanOperators take an excessively long time due to improper bucketing or data skew, which would otherwise slow down the entire query latency.

## Local Shuffle

In the Pipeline execution model, Local Shuffle acts as a Pipeline Breaker, a technique that redistributes data locally across different execution tasks. It evenly distributes all the data output by the upstream Pipeline to all the tasks in the downstream Pipeline using methods like HASH or Round Robin. This helps solve the problem of data skew during execution, ensuring that the execution model is no longer limited by data storage or the query plan. Let's now provide an example to illustrate how Local Exchange works.

We will further explain how Local Exchange can prevent data skew using Pipeline-1 from the previous example.

pip\_exec\_6

As shown in the figure above, by inserting a Local Exchange in Pipeline-1, we further split Pipeline-1 into Pipeline-1-0 and Pipeline-1-1.

Now, let's assume the current concurrency level is 3 (each Pipeline has 3 tasks), and each task reads one bucket from the storage layer. The number of rows in the three buckets is 1, 1, and 7, respectively. The execution before and after inserting the Local Exchange changes as follows:

`pip_exec_7`

As can be seen from the figure on the right, the amount of data that the HashJoin and Agg operators need to process changes from (1, 1, 7) to (3, 3, 3), thereby avoiding data skew.

Local Shuffle is planned based on a series of rules. For example, when a query involves time-consuming operators like Join, Aggregation, or Window Functions, Local Shuffle is used to minimize data skew as much as possible.

# Runtime Filter

---

Runtime Filter mainly consists of two types: Join Runtime Filter and TopN Runtime Filter. This article will provide a detailed introduction to the working principles, usage guidelines, and tuning methods of these two types of Runtime Filters.

## Join Runtime Filter

Join Runtime Filter (hereinafter referred to as JRF) is an optimization technique that dynamically generates filters at the Join node based on runtime data, leveraging the Join condition. This technique not only reduces the size of the Join Probe but also effectively minimizes data I/O and network transmission.

### Principles

Let's illustrate the working principle of JRF using a Join operation similar to that found in the TPC-H Schema.

Assume there are two tables in the database:

- Orders Table: Contains 100 million rows of data, recording order keys (o\_orderkey), customer keys (o\_custkey), and other order information.
- Customer Table: Contains 100,000 rows of data, recording customer keys (c\_custkey), customer nations (c\_nation), and other customer information. This table records customers from 25 countries, with approximately 4,000 customers per country.

To count the number of orders from customers in China, the query statement would be:

```
select count(*)
from orders join customer on o_custkey = c_custkey
where c_nation = "china"
```

The main component of the execution plan for this query is a Join, as illustrated below:

## Join Runtime Filter

Without JRF: The Scan node scans the orders table, reading 100 million rows of data. The Join node then performs a Hash Probe on these 100 million rows to generate the Join result.

### 1. Optimization

The filter condition `c_nation = 'china'` filters out all non-Chinese customers, so only a portion (approximately 1/25) of the customer table is involved in the Join. Given the subsequent Join condition `o_custkey = c_custkey`, we need to focus on the `c_custkey` values selected in the filtered result. Let's denote the filtered `c_custkey` values as set A. In the following text, we use set A specifically to refer to the `c_custkey` set participating in the Join.

If set A is pushed down to the orders table as an IN condition, the Scan node for the orders table can filter the orders accordingly. This is similar to adding a filter condition `o_custkey IN (c001, c003)`.

Based on this optimization concept, SQL can be optimized to:

```
select count(*)
from orders join customer on o_custkey = c_custkey
where c_nation = "china" and o_custkey in (c001, c003)
```

The optimized execution plan is illustrated below:

join-runtime-filter-2

By adding a filter condition on the orders table, the actual number of orders participating in the Join is reduced from 100 million to 400,000, significantly improving query speed.

## 2. Implementation

While the optimization described above is significant, the optimizer does not know the actual `c_custkey` values selected (set A) and thus cannot statically generate a fixed in-predicate filter operator during the optimization phase.

In practical applications, we collect the right-side data at the Join node, generate set A at runtime, and push down set A to the Scan node of the orders table. We typically denote this JRF as:  $RF(c\_custkey \rightarrow [o\_custkey])$ .

As Doris is a distributed database, JRF requires an additional merging step to cater to distributed scenarios. Assuming the Join in the example is a Shuffle Join, multiple instances of this Join handle individual shards of the orders and customer tables. Consequently, each Join instance only obtains a portion of set A.

In the current version of Doris, we select a node to serve as the Runtime Filter Manager. Each Join instance generates a Partial JRF based on the `c_custkey` values in its shard and sends it to the Manager. The Manager collects all Partial JRFs, merges them into a Global JRF, and then sends the Global JRF to all Scan instances of the orders table.

The process of generating the Global JRF is illustrated below:

Global JRF

## Filter Types

There are various data structures that can be employed to implement JRF (Join Runtime Filter), each with varying efficiencies in generation, merging, transmission, and application, making them suitable for different scenarios.

### 1. In Filter

The simplest approach to implementing JRF is through the use of an In Filter. Taking the previous example, when using an In Filter, the execution engine generates a predicate `o_custkey in (...list of elements in Set A...)` on the left table. This In filter condition can then be applied to filter the orders table. When the number of elements in Set A is small, the In Filter is efficient.

However, using an In Filter becomes problematic when the number of elements in Set A is large:

1. Firstly, the cost of generating an In Filter is high, especially when JRF merging is required. Values collected from Join nodes corresponding to different data partitions may contain duplicates. For instance, if `c_custkey` is not the primary key of the table, values like `c001` and `c003` could appear multiple times, necessitating a time-consuming deduplication process.
2. Secondly, when Set A contains many elements, the cost of transmitting data between the Join node and the Scan node of the orders table is significant.
3. Lastly, executing the In predicate at the Scan node of the orders table also takes time.

Considering these factors, we introduce the Bloom Filter.

## 2. Bloom Filter

For those unfamiliar with Bloom Filters, they can be thought of as a set of superimposed hash tables. Using a Bloom Filter (or hash table) for filtering leverages the following property:

- A hash table T is generated based on Set A. If an element is not in hash table T, it can be definitively concluded that the element is not in Set A. However, the reverse is not true.

Therefore, if an `o_orderkey` is filtered out by the Bloom Filter, it can be concluded that there is no matching `c_custkey` on the right side of the Join. Nevertheless, due to hash collisions, some `o_custkeys` may pass through the Bloom Filter even if there is no matching `c_custkey`.

While a Bloom Filter cannot achieve precise filtering, it still provides a certain level of filtering effectiveness.

- The number of buckets in the hash table determines the accuracy of filtering. The larger the number of buckets, the larger and more accurate the Filter becomes, but at the cost of increased computational overhead in generation, transmission, and usage.

Therefore, the size of the Bloom Filter must strike a balance between filtering effectiveness and usage costs. To this end, we have set a configurable range for the Bloom Filter's size, defined by `RUNTIME_BLOOM_FILTER_MIN_SIZE` and `RUNTIME_BLOOM_FILTER_MAX_SIZE`.

## 3. Min/Max Filter

Apart from the Bloom Filter, the Min-Max Filter can also be used for approximate filtering. If the data column is ordered, the Min-Max Filter can achieve excellent filtering results. Additionally, the costs of generating, merging, and using a Min-Max Filter are significantly lower than those of an In Filter or Bloom Filter.

For non-equi Joins, both In Filters and Bloom Filters become ineffective, but the Min-Max Filter can still function. Suppose we modify the query from the previous example to:

```
select count(*)
from orders join customer on o_custkey > c_custkey
where c_name = "China"
```

In this case, we can select the maximum filtered `c_custkey`, denote it as `n`, and pass it to the Scan node of the orders table. The Scan node will then only output rows where `o_custkey > n`.

## Viewing Join Runtime Filter

To see which JRFs (Join Runtime Filters) have been generated for a specific query, you can use the `explain`, `explain shape plan`, or `explain physical plan` commands.

Using the TPC-H Schema as an example, we will detail how to view JRFs using these three commands.

```
select count(*) from orders join customer on o_custkey=c_custkey;
```

## 1. Explain

In traditional Explain output, JRF information is typically displayed in Join and Scan nodes, as shown in the following example:

```

4: VHASH JOIN(258)
| join op: INNER JOIN(PARTITIONED)[]
| equal join conjunct: (o_custkey[#10] = c_custkey[#0])
| runtime filters: RF000[bloom] <- c_custkey[#0] (150000000/134217728/16777216)
| cardinality=1,500,000,000
| vec output tuple id: 3
| output tuple id: 3
| vIntermediate tuple ids: 2
| hash output slot ids: 10
| final projections: o_custkey[#17]
| final project output tuple id: 3
| distribute expr lists: o_custkey[#10]
| distribute expr lists: c_custkey[#0]
|
|---1: VEXCHANGE
| offset: 0
| distribute expr lists: c_custkey[#0]
3: VEXCHANGE
| offset: 0
| distribute expr lists:

PLAN FRAGMENT 2
| PARTITION: HASH_PARTITIONED: o_orderkey[#8]
| HAS_COLO_PLAN_NODE: false
| STREAM DATA SINK
| EXCHANGE ID: 03
| HASH_PARTITIONED: o_custkey[#10]

2: V0lapScanNode(242)
| TABLE: regression_test_nereids_tpch_shape_sf1000_p0.orders(orders)
| PREAGGREGATION: ON
| runtime filters: RF000[bloom] -> o_custkey[#10]
| partitions=1/1 (orders)
| tablets=96/96, tabletList=54990,54992,54994 ...
| cardinality=0, avgRowSize=0.0, numNodes=1
| pushAggOp=NONE

```

- Join Side: runtime filters: RF000[bloom] <- c\_custkey[#0] (150000000/134217728/16777216)

This indicates that a Bloom Filter with ID 000 has been generated, using c\_custkey as input to create the JRF. The three numbers following are related to Bloom Filter size calculations and can be ignored for now.

- Scan Side: runtime filters: RF000[bloom] -> o\_custkey[#10]

This indicates that JRF 000 will be applied to the Scan node of the orders table, filtering the o\_custkey field.

## 2. Explain Shape Plan

In the Explain Plan series, we'll use Shape Plan as an example to show how to view JRFs.

```

mysql> explain shape plan select count(*) from orders join customer on o_custkey=c_custkey where
c_nationkey=5;
+-----

```

```

-----+
Explain String(Nereids Planner)
|
+-----+
PhysicalResultSink
|
--hashAgg[GLOBAL]
|
----PhysicalDistribute[DistributionSpecGather]
|
-----hashAgg[LOCAL]
|
-----PhysicalProject
|
-----hashJoin[INNER_JOIN shuffle]
|
-----hashCondition=((orders.o_custkey=customer.c_custkey)) otherCondition=() buildRFs:RF0 c_custkey->
[o_custkey] |
-----PhysicalProject
|
-----Physical0lapScan[orders] apply RFs: RF0
|
-----PhysicalProject
|
-----filter((customer.c_nationkey=5))
|
-----Physical0lapScan[customer]
|
+-----+
11 rows in set (0.02 sec)

```

As shown above:

- Join Side: build RFs: RF0 c\_custkey -> [o\_custkey] indicates that JRF 0 is generated using c\_custkey data and applied to o\_custkey.
- Scan Side: Physical0lapScan[orders] apply RFs: RF0 indicates that orders table is filtered by JRF 0.

### 3. Profile

During actual execution, BE outputs JRF usage details to the Profile (requires set enable\_profile=true). Using the same SQL query as an example, we can view JRF execution details in the Profile.

- Join Side

```

HASH_JOIN_SINK_OPERATOR (id=3 , nereids_id=367):(ExecTime: 703.905us)
- JoinType: INNER_JOIN
...
- BuildRows: 617
...
- RuntimeFilterComputeTime: 70.741us
- RuntimeFilterInitTime: 10.882us

```

This is the Build side Profile for the Join. In this example, generating the JRF took 70.741us with 617 rows of input data. The JRF size and type are shown on the Scan side.

- Scan Side

```
OLAP_SCAN_OPERATOR (id=2. nereids_id=351. table name = orders(orders)):(ExecTime: 13.32ms)
 - RuntimeFilters: : RuntimeFilter: (id = 0, type = bloomfilter,
need_local_merge: false, is_broadcast: true, build_bf_cardinality: false,
 ...
 - RuntimeFilterInfo:
 - filter id = 0 filtered: 714.761K (714761)
 - filter id = 0 input: 747.862K (747862)
 ...
 - WaitForRuntimeFilter: 6.317ms
RuntimeFilter: (id = 0, type = bloomfilter):
 - Info: [IsPushDown = true, RuntimeFilterState = READY, HasRemoteTarget =
false, HasLocalTarget = true, Ignored = false]
 - RealRuntimeFilterType: bloomfilter
 - BloomFilterSize: 1024
```

Note:

1. Lines 5-6 show the input rows and the number of filtered rows. A higher number of filtered rows indicates better JRF effectiveness.
2. Line 10, IsPushDown = true, indicates that JRF computation has been pushed down to the storage layer, which can help reduce IO through delayed materialization.
3. Line 10, RuntimeFilterState = READY, indicates whether the Scan node has applied the JRF. Since JRF uses a try-best mechanism, if JRF generation takes too long, the Scan node may start scanning data after a waiting period, potentially outputting unfiltered data.
4. Line 12, BloomFilterSize: 1024, shows the size of the Bloom Filter in bytes.

## Tuning

For Join Runtime Filter tuning, in most cases, the function is adaptive, and users do not need to manually tune it. However, there are a few adjustments that can be made to optimize performance.

### 1. Enable or Disable JRF

The session variable `runtime_filter_mode` controls whether JRFs are generated.

- To enable JRF: set `runtime_filter_mode = GLOBAL`
- To disable JRF: set `runtime_filter_mode = OFF`

### 2. Set JRF Type

The session variable `runtime_filter_type` controls the type of JRFs, including:

- IN(1)
- BLOOM(2)
- MIN\_MAX(4)
- IN\_OR\_BLOOM(8)

The IN\_OR\_BLOOM Filter allows BE to adaptively choose between generating an IN Filter or a BLOOM Filter based on the actual number of rows of data.

Multiple JRF types can be generated for a single Join condition by setting `runtime_filter_type` to the sum of the corresponding enumeration values.

For example:

- To generate both a BLOOM Filter and a MIN\_MAX Filter for each Join condition: set `runtime_filter_type = 6`
- In version 2.1, the default value of `runtime_filter_type` is 12, which generates both a MIN\_MAX Filter and an IN\_OR\_BLOOM Filter.

The integers in parentheses represent the enumeration values for Runtime Filter Types.

### 3. Set Wait Time

As mentioned earlier, JRF uses a Try-best mechanism, where Scan nodes wait for JRFs before starting. Doris calculates the wait time based on runtime conditions. However, in some cases, the calculated wait time may not be sufficient, resulting in JRFs not being fully effective, and the Scan nodes may output more rows than expected. As discussed in the Profile section, if `RuntimeFilterState = NOT_READY` in the Scan node's Profile, users can manually set a longer wait time.

The session variable `runtime_filter_wait_time_ms` controls the wait time for Scan nodes to wait for JRFs. The default value is 1000 milliseconds.

### 4. Pruning JRF

In some cases, JRFs may not provide filtering benefits. For example, if the orders and customer tables have a primary-foreign key relationship, but there are no filtering conditions on the customer table, the input to the JRF would be all custkeys, allowing all rows in the orders table to pass through the JRF. The optimizer prunes ineffective JRFs based on column statistics.

The session variable `enable_runtime_filter_prune = true/false` controls whether pruning is performed. The default value is `true`.

## TopN Runtime Filter

### Principles

In Doris, data is processed in a block-streaming manner. Therefore, when an SQL statement includes a topN operator, Doris does not compute all results but instead generates a dynamic filter to pre-filter the data early on.

Consider the following SQL statement as an example:

```
select o_orderkey from orders order by o_orderdate limit 5;
```

The execution plan for this SQL statement is illustrated below:

```
mysql> explain select o_orderkey from orders order by o_orderdate limit 5;
```

```
+-----+
| Explain String(Nereids Planner) |
+-----+
| PLAN FRAGMENT 0 |
| OUTPUT EXPRS: |
| o_orderkey[#11] |
| PARTITION: UNPARTITIONED |
| |
| HAS_COLO_PLAN_NODE: false |
| |
| VRESULT SINK |
| MYSQL_PROTOCOL |
| |
| 2:VMERGING-EXCHANGE |
| offset: 0 |
| limit: 5 |
| final projections: o_orderkey[#9] |
| final project output tuple id: 2 |
| distribute expr lists: |
| |
| PLAN FRAGMENT 1 |
| |
| PARTITION: HASH_PARTITIONED: O_ORDERKEY[#0] |
| |
| HAS_COLO_PLAN_NODE: false |
| |
| STREAM DATA SINK |
| EXCHANGE ID: 02 |
| UNPARTITIONED |
| |
| 1:VTOP-N(119) |
	order by: o_orderdate[#10] ASC
	TOPN OPT
	offset: 0
	limit: 5
	distribute expr lists: O_ORDERKEY[#0]
0:VOlapScanNode(113)	
TABLE: tpch.orders(orders), PREAGGREGATION: ON	
TOPN OPT:1	
partitions=1/1 (orders)	
tablets=3/3, tabletList=135112,135114,135116	
cardinality=150000, avgRowSize=0.0, numNodes=1	
pushAggOp=NONE	
+-----+
41 rows in set (0.06 sec)
```

Without a topn filter, the scan node would sequentially read each data block from the orders table and pass them to the TopN node. The TopN node maintains the current top 5 rows from the orders table through heap sorting.

Since a data block typically contains around 1024 rows, the TopN node can identify the 5th ranked row within the first data block after processing it.

Assuming this o\_orderdate is 1995-01-01, the scan node can then use 1995-01-01 as a filter condition when outputting the second data block, eliminating the need to send rows with o\_orderdate greater than 1995-01-01 to the TopN node for further processing.

This threshold is dynamically updated. For instance, if the TopN node discovers a smaller o\_orderdate when processing the second filtered data block, it updates the threshold to the fifth-ranked o\_orderdate among the first two data blocks.

## Viewing TopN Runtime Filter

Using the Explain command, we can inspect the TopN Runtime Filter planned by the optimizer.

```
1:VTOP-N(119)
| order by: o_orderdate[#10] ASC
| TOPN OPT
| offset: 0
| limit: 5
| distribute expr lists: O_ORDERKEY[#0]
|

0:VLapScanNode[113]
 TABLE: regression_test_nereids_tpch_p0.(orders), PREAGGREGATION: ON
 TOPN OPT: 1
 partitions=1/1 (orders)
 tablets=3/3, tabletList=135112,135114,135116
 cardinality=150000, avgRowSize=0.0, numNodes=1
 pushAggOp: NONE
```

As shown in the example above:

1. The TopN node displays TOPN OPT, indicating that this TopN node generates a TopN Runtime Filter.
2. The Scan node indicates which TopN node generates the TopN Runtime Filter it uses. For instance, in the example, line 11 indicates that the Scan node for the orders table will use the Runtime Filter generated by TopN node 1, shown as TOPN OPT: 1 in the plan.

As a distributed database, Doris considers the physical machines where TopN and Scan nodes actually run. Due to the high cost of cross-BE communication, BEs adaptively decide whether and to what extent to use TopN Runtime Filters. Currently, we have implemented BE-level TopN Runtime Filters, where TopN and Scan reside on the same BE. This is because updating TopN Runtime Filter thresholds only requires inter-thread communication, which is relatively inexpensive.

## Tuning

The session variable topn\_filter\_ratio controls whether to generate a TopN Runtime Filter.

The fewer rows specified in the SQL's limit clause, the stronger the filtering effect of the TopN Runtime Filter. Therefore, by default, Doris enables the generation of corresponding TopN Runtime Filters only when the limit number is less than half of the data in the table.

For example, setting set topn\_filter\_ratio=0 would prevent the generation of a TopN Runtime Filter for the following query:

```
select o_orderkey from orders order by o_orderdate limit 20;
```

# TOPN Query Optimization

---

TOPN queries refer to queries that involve ORDER BY LIMIT operations, which are common in log retrieval and other detailed query scenarios. Doris automatically optimizes this type of query.

```
SELECT * FROM tablex WHERE xxx ORDER BY c1,c2 ... LIMIT n
```

## Advantages of TOPN

1. During execution, dynamic range filters are built for the sorting columns (e.g.,  $c1 \geq 1000$ ), which automatically apply the preceding conditions when reading data, leveraging zonemap indexes to filter out some rows or even entire files.
2. If the sorting fields  $c1$ ,  $c2$  are exactly the prefix of the table key, further optimization is applied. When reading data, only the header or tail of the data files is read, reducing the amount of data read to just the  $n$  rows needed.
3. SELECT \* deferred materialization, during the data reading and sorting process, only the sorting columns are read, not the other columns. After obtaining the row numbers that meet the conditions, the entire data of those  $n$  rows needed is read, significantly reducing the amount of data read and sorted.

## Limitations

1. It only applies to DUP and MOW tables, not to MOR and AGG tables.
2. Due to the high memory consumption on very large  $n$ , it will not take effect if  $n$  is greater than `topn_opt_limit_threshold`.

## Configuration and Query Analysis

The following two parameters are session variables that can be set for a specific SQL or globally.

1. `topn_opt_limit_threshold`: This session variable determines whether TOPN optimization is applied. It defaults to 1024, and setting it to 0 disables the optimization.
2. `enable_two_phase_read_optimization`: This session variable determines whether to enable this optimization. It defaults to true, and setting it to false disables the optimization.
3. `topn_filter_ratio`, the ratio between LIMIT  $n$  and the total data in the table, the default value is 0.5, which means that if the number of LIMIT is more than half of the data in the table, no filter will be generated.

## Checking if TOPN Query Optimization is Enabled

To confirm if TOPN query optimization is enabled for a particular SQL, you can use the EXPLAIN statement to get the query plan. An example is as follows:

- TOPN OPT indicates that optimization point 1 is applied.
- V0lapScanNode with SORT LIMIT indicates optimization point 2 is applied.
- OPT TWO PHASE indicates optimization point 3 is applied.

```
1:VTOP-N(137)
| order by: @timestamp18 DESC
| TOPN OPT
| OPT TWO PHASE
| offset: 0
| limit: 10
| distribute expr lists: applicationName5
|
0:V0lapScanNode(106)
 TABLE: log_db.log_core_all_no_index(log_core_all_no_index), PREAGGREGATION: ON
 SORT INFO:
 @timestamp18
 SORT LIMIT: 10
 TOPN OPT:1
 PREDICATES: ZYCFC-TRACE-ID4 like '%flowId-1720055220933%'
 partitions=1/8 (p20240704), tablets=250/250, tabletList=1727094,1727096,1727098 ...
 cardinality=345472780, avgRowSize=0.0, numNodes=1
 pushAggOp=NONE
```

## Checking the Effectiveness of TOPN Query Optimization During Execution

First, set `topn_opt_limit_threshold` to 0 to disable TOPN query optimization and compare the execution time of the SQL with and without optimization enabled.

After enabling TOPN query optimization, search for `RuntimePredicate` in the query profile and focus on the following metrics:

- `RowsZonemapRuntimePredicateFiltered`: The number of rows filtered out, the higher the better.
- `NumSegmentFiltered`: The number of data files filtered out, the higher the better.
- `BlockConditionsFilteredZonemapRuntimePredicateTime`: The time taken to filter data, the lower the better.

Before version 2.0.3, the `RuntimePredicate` metrics were not separated out, and the `Zonemap` metrics can be used as a rough guide.

```
SegmentIterator:
- BitmapIndexFilterTimer: 46.54us
- BlockConditionsFilteredBloomFilterTime: 10.352us
- BlockConditionsFilteredDictTime: 7.299us
- BlockConditionsFilteredTime: 202.23ms
- BlockConditionsFilteredZonemapRuntimePredicateTime: 0ns
- BlockConditionsFilteredZonemapTime: 402.917ms
- BlockInitSeekCount: 399
- BlockInitSeekTime: 11.309ms
- BlockInitTime: 215.59ms
- BlockLoadTime: 7s567ms
- BlocksLoad: 392.97K (392970)
- CachedPagesNum: 0
- CollectIteratorMergeTime: 0ns

# Statistics | Optimization Technology Principle

---

## Statistics

Starting from version 2.0, Doris integrated Cost-Based Optimization (CBO) capabilities into its optimizer. Statistics are the cornerstone of CBO, and their accuracy directly determines the accuracy of cost estimation, which is crucial for selecting the optimal execution plan. This document serves as a guide to statistical usage for unreleased development version, focusing on the collection and management methods, relevant configuration options, and frequently asked questions.

### Collection of Statistics

Doris enables the automatic sampling collection of internal tables by default. Therefore, in most cases, users don't need to pay attention to the collection of statistical information. Doris collects statistics at the column level for each table. The information collected includes:

| Info of Statistics | Description                              |
|--------------------|------------------------------------------|
| row_count          | Total number of rows                     |
| data_size          | Total data size of the column            |
| avg_size_byte      | Average data size per row for the column |
| ndv                | Number of distinct values                |
| min                | Minimum value                            |
| max                | Maximum value                            |
| null_count         | Number of null values                    |

Currently, the system only supports collecting statistics for columns of basic data types, including BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, LARGEINT, FLOAT, DOUBLE, DATE, DATETIME, STRING, VARCHAR, TEXT, among others.

Columns of complex types, such as JSONB, VARIANT, MAP, STRUCT, ARRAY, HLL, BITMAP, TIME, TIMEV2, are skipped.

Statistics can be collected manually or automatically, and the results are stored in the `internal.__internal_schema.column_statistics` table. The following sections detail these two collection methods.

### Manual Collection

Doris allows users to manually trigger the collection and update of statistics by submitting an ANALYZE statement.

## 1. Syntax

```
ANALYZE < TABLE table_name > | < DATABASE db_name >
 [(column_name [, ...])]
 [[WITH SYNC] [WITH SAMPLE PERCENT | ROWS]];
```

Parameters Explanation:

- `table_name`: Specifies the target table for which statistics will be collected.
- `column_name`: Specifies the target columns for which statistics will be collected. These columns must exist in `table_name`, and multiple column names are separated by commas. If no column names are specified, statistics will be collected for all columns in the table.
- `sync`: Optional parameter to collect statistics synchronously. If specified, the result will be returned after collection is complete; if not specified, the operation will be performed asynchronously, and a JOB ID will be returned, which can be used to check the status of the collection task.
- `sample percent | rows`: Optional parameter for sampling during statistics collection. Allows specifying a sampling percentage or number of rows. If `WITH SAMPLE` is not specified, a full table scan will be performed. For large tables (e.g., over 5 GiB), sampling is generally recommended from a cluster resource utilization perspective. To ensure the accuracy of statistics, it is recommended to sample at least 4 million rows.

## 2. Examples

Collect statistics for all columns in the `lineitem` table:

```
ANALYZE TABLE lineitem;
```

Collect statistics for all columns in all tables in the `tpch100` database:

```
ANALYZE DATABASE tpch100;
```

Collect statistics for the `l_orderkey` and `l_linenumber` columns in the `lineitem` table by sampling 100,000 rows (note: the correct syntax should be used `WITH SAMPLE ROWS` or `WITH SAMPLE PERCENT`):

```
ANALYZE TABLE lineitem WITH SAMPLE ROWS 100000;
```

## Automatic Collection

Automatic collection is supported from version 2.0.3 onwards and is enabled by default throughout the day. Users can control the feature's activation or deactivation by setting the `ENABLE_AUTO_ANALYZE` variable:

```
SET GLOBAL ENABLE_AUTO_ANALYZE = TRUE; // Enable automatic collection
SET GLOBAL ENABLE_AUTO_ANALYZE = FALSE; // Disable automatic collection
```

When enabled, a background thread periodically scans all tables in the `InternalCatalog` within the cluster. For tables requiring statistics collection, the system automatically creates and executes collection jobs without

manual intervention.

To avoid excessive resource usage for collection wide tables' statistics, tables with more than 300 columns are not automatically collected by default. Users can adjust this threshold by modifying the session variable `auto_analyze_table_width_threshold`:

```
SET GLOBAL auto_analyze_table_width_threshold = 350;
```

The default polling interval for automatic collection is 5 minutes (adjustable via the `auto_check_statistics_in_minutes` configuration in `fe.conf`). The first iteration starts 5 minutes after cluster startup. After all tables requiring collection are processed, the background thread sleeps for 5 minutes before starting the next iteration. Therefore, there is no guarantee that a table will have its statistics collected within 5 minutes, as the time to iterate through all tables can vary based on the number and size of tables.

When a table is polled, the system first determines if statistical collection is required. If so, a collection job is created and executed; otherwise, the table is skipped. Statistics collection is required if:

1. The table has columns without statistics.
2. The table's health is below the threshold (default 90, adjustable via `table_stats_health_threshold`).  
Health indicates the percentage of data that has remained unchanged since the last statistics collection: 100 indicates no change; 0 indicates all changes; a health below 90 indicates significant deviation in current statistics, necessitating re-collection.

To reduce background job overhead and improve collection speed, automatic collection uses sampling by default, sampling 4,194,304 ( $2^{22}$ ) rows. Users can adjust the sampling size by modifying `huge_table_default_sample_rows` for more accurate data distribution information.

To prevent automatic collection jobs from interfering with business operations, users can specify the execution window for automatic collection based on their requirements by setting `auto_analyze_start_time` and `auto_analyze_end_time`:

```
SET GLOBAL auto_analyze_start_time = "03:00:00"; // Set the start time to 3 AM
SET GLOBAL auto_analyze_end_time = "14:00:00"; // Set the end time to 2 PM
```

## External Table Collection

External tables typically include Hive, Iceberg, JDBC, and other types.

- **Manual Collection:** Hive, Iceberg, and JDBC tables support manual statistics collection. Hive tables support both full and sampled collection, while Iceberg and JDBC tables only support full collection. Other external table types do not support manual collection.
- **Automatic Collection:** Currently, only Hive tables are supported.

External Catalogs do not participate in automatic collection by default because they often contain large amounts of historical data, which could consume excessive resources during automatic collection. However, you can enable or disable automatic collection for an external Catalog by setting its properties:

```
ALTER CATALOG external_catalog SET PROPERTIES ('enable.auto.analyze'='true'); // Enable automatic collection
ALTER CATALOG external_catalog SET PROPERTIES ('enable.auto.analyze'='false'); // Disable automatic
collection
```

External tables do not have the concept of health. When automatic collection is enabled for a Catalog, the system defaults to collecting statistics for an external table only once every 24 hours to avoid frequent collection. You can adjust the minimum collection interval for external tables using the `external_table_auto_analyze_interval_in_millis` variable.

By default, external tables do not collect statistics, but for Hive and Iceberg tables, the system attempts to obtain row count information through the Hive Metastore and Iceberg API.

### 1. For Hive Tables:

Doris first attempts to retrieve `numRows` or `totalSize` information from the Hive table's Parameters:

- If `numRows` is found, its value is used as the table's row count.
- If `numRows` is not found but `totalSize` is available, the row count is estimated based on the table's schema and `totalSize`.
- If `totalSize` is also unavailable, by default, the system will estimate the number of rows based on the file size corresponding to the Hive table and its Schema. If there are concerns that obtaining the file size may consume excessive resources, this function can be disabled by setting the following variables.

```
SET GLOBAL enable_get_row_count_from_file_list = FALSE
```

### 2. For Iceberg Tables:

Doris calls the Iceberg snapshot API to retrieve `total-records` and `total-position-deletes` information to calculate the table's row count.

### 3. For Paimon Tables:

Doris calls Paimon's scan API to obtain the number of rows contained in each Split and calculate the row count of the table by summing up the rows of the Splits.

### 4. For JDBC Tables:

Doris sends SQL of reading table statistics to remote database to get table row count. This can only be achieved when the remote database has collected the row count information of the table. Currently, Doris supports retrieving the row count of tables in MySQL, Oracle, PostgreSQL and SQLServer.

### 5. For Other External Tables:

Automatic row count acquisition and estimation are currently not supported.

Users can view the estimated row count for external tables using the following command (see [Viewing Table Statistics Overview](#) for more detail):

```
SHOW table stats table_name;
```

- If row\_count displays as -1, row count information could not be obtained or the table is empty.

## Statistics Job Management

### Viewing Statistics Jobs

Use SHOW ANALYZE to view information about statistics collection jobs. Currently, the system retains information for only 20,000 historical jobs. Note that only information for asynchronous jobs can be viewed using this command; synchronous jobs (using WITH SYNC) do not retain historical job information.

#### 1. Syntax:

```
SHOW [AUTO] ANALYZE < table_name | job_id >
[WHERE STATE = < "PENDING" | "RUNNING" | "FINISHED" | "FAILED" >];
```

- AUTO: Displays information about historical automatic collection jobs. If unspecified, displays information about manual ANALYZE historical jobs.
- table\_name: Table name, specifying which allows you to view statistics job information for that table. Can be in the form db\_name.table\_name. If unspecified, returns information about all statistics jobs.
- job\_id: Statistics job ID, obtained when executing an asynchronous ANALYZE collection. If unspecified, the command returns information about all statistics jobs.

#### 2. Output:

Includes the following columns:

| Column Name   | Description                                   |
|---------------|-----------------------------------------------|
| job_id        | Statistics job ID                             |
| catalog_name  | Catalog name                                  |
| db_name       | Database name                                 |
| tbl_name      | Table name                                    |
| col_name      | List of column names (index_name:column_name) |
| job_type      | Job type                                      |
| analysis_type | Statistics type                               |
| message       | Job information                               |
| state         | Job state                                     |
| progress      | Job progress                                  |
| schedule_type | Scheduling type                               |
| start_time    | Job start time                                |
| end_time      | Job end time                                  |

#### 3. Example:

```
mysql show analyze 245073\G;
***** 1. row *****
 job_id: 93021
 catalog_name: internal
 db_name: tpch
 tbl_name: region
 col_name: [region:r_regionkey,region:r_comment,region:r_name]
 job_type: MANUAL
 analysis_type: FUNDAMENTALS
 message:
 state: FINISHED
 progress: 3 Finished | 0 Failed | 0 In Progress | 3 Total
 schedule_type: ONCE
 start_time: 2024-07-11 15:15:00
 end_time: 2024-07-11 15:15:33
```

## Viewing Statistics Tasks

Each collection job can contain one or more tasks, with each task corresponding to the collection of a single column. Users can view the completion status of statistics collection for each column using the following command.

### 1. Syntax:

```
SHOW ANALYZE TASK STATUS [job_id]
```

### 2. Example:

```
mysql> show analyze task status 93021;
+-----+-----+-----+-----+-----+-----+-----+
| task_id | col_name | index_name | message | last_state_change_time | time_cost_in_ms | state |
+-----+-----+-----+-----+-----+-----+-----+
93022	r_regionkey	region		2024-07-11 15:15:33	32883	FINISHED
93023	r_comment	region		2024-07-11 15:15:33	32883	FINISHED
93024	r_name	region		2024-07-11 15:15:33	32883	FINISHED
+-----+-----+-----+-----+-----+-----+-----+
```

## Viewing Statistics

Users can view collected column statistics using the `SHOW COLUMN STATS` command.

### 1. Syntax:

```
SHOW COLUMN [cached] STATS table_name [(column_name [, ...])];
```

Where:

- `cached`: Displays statistics currently cached in the FE memory.
- `table_name`: Target table for which statistics were collected, can be in the form `db_name.table_name`.
- `column_name`: Specified target column, must exist in `table_name`, multiple column names separated by commas. If unspecified, displays information for all columns.

2. Example:

```
mysql> show column stats region (r_regionkey)\G
***** 1. row *****
column_name: r_regionkey
index_name: region
count: 5.0
ndv: 5.0
num_null: 0.0
data_size: 20.0
avg_size_byte: 4.0
min: 0
max: 4
method: FULL
type: FUNDAMENTALS
trigger: MANUAL
query_times: 0
updated_time: 2024-07-11 15:15:33
1 row in set (0.36 sec)
```

Viewing Table Statistics Overview

Use SHOW TABLE STATS to view an overview of table statistics collection.

1. Syntax:

```
SHOW TABLE STATS table_name;
```

Where: table\_name: Target table name, can be in the form db\_name.table\_name.

2. Output:

Includes the following columns:

| Column Name   | Description                                                                          |
|---------------|--------------------------------------------------------------------------------------|
| updated_rows  | Number of rows updated in the table since the last ANALYZE                           |
| query_times   | Reserved column, for recording the number of queries on the table in future versions |
| row_count     | Number of rows in the table (may not reflect the exact count at command execution)   |
| updated_time  | Time of the last statistics update                                                   |
| columns       | Columns for which statistics have been collected                                     |
| trigger       | Method by which statistics were triggered                                            |
| new_partition | Whether there are new partitions with first-time data imports                        |
| user_inject   | Whether statistics were manually injected by the user                                |

3. Example:

```
mysql> show column stats region (r_regionkey)\G
***** 1. row *****
column_name: r_regionkey
index_name: region
```

```
count: 5.0
ndv: 5.0
num_null: 0.0
data_size: 20.0
avg_size_byte: 4.0
min: 0
max: 4
method: FULL
type: FUNDAMENTALS
trigger: MANUAL
query_times: 0
updated_time: 2024-07-11 15:15:33
1 row in set (0.36 sec)
```

## Killing Statistics Jobs

Use `KILL ANALYZE` to terminate a currently running asynchronous statistics job.

### 1. Syntax:

```
KILL ANALYZE job_id;
```

Where: `job_id`: The ID of the statistics job. This is the value returned when executing an asynchronous statistics collection with `ANALYZE` or obtained using the `SHOW ANALYZE` statement.

### 2. Example:

Terminate the statistics job with ID 52357.

```
mysql> KILL ANALYZE 52357;
```

## Deleting Statistics

If a Catalog, Database, or Table is deleted, users do not need to manually delete its statistics as the background process will periodically clean up this information.

However, for tables that still exist, the system does not automatically clear their statistics. In this case, users need to manually delete them using the following syntax:

```
DROP STATS table_name
```

## Session Variables and Configuration Options

### Session Variables

| Session Variable                     | Description                                          | Default Value |
|--------------------------------------|------------------------------------------------------|---------------|
| <code>auto_analyze_start_time</code> | Start time for automatic statistics collection       | 0:00:00       |
| <code>auto_analyze_end_time</code>   | End time for automatic statistics collection         | 23:59:59      |
| <code>enable_auto_analyze</code>     | Whether to enable automatic collection functionality | TRUE          |

| Session Variable                    | Description                                                                                                                                                                         | Default Value                       |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| huge_table_default_sample_rows      | Number of rows to sample for large tables                                                                                                                                           | 4194304                             |
| table_stats_health_threshold        | Value range 0-100, indicating the percentage of data updated since the last statistics collection (100 - table_stats_health_threshold)% at which statistics are considered outdated | 90                                  |
| auto_analyze_table_width_thresh old | Controls the maximum table width for automatic statistics collection, tables exceeding this column count do not participate in automatic statistics collection                      | 300                                 |
| enable_get_row_count_from_file_list | Whether to estimate row counts for Hive tables based on file sizes                                                                                                                  | FALSE (TRUE by default after 2.1.5) |

## FE Configuration

### Note

The following FE configuration options typically do not require special attention.

| FE Configuration Option                    | Description                                                                 | Default Value           |
|--------------------------------------------|-----------------------------------------------------------------------------|-------------------------|
| analyze_record_limit                       | Controls the number of persistent rows for statistics job execution records | 20000                   |
| stats_cache_size                           | Number of statistics entries cached on the FE side                          | 500000                  |
| statistics_simultaneously_running_task_num | Number of asynchronous statistics jobs that can run simultaneously          | 3                       |
| statistics_sql_mem_limit_in_bytes          | Controls the amount of BE memory each statistics SQL can occupy             | 2L * 1024 * 1024 (2GiB) |

## FAQs

### Q1: How can I check if statistics have been collected for a table and if the content is correct?

First, execute `show column stats table_name` to see if there are any statistical outputs.

Next, execute `show column cached stats table_name` to check if the statistics for the table are loaded into the cache.

```
mysql> show column stats test_table\G
Empty set (0.02 sec)

mysql> show column cached stats test_table\G
Empty set (0.00 sec)
```

The empty result indicates that there are currently no statistics for the `test_table`. If statistics exist, the result will be similar to the following:

```
mysql> show column cached stats mvTestDup;
```

| column_name<br>type | index_name<br>trigger | count<br>query_times | ndv<br>updated_time | num_null | data_size | avg_size_byte | min | max  | method |
|---------------------|-----------------------|----------------------|---------------------|----------|-----------|---------------|-----|------|--------|
| key1                | mvTestDup             | 6.0                  | 4.0                 | 0.0      | 48.0      | 8.0           | 1   | 1001 | FULL   |
| FUNDAMENTALS        | MANUAL                | 0                    | 2024-07-22 10:53:25 |          |           |               |     |      |        |
| key2                | mvTestDup             | 6.0                  | 4.0                 | 0.0      | 48.0      | 8.0           | 2   | 2001 | FULL   |
| FUNDAMENTALS        | MANUAL                | 0                    | 2024-07-22 10:53:25 |          |           |               |     |      |        |
| value2              | mvTestDup             | 6.0                  | 4.0                 | 0.0      | 24.0      | 4.0           | 4   | 4001 | FULL   |
| FUNDAMENTALS        | MANUAL                | 0                    | 2024-07-22 10:53:25 |          |           |               |     |      |        |

| FUNDAMENTALS        | MANUAL                | 0                    | 2024-07-22 10:53:25 |          |           |               |     |      |        |
| value3              | mvTestDup             | 6.0                  | 4.0                 | 0.0      | 24.0      | 4.0           | 5   | 5001 | FULL   |
| FUNDAMENTALS        | MANUAL                | 0                    | 2024-07-22 10:53:25 |          |           |               |     |      |        |

6 rows in set (0.00 sec)

If statistics exist, you can manually execute SQL queries to verify their accuracy.

```
Select count(1), ndv(col1), min(col1), max(col1) from table
```

If the errors in count and ndv are within an order of magnitude, the accuracy is generally acceptable.

## Q2: Why are statistics not being automatically collected for a table?

First, check if automatic collection is enabled:

```
Show variables like "enable_auto_analyze"; // If false, set it to true:
```

```
Set global enable_auto_analyze = true
```

If it's already true, check the number of columns in the table. If it exceeds the `auto_analyze_table_width_threshold`, the table will not participate in automatic collection. Modify this value to be greater than the current number of columns in the table:

```
Show variables like "auto_analyze_table_width_threshold"
```

```
// If the value is less than the width of the table, you can modify it:
```

```
Set global auto_analyze_table_width_threshold=350
```

If the number of columns does not exceed the threshold, execute `show auto analyze` to check if there are other collection tasks running (in the running state). Since automatic collection is executed serially by a single thread, the execution cycle may be long as it polls all databases and tables.

### Q3: Why are statistics not available for some columns?

Currently, the system only supports collecting statistics for columns of basic data types. For complex types such as JSONB, VARIANT, MAP, STRUCT, ARRAY, HLL, BITMAP, TIME, and TIMEV2, the system skips them.

### Q4: Error: “Stats table not available, please make sure your cluster status is normal”

This error typically indicates that the internal statistics table is in an unhealthy state.

First, check if all BEs (Backend) in the cluster are in a normal state and ensure they are all functioning correctly.

Next, execute the following statement to retrieve all tabletIds (first column of the output):

```
show tablets from internal.__internal_schema.column_statistics;
```

Then, check each tablet's status using its tablet\_id:

```
ADMIN DIAGNOSE TABLET tablet_id
```

If any tablets are found to be abnormal, repair them first before re-collecting statistics.

### Q5: How can I address the issue of untimely statistics collection?

The interval for automatic collection is uncertain and depends on the number and size of tables in the system. In urgent cases, manually execute an analyze operation on the table.

If automatic collection is not triggered after importing large amounts of data, consider adjusting the table\_stats\_health\_threshold parameter. Its default value is 90, meaning that automatic collection is triggered when more than 10% (100 - 90) of the table's data changes. You can increase this value, for example, to 95, so that statistics are recollected when more than 5% of the table's data changes.

### Q6: How can I address excessive resource usage during automatic collection?

Automatic collection uses sampling and does not require full table scans, and the tasks are executed serially by a single thread. Usually, system resource usage is manageable and does not impact normal query tasks.

For some special tables, such as those with many partitions or large individual tablets, memory usage may be higher.

It is recommended to plan the number of tablets reasonably when creating tables to avoid creating oversized tablets. If the tablet structure is not easily adjustable, consider enabling automatic collection or manually collecting statistics for large tables during off-peak hours to avoid impacting business operations. In the Doris 3.x series, we will optimize for such scenarios.

# Lakehouse Overview

---

The lakehouse is a modern big data solution that combines the advantages of data lakes and data warehouses. It integrates the low cost and high scalability of data lakes with the high performance and strong data governance capabilities of data warehouses, enabling efficient, secure, and quality-controlled storage and processing analysis of various data in the big data era. Through standardized open data formats and metadata management, it unifies **real-time** and **historical** data, **batch processing**, and **stream processing**, gradually becoming the new standard for enterprise big data solutions.

## Doris Lakehouse Solution

Doris provides an excellent lakehouse solution for users through an extensible connector framework, a compute-storage decoupled architecture, a high-performance data processing engine, and data ecosystem openness.

doris lakehouse architecture

## Flexible Data Access

Doris supports mainstream data systems and data format access through an extensible connector framework and provides unified data analysis capabilities based on SQL, allowing users to easily perform cross-platform data queries and analysis without moving existing data. For details, refer to [Catalog Overview](#)

## Data Source Connectors

Whether it's Hive, Iceberg, Hudi, Paimon, or database systems supporting the JDBC protocol, Doris can easily connect and efficiently access data.

For lakehouse systems, Doris can obtain the structure and distribution information of data tables from metadata services such as Hive Metastore, AWS Glue, and Unity Catalog, perform reasonable query planning, and utilize the MPP architecture for distributed computing.

For details, refer to each catalog document, such as [Iceberg Catalog](#)

## Extensible Connector Framework

Doris provides a good extensibility framework to help developers quickly connect to unique data sources within enterprises, achieving fast data interoperability.

Doris defines three levels of standard Catalog, Database, and Table, allowing developers to easily map to the required data source levels. Doris also provides standard interfaces for metadata service and storage service accessing, and developers only need to implement the corresponding interface to complete the data source connection.

Doris is compatible with the Trino Connector plugin, allowing the Trino plugin package to be directly deployed to the Doris cluster, and with minimal configuration, the corresponding data source can be accessed. Doris has already completed connections to data sources such as [Kudu](#), [BigQuery](#), and [Delta Lake](#). You can also [adapt new plugins yourself](#).

## Convenient Cross-Source Data Processing

Doris supports creating multiple data catalogs at runtime and using SQL to perform federated queries on these data sources. For example, users can associate query fact table data in Hive with dimension table data in MySQL:

```
SELECT h.id, m.name
FROM hive.db.hive_table h JOIN mysql.db.mysql_table m
ON h.id = m.id;
```

Combined with Doris's built-in [job scheduling](#) capabilities, you can also create scheduled tasks to further simplify system complexity. For example, users can set the result of the above query as a routine task executed every hour and write each result into an Iceberg table:

```
CREATE JOB schedule_load
ON SCHEDULE EVERY 1 HOUR DO
INSERT INTO iceberg.db.ice_table
SELECT h.id, m.name
FROM hive.db.hive_table h JOIN mysql.db.mysql_table m
ON h.id = m.id;
```

## High-Performance Data Processing

As an analytical data warehouse, Doris has made numerous optimizations in lakehouse data processing and computation and provides rich query acceleration features:

- Execution Engine

The Doris execution engine is based on the MPP execution framework and Pipeline data processing model, capable of quickly processing massive data in a multi-machine, multi-core distributed environment. Thanks to fully vectorized execution operators, Doris leads in computing performance in standard benchmark datasets like TPC-DS.

- Query Optimizer

Doris can automatically optimize and process complex SQL requests through the query optimizer. The query optimizer deeply optimizes various complex SQL operators such as multi-table joins, aggregation, sorting, and pagination, fully utilizing cost models and relational algebra transformations to automatically obtain better or optimal logical and physical execution plans, greatly reducing the difficulty of writing SQL and improving usability and performance.

- Data Cache and IO Optimization

Access to external data sources is usually network access, which can have high latency and poor stability. Apache Doris provides rich caching mechanisms and has made numerous optimizations in cache types, timeliness, and strategies, fully utilizing memory and local high-speed disks to enhance the analysis performance of hot data. Additionally, Doris has made targeted optimizations for network IO characteristics such as high throughput, low IOPS, and high latency, providing external data source access performance comparable to local data.

- Materialized Views and Transparent Acceleration

Doris provides rich materialized view update strategies, supporting full and partition-level incremental refresh to reduce construction costs and improve timeliness. In addition to manual refresh, Doris also supports scheduled refresh and data-driven refresh, further reducing maintenance costs and improving data consistency. Materialized views also have transparent acceleration capabilities, allowing the query optimizer to automatically route to appropriate materialized views for seamless query acceleration. Additionally, Doris's materialized views use high-performance storage formats, providing efficient data access capabilities through column storage, compression, and intelligent indexing technologies, serving as an alternative to data caching and improving query efficiency.

As shown below, on a 1TB TPCDS standard test set based on the Iceberg table format, Doris's overall execution of 99 queries is only 1/3 of Trino's.

#### doris-tpcds

In actual user scenarios, Doris reduces average query latency by 20% and 95th percentile latency by 50% compared to Presto while using half the resources, significantly reducing resource costs while enhancing user experience.

doris-performance

## Convenient Service Migration

In the process of integrating multiple data sources and achieving lakehouse transformation, migrating SQL queries to Doris is a challenge due to differences in SQL dialects across systems in terms of syntax and function support. Without a suitable migration plan, the business side may need significant modifications to adapt to the new system's SQL syntax.

## Modern Deployment Architecture

Since version 3.0, Doris supports a cloud-native [compute-storage separation architecture](#). This architecture, with its low cost and high elasticity, effectively improves resource utilization and enables independent scaling of compute and storage.

#### compute-storage-decouple

The above diagram shows the system architecture of Doris's compute-storage separation, decoupling compute and storage. Compute nodes no longer store primary data, and the underlying shared storage layer (HDFS and object storage) serves as the unified primary data storage space, supporting independent scaling of compute and storage resources. The compute-storage separation architecture brings significant advantages to the lakehouse solution:

- **Low-Cost Storage:** Storage and compute resources can be independently scaled, allowing enterprises to increase storage capacity without increasing compute resources. Additionally, by using cloud object storage, enterprises can enjoy lower storage costs and higher availability, while still using local high-speed disks for caching relatively low-proportion hot data.
- **Single Source of Truth:** All data is stored in a unified storage layer, allowing the same data to be accessed and processed by different compute clusters, ensuring data consistency and integrity, and reducing the complexity of data synchronization and duplicate storage.
- **Workload Diversity:** Users can dynamically allocate compute resources based on different workload needs, supporting various application scenarios such as batch processing, real-time analysis, and machine learning. By separating storage and compute, enterprises can more flexibly optimize resource usage, ensuring efficient operation under different loads.

In addition, under the storage-computing coupled architecture, [elastic computing nodes](#) can still be used to provide elastic computing capabilities in lake warehouse data query scenarios.

## Openness

Doris not only supports access to open lake table formats but also has good openness for its own stored data. Doris provides an open storage API and [implements a high-speed data link based on the Arrow Flight SQL protocol](#), offering the speed advantages of Arrow Flight and the ease of use of JDBC/ODBC. Based on this interface, users can access data stored in Doris using Python/Java/Spark/Flink's ABDC clients.

Compared to open file formats, the open storage API abstracts the specific implementation of the underlying file format, allowing Doris to accelerate data access through advanced features in its storage format, such as rich indexing mechanisms. Additionally, upper-layer compute engines do not need to adapt to changes or new features in the underlying storage format, allowing all supported compute engines to simultaneously benefit from new features.

## Lakehouse Best Practices

In the lakehouse solution, Doris is mainly used for **lakehouse query acceleration**, **multi-source federated analysis**, and **lakehouse data processing**.

### Lakehouse Query Acceleration

In this scenario, Doris acts as a **compute engine**, accelerating query analysis on lakehouse data.

lakehouse query acceleration

### Cache Acceleration

For lakehouse systems like Hive and Iceberg, users can configure local disk caching. Local disk caching automatically stores query-designed data files in local cache directories and manages cache eviction using the

LRU strategy. For details, refer to the [Data Cache](#) document.

## Materialized Views and Transparent Rewrite

Doris supports creating materialized views for external data sources. Materialized views store pre-computed results as Doris internal table formats based on SQL definition statements. Additionally, Doris's query optimizer supports a transparent rewrite algorithm based on the SPJG (SELECT-PROJECT-JOIN-GROUP-BY) pattern. This algorithm can analyze the structure information of SQL, automatically find suitable materialized views for transparent rewrite, and select the optimal materialized view to respond to query SQL.

This feature can significantly improve query performance by reducing runtime computation. It also allows access to data in materialized views through transparent rewrite without business awareness. For details, refer to the [Materialized Views](#) document.

## Multi-Source Federated Analysis

Doris can act as a **unified SQL query engine**, connecting different data sources for federated analysis, solving data silos.

federated analysis

Users can dynamically create multiple catalogs in Doris to connect different data sources. They can use SQL statements to perform arbitrary join queries on data from different data sources. For details, refer to the [Catalog Overview](#).

## Lakehouse Data Processing

In this scenario, **Doris acts as a data processing engine**, processing lakehouse data.

lakehouse data processing

## Task Scheduling

Doris introduces the Job Scheduler feature, enabling efficient and flexible task scheduling, reducing dependency on external systems. Combined with data source connectors, users can achieve periodic processing and storage of external data. For details, refer to the [Job Scheduler](#).

## Data Modeling

User typically use data lakes to store raw data and perform layered data processing on this basis, making different layers of data available to different business needs. Doris's materialized view feature supports creating materialized views for external data sources and supports further processing based on materialized views, reducing system complexity and improving data processing efficiency.

## Data Write-Back

The data write-back feature forms a closed loop of Doris's lakehouse data processing capabilities. Users can directly create databases and tables in external data sources through Doris and write data. Currently, JDBC, Hive, and Iceberg data sources are supported, with more data sources to be added in the future. For details, refer to the documentation of the corresponding data source.

# Data Catalog Overview

A Data Catalog is used to describe the attributes of a data source.

In Doris, multiple catalogs can be created to point to different data sources (such as Hive, Iceberg, MySQL). Doris will automatically obtain the databases, tables, columns, partitions, data locations, etc. of the corresponding data sources through the catalogs. Users can access these catalogs for data analysis through standard SQL statements and can conduct join queries on the data from multiple catalogs.

There are two types of catalogs in Doris:

| Type             | Description                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Internal Catalog | The built-in catalog, named <code>internal</code> , used to store Doris internal table data. It cannot be created, modified, or deleted. |
| External Catalog | External catalogs refer to all catalogs other than the Internal Catalog. Users can create, modify, and delete external catalogs.         |

Catalogs are mainly applicable to the following three scenarios, but different catalogs are suitable for different scenarios. For details, see the documentation for the corresponding catalog.

| Scenario           | Description                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Query Acceleration | Direct query acceleration for data lakes such as Hive, Iceberg, Paimon, etc.                                                                   |
| Data Integration   | ZeroETL solution, directly accessing different data sources to generate result data, or facilitating data flow between different data sources. |
| Data Write-back    | After data processing via Doris, write back to external data sources.                                                                          |

This document uses [Iceberg Catalog](#) as an example to focus on the basic operations of catalogs. For detailed descriptions of different catalogs, please refer to the documentation of the corresponding catalog.

## Creating Catalog

Create an Iceberg Catalog using the `CREATE CATALOG` statement.

```
CREATE CATALOG iceberg_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hadoop',
 'warehouse' = 's3://bucket/dir/key',
 's3.endpoint' = 'https://s3.us-east-1.amazonaws.com',
 's3.access_key' = 'ak',
 's3.secret_key' = 'sk'
);
```

Essentially, a catalog created in Doris acts as a “proxy” to access the metadata services (such as Hive Metastore) and storage services (such as HDFS/S3) of the corresponding data source. Doris only stores connection properties and other information of the catalog, not the actual metadata and data of the corresponding data source.

## Common Properties

In addition to the set of properties specific to each catalog, here are the common properties for all catalogs {CommonProperties}.

| Property Name         | Description                                                                                                                                                                                                                                                                                                                                                               | Example                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| include_database_list | Supports synchronizing only specified Databases, separated by , . By default, all Databases are synchronized. Database names are case-sensitive. Use this parameter when there are many Databases in the external data source but only a few need to be accessed, to avoid synchronizing a large amount of metadata.                                                      | 'include_database_list' = 'db1,db2' |
| exclude_database_list | Supports specifying multiple Databases that do not need to be synchronized, separated by , . By default, no filtering is applied, and all Databases are synchronized. Database names are case-sensitive. This is used in the same scenario as above, to exclude databases that do not need to be accessed. If there is a conflict, exclude takes precedence over include. | 'exclude_database_list' = 'db1,db2' |

## Column Type Mapping

After a user creates a catalog, Doris automatically synchronizes the databases, tables, and columns of the catalog. For column type mapping rules of different catalogs, please refer to the documentation of the corresponding catalog.

For external data types that cannot currently be mapped to Doris column types, such as UNION, INTERVAL, etc., Doris will map the column type to UNSUPPORTED. For queries involving UNSUPPORTED types, see the example below:

Assume the synchronized table schema is:

```
k1 INT,
k2 INT,
k3 UNSUPPORTED,
k4 INT
```

The query behavior is as follows:

```
SELECT * FROM table; -- Error: Unsupported type 'UNSUPPORTED_TYPE' in 'k3'
SELECT * EXCEPT(k3) FROM table; -- Query OK.
SELECT k1, k3 FROM table; -- Error: Unsupported type 'UNSUPPORTED_TYPE' in 'k3'
SELECT k1, k4 FROM table; -- Query OK.
```

## Nullable Attribute

Doris currently has special restrictions on the Nullable attribute support for external table columns, with specific behaviors as follows:

| Source Type | Doris Read Behavior                                                     | Doris Write Behavior                                                                                                                 |
|-------------|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Nullable    | Nullable                                                                | Allow writing Null values                                                                                                            |
| Not Null    | Nullable, i.e., still treated as columns that allow NULL during reading | Allow writing Null values, i.e., no strict checking for Null values. Users need to ensure data integrity and consistency themselves. |

## Using Catalog

### Viewing Catalog

After creation, you can view the catalog using the `SHOW CATALOGS` command:

```
mysql> SHOW CATALOGS;
```

| CatalogId | CatalogName     | Type     | IsCurrent | CreateTime              | LastUpdateTime      | Comment                |
|-----------|-----------------|----------|-----------|-------------------------|---------------------|------------------------|
| 10024     | iceberg_catalog | iceberg  | yes       | 2023-12-25 16:11:41.687 | 2023-12-25 20:43:18 | NULL                   |
| 0         | internal        | internal |           | NULL                    | NULL                | Doris internal catalog |

You can view the statement to create a catalog using [SHOW CREATE CATALOG](#).

### Switching Catalog

Doris provides the `SWITCH` statement to switch the connection session context to the corresponding catalog. This is similar to using the `USE` statement to switch databases.

After switching to a catalog, you can use the `USE` statement to continue switching to a specified database, or use `SHOW DATABASES` to view the databases under the current catalog.

```
SWITCH iceberg_catalog;
```

```
SHOW DATABASES;
```

| Database           |
|--------------------|
| information_schema |
| mysql              |
| test               |
| iceberg_db         |

```
USE iceberg_db;
```

You can also use the `USE` statement with the fully qualified name `catalog_name.database_name` to switch directly to a specified database within a specified catalog:

```
USE iceberg_catalog.iceberg_db;
```

Fully qualified names can also be used in MySQL command line or JDBC connection strings to be compatible with the MySQL connection protocol.

```
Command line tool
mysql -h host -P9030 -uroot -Diceberg_catalog.iceberg_db

JDBC url
jdbc:mysql://host:9030/iceberg_catalog.iceberg_db
```

The fixed name for the built-in catalog is `internal`. The switching method is the same as for external catalogs.

## Default Catalog

The user attribute `default_init_catalog` is used to set the default catalog for a specific user. Once set, when the specified user connects to Doris, they will automatically switch to the set catalog.

```
SET PROPERTY default_init_catalog=hive_catalog;
```

Note 1: If the catalog has been explicitly specified in the MySQL command line or JDBC connection strings, then the specified catalog will be used, and the `default_init_catalog` user attribute will not take effect. Note 2: If the catalog set by the user attribute `default_init_catalog` no longer exists, it will automatically switch to the default `internal` catalog. Note 3: This feature takes effect starting from version v3.1.x.

## Simple Query

You can query tables in external catalogs using any SQL statement supported by Doris.

```
SELECT id, SUM(cost) FROM iceberg_db.table1
GROUP BY id ORDER BY id;
```

## Cross-Catalog Query

Doris supports join queries across different catalogs.

Here, let's create another MySQL Catalog:

```
CREATE CATALOG mysql_catalog properties(
 'type' = 'jdbc',
 'user' = 'root',
 'password' = '123456',
 'jdbc_url' = 'jdbc:mysql://host:3306/mysql_db',
 'driver_url' = 'mysql-connector-java-8.0.25.jar',
 'driver_class' = 'com.mysql.cj.jdbc.Driver'
);
```

Then, perform a join query between Iceberg tables and MySQL tables using SQL:

```
SELECT * FROM
iceberg_catalog.iceberg_db.table1 tbl1 JOIN mysql_catalog.mysql_db.dim_table tbl2
ON tbl1.id = tbl2.id;
```

## Data Import

You can import data from a data source into Doris using the INSERT command.

```
INSERT INTO internal.doris_db.tbl1
SELECT * FROM iceberg_catalog.iceberg_db.table1;
```

You can also use the CTAS (Create Table As Select) statement to create an internal Doris table from an external data source and import the data:

```
CREATE TABLE internal.doris_db.tbl1
PROPERTIES('replication_num' = '1')
AS
SELECT * FROM iceberg_catalog.iceberg_db.table1;
```

## Data Write-Back

Doris supports writing data back to external data sources using the INSERT statement. For more details, refer to:

- [Hive Catalog](#)
- [Iceberg Catalog](#)
- [JDBC Catalog](#)

## Refreshing Catalog

Catalogs created in Doris act as “proxy” to access the metadata services of corresponding data sources. Doris caches some metadata to improve access performance and reduce frequent cross-network requests. However, the cache has a validity period, and without refreshing, you cannot access the latest metadata. Therefore, Doris provides several ways to refresh catalogs.

```
-- Refresh catalog
REFRESH CATALOG catalog_name;

-- Refresh specified database
REFRESH DATABASE catalog_name.db_name;

-- Refresh specified table
REFRESH TABLE catalog_name.db_name.table_name;
```

Doris also supports disabling metadata caching to access the latest metadata in real-time.

For detailed information and configuration of metadata caching, please refer to: [Metadata Cache](#)

## Modifying Catalog

You can modify the properties or name of a catalog using the ALTER CATALOG statement:

```
-- Rename a catalog
ALTER CATALOG iceberg_catalog RENAME iceberg_catalog2;

-- Modify properties of a catalog
ALTER CATALOG iceberg_catalog SET PROPERTIES ('key1' = 'value1' [, 'key' = 'value2']);

-- Modify the comment of a catalog
ALTER CATALOG iceberg_catalog MODIFY COMMENT 'my iceberg catalog';
```

## Deleting Catalog

You can delete a specified external catalog using the DROP CATALOG statement.

```
DROP CATALOG [IF EXISTS] iceberg_catalog;
```

Deleting an external catalog from Doris does not remove the actual data; it only deletes the mapping relationship stored in Doris.

## Permission Management

The permission management for databases and tables in an external catalog is the same as for internal tables. For details, refer to the [Authentication and Authorization](#) documentation.

# Hive Catalog

By connecting to Hive Metastore or metadata services compatible with Hive Metastore, Doris can automatically retrieve Hive database and table information for data querying.

In addition to Hive, many other systems use Hive Metastore to store metadata. Therefore, through the Hive Catalog, we can access not only Hive tables but also other table formats that use Hive Metastore for metadata storage, such as Iceberg and Hudi.

**Writing to Hive through Doris is supported from version 2.1.3. Earlier 2.1.x releases only support querying.**

## Applicable Scenarios

| Scenario           | Description                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| Query Acceleration | Use Doris's distributed computing engine to directly access Hive data for query acceleration.                         |
| Data Integration   | Read Hive data and write it to Doris internal tables, or perform ZeroETL operations using the Doris computing engine. |
| Data Write-back    | Process data from any source supported by Doris and write it back to Hive tables.                                     |

## Configuring Catalog

### Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (
 'type'='hms', -- required
 'hive.metastore.type' = '<hive_metastore_type>', -- optional
 'hive.version' = '<hive_version>', -- optional
 'fs.defaultFS' = '<fs_defaultfs>', -- required for write, optional for read-only
 {MetaStoreProperties},
 {StorageProperties},
 {HiveProperties},
 {CommonProperties}
);
```

- <hive\_metastore\_type>

Specify the type of Hive Metastore.

- hms: Standard Hive Metastore service.
- glue: Access AWS Glue metadata service using Hive Metastore compatible interface.
- dlf: Access Alibaba Cloud DLF metadata service using Hive Metastore compatible interface.

- <fs\_defaultfs>

This parameter is required when writing data from Doris to tables in this Hive Catalog. Example:

```
'fs.defaultFS' = 'hdfs://namenode:port'
```

- {MetaStoreProperties}

The MetaStoreProperties section is for entering connection and authentication information for the Metastore metadata service. Refer to the “Supported Metadata Services” section for details.

- {StorageProperties}

The StorageProperties section is for entering connection and authentication information related to the storage system. Refer to the “Supported Storage Systems” section for details.

- {HiveProperties}

HiveProperties section is for entering properties related to Hive Catalog.

- `get_schema_from_table`: The default value is false. By default, Doris will obtain the table schema information from the Hive Metastore. However, in some cases, compatibility issues may occur, such as the error `Storage schema reading not supported`. In this case, you can set this parameter to true, and the table schema will be obtained directly from the Table object. But please note that this method will cause the default value information of the column to be ignored. This property is supported since version 2.1.10 and 3.0.6.
  - `hive.recursive_directories`: Whether to recurse into subdirectories when listing partition directories. This parameter has been supported since version 3.0.2. Before version 4.0, this parameter defaulted to false; in later versions, it defaults to true. The partition paths of some Hive tables may not match the partition information in the table schema. Setting this parameter to true is necessary to retrieve data files in subdirectories.
  - `hive.ignore_absent_partitions`: Whether to ignore non-existent partitions. Defaults to true. If set to false, the query will report an error when encountering non-existent partitions. This parameter has been supported since version 3.0.2.
- {CommonProperties}

The CommonProperties section is for entering common attributes. Please see the “Common Properties” section in the [Catalog Overview](#).

## Supported Hive Versions

Supports Hive 1.x, 2.x, 3.x, and 4.x.

Hive transactional tables are supported from version 3.x onwards. For details, refer to the “Hive Transactional Tables” section.

## Supported Metadata Services

- [Hive Metastore](#)
- [AWS Glue](#)
- [Aliyun DLF](#)

Note: The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

## Hive Catalog Feature Support Matrix

| Metadata Service | Table Query | View Query | DDL Operations | Data Writeback |
|------------------|-------------|------------|----------------|----------------|
| Hive             | ✓           | ✓          | ✓              | ✓              |
| AWS Glue         | ✓           | ✓          | ✗              | ✗              |
| DLF              | ✓           | ✓          | ✓              | ✓              |

## Supported Storage Systems

- [HDFS](#)
- [AWS S3](#)
- [Google Cloud Storage](#)
- [Azure Blob](#)
- [Alibaba Cloud OSS](#)
- [Tencent Cloud COS](#)
- [Huawei Cloud OBS](#)
- [MINIO](#)

To create Hive tables and write data through Doris, you need to explicitly add the `fs.defaultFS` property in the Catalog attributes. If the Catalog is created only for querying, this parameter can be omitted.

The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

## Supported Data Formats

- Hive
  - [Parquet](#)
  - [ORC](#)
  - [Text/CSV/JSON](#)
- Hudi
  - [Parquet](#)
  - [ORC](#)
- Iceberg

- [Parquet](#)
- [ORC](#)

## Column Type Mapping

| Hive Type     | Doris Type       | Comment                                                                                                                                                                                                                                       |
|---------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| boolean       | boolean          |                                                                                                                                                                                                                                               |
| tinyint       | tinyint          |                                                                                                                                                                                                                                               |
| smallint      | smallint         |                                                                                                                                                                                                                                               |
| int           | int              |                                                                                                                                                                                                                                               |
| bigint        | bigint           |                                                                                                                                                                                                                                               |
| date          | date             |                                                                                                                                                                                                                                               |
| timestamp     | datetime(6)      | Mapped to datetime with precision 6                                                                                                                                                                                                           |
| float         | float            |                                                                                                                                                                                                                                               |
| double        | double           |                                                                                                                                                                                                                                               |
| decimal(P, S) | decimal(P, S)    | Defaults to decimal(9, 0) if precision not specified                                                                                                                                                                                          |
| char(N)       | char(N)          |                                                                                                                                                                                                                                               |
| varchar(N)    | varchar(N)       |                                                                                                                                                                                                                                               |
| string        | string           |                                                                                                                                                                                                                                               |
| binary        | string/varbinary | Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is <code>false</code> , which maps to <code>string</code> ; when <code>true</code> , it maps to <code>varbinary</code> type. |
| array         | array            |                                                                                                                                                                                                                                               |
| map           | map              |                                                                                                                                                                                                                                               |
| struct        | struct           |                                                                                                                                                                                                                                               |
| other         | unsupported      |                                                                                                                                                                                                                                               |

## Examples

### Hive Metastore

Version 3.1+

### HDFS

```
Access HMS and HDFS services without Kerberos authentication
```sql
CREATE CATALOG hive_hms_hdfs_test_catalog PROPERTIES (
  'type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
  'fs.defaultFS' = 'hdfs://127.0.0.1:8520',
```

```

        'hadoop.username' = 'doris'
    );
    ...

Access HMS and HDFS services with Kerberos authentication enabled
```sql
CREATE CATALOG hive_hms_hdfs_kerberos_test_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
 'hive.metastore.client.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
 'hive.metastore.client.keytab' = '/keytabs/hive-presto-master.keytab',
 'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
 'hive.metastore.sasl.enabled' = 'true',
 'hive.metastore.authentication.type' = 'kerberos',
 'fs.defaultFS' = 'hdfs://127.0.0.1:8520',
 'hadoop.security.auth_to_local' = 'RULE:[2:$1@$0](.*@LABS.TERADATA.COM)s/@.*//
RULE:[2:$1@$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE:[2:$1@$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT',
 'hadoop.security.authentication' = 'kerberos',
 'hadoop.kerberos.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
 'hadoop.kerberos.keytab' = '/keytabs/hive-presto-master.keytab'
);
 ...

```

## ViewFs

```

```sql
CREATE CATALOG hive_viewfs PROPERTIES (
    'type' = 'hms',
    'hive.metastore.uris' = 'thrift://172.0.0.1:9083',
    'fs.defaultFS' = 'viewfs://your-cluster',
    'fs.viewfs.mounttable.your-cluster.link.ns1' = 'hdfs://your-nameservice/',
    'fs.viewfs.mounttable.your-cluster.homedir' = '/ns1',
    'dfs.nameservices' = 'your-nameservice',
    'dfs.ha.namenodes.your-nameservice' = 'nn1,nn2',
    'dfs.namenode.rpc-address.your-nameservice.nn1' = '172.21.0.2:8088',
    'dfs.namenode.rpc-address.your-nameservice.nn2' = '172.21.0.3:8088',
    'dfs.client.failover.proxy.provider.your-nameservice' =
'org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider'
);
    ...

```

S3

```

Access HMS without Kerberos authentication
```sql
CREATE CATALOG hive_hms_s3_test_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.region' = 'ap-east-1',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
 ...

Obtaining S3 access credentials using an IAM Assumed Role (3.1.2+)
```sql
CREATE CATALOG hive_hms_on_s3_iamrole PROPERTIES (
    'type' = 'hms',

```

```

'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
's3.region' = 'us-east-1',
's3.role_arn' = 'arn:aws:iam::543815668950:role/role'
);
...

```

OSS

Access HMS without Kerberos authentication

```

```sql
CREATE CATALOG hive_hms_on_oss_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'oss.region' = 'cn-beijing',

 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',

```

```

 'gs.access_key' = '<ak>',
 'gs.secret_key' = '<sk>',
 'fs.gcs.support'='true'
);
...

```

## Azure Blob

```

Supported since 3.1.3
```sql
CREATE CATALOG `hive_hms_on_azure_blob_new_catalog` PROPERTIES (
    'type' = 'hms',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'azure.account_name' = '<account_name>',
    'azure.account_key' = '<account_key>',
    'azure.endpoint' = 'https://<account_name>.blob.core.windows.net',
    'fs.azure.support'='true'
);
...

```

MinIO

```

```sql
CREATE CATALOG test_hive_on_hms_minio_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'fs.minio.support' = 'true',
 'minio.use_path_style' = 'true',
 'minio.endpoint' = 'http://127.0.0.1:19001',
 'minio.access_key' = '<ak>',
 'minio.secret_key' = '<sk>'
);
...

```

## Version 2.1 & 3.0

## HDFS

```

Access HMS without Kerberos authentication
```sql
CREATE CATALOG hive_hms_hdfs_test_catalog PROPERTIES (
    'type' = 'hms',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'hadoop.username' = 'doris',
    'fs.defaultFS' = 'hdfs://127.0.0.1:8320'
);
...

Access HMS with Kerberos authentication enabled
```sql
CREATE CATALOG test_two_hive_kerberos PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
 'hive.metastore.sasl.enabled' = 'true',

```

```

'hive.metastore.kerberos.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
'fs.defaultFS' = 'hdfs://127.0.0.1:8520',
'hadoop.kerberos.min.seconds.before.relogin' = '5',
'hadoop.security.authentication' = 'kerberos',
'hadoop.kerberos.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
'hadoop.kerberos.keytab' = '/keytabs/hive-presto-master.keytab',
'hadoop.security.auth_to_local' = 'RULE:[2:\$1@\$0](.*@LABS.TERADATA.COM)s/@.*//
RULE:[2:\$1@\$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE:[2:\$1@\$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT'
);
```

```

S3

```

```sql
CREATE CATALOG hms_on_s3_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```

```

OSS

```

```sql
CREATE CATALOG hive_hms_on_oss_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'oss.region' = 'cn-beijing',
 'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com',
 'oss.access_key' = '<ak>',
 'oss.secret_key' = '<sk>'
);
```

```

COS

```

```sql
CREATE CATALOG hive_hms_cos_test_region_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'cos.region' = 'ap-beijing',
 'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
 'cos.access_key' = '<ak>',
 'cos.secret_key' = '<sk>'
);
```

```

OBS

```
```sql
CREATE CATALOG test_hive_on_hms_obs_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'obs.region' = 'cn-north-4',
 'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
 'obs.access_key' = '<ak>',
 'obs.secret_key' = '<sk>'
);
```
```

GCS

```
```sql
CREATE CATALOG hive_hms_on_gcs_s3 PROPERTIES (
 'type'='hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'warehouse' = 's3://bucket/gcs/paimon_warehouse',
 'gs.access_key' = '<ak>',
 'gs.secret_key' = '<sk>',
 'gs.endpoint' = 'storage.googleapis.com'
);
```
```

MinIO

```
```sql
CREATE CATALOG test_hive_on_hms_minio_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.endpoint' = 'http://127.0.0.1:19000',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>',
 's3.path.style.access' = 'true'
);
```
```

AWS Glue

Version 3.1+

S3

AWS Glue and S3 storage services share the same authentication information.

```
```sql
CREATE CATALOG hive_glue_on_s3_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.type' = 'glue',
 'glue.region' = 'ap-east-1',
 'glue.endpoint' = 'https://glue.ap-east-1.amazonaws.com',
```

```

 'glue.access_key' = '<ak>',
 'glue.secret_key' = '<sk>'
);
 ...

```

When Glue service authentication information differs from S3 authentication information, you can specify S3 authentication information separately in the following way.

```

```sql
CREATE CATALOG hive_glue_on_s3_catalog PROPERTIES (
    'type' = 'hms',
    'hive.metastore.type' = 'glue',
    'glue.region' = 'ap-east-1',
    'glue.endpoint' = 'https://glue.ap-east-1.amazonaws.com',
    'glue.access_key' = '<ak>',
    'glue.secret_key' = '<sk>',
    's3.region' = 'ap-east-1',
    's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com/',
    's3.access_key' = '<ak>',
    's3.secret_key' = '<sk>'
);
...

```

Using IAM Assumed Role to obtain S3 access credentials (Since 3.1.2+)

```

```sql
CREATE CATALOG `glue_hive_iamrole` PROPERTIES (
 'type' = 'hms',
 'hive.metastore.type' = 'glue',
 'glue.region' = 'us-east-1',
 'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
 'glue.role_arn' = '<role_arn>'
);
...

```

## Version 2.1 & 3.0

### S3

AWS Glue and S3 storage services share the same authentication credentials.

In non-EC2 environments, you need to use [aws configure] (<https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-files.html>) to configure Credentials information and generate a credentials file in the ~/.aws directory.

Alternatively, you can explicitly specify the credentials provider factory class when creating the catalog:

```

"aws.catalog.credentials.provider.factory.class" =
"com.amazonaws.glue.catalog.credentials.ConfigurationAWSCredentialsProviderFactory"
```sql
create catalog hive_glue PROPERTIES(
    'type' = 'hms',
    'hive.metastore.type' = 'glue',
    'glue.endpoint' = 'https://glue.ap-northeast-1.amazonaws.com',
    'glue.region' = 'ap-northeast-1',
    'glue.access_key' = '<ak>',
    'glue.secret_key' = '<sk>'
);
...

```

Aliyun DLF

Version 3.1+

DLF 1.0

```
```sql
CREATE CATALOG hive_dlf_oss_test_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.type' = 'dlf',
 'dlf.uid' = '203225413946383283',
 'dlf.catalog_id' = 'p2_regression_case',
 'dlf.endpoint' = 'dlf.cn-beijing.aliyuncs.com',
 'dlf.region' = 'cn-beijing',
 'dlf.access_key' = '<ak>',
 'dlf.secret_key' = '<sk>'
);
```
```

Version 2.1 & 3.0

DLF 1.0

```
```sql
CREATE CATALOG hive_dlf_oss_test_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.type' = 'dlf',
 'dlf.uid' = '203225413946383283',
 'dlf.catalog.id' = 'p2_regression_case',
 'dlf.endpoint' = 'dlf.cn-beijing.aliyuncs.com',
 'dlf.region' = 'cn-beijing',
 'dlf.access_key' = '<ak>',
 'dlf.secret_key' = '<sk>'
);
```
```

Query Operations

Basic Query

After configuring the Catalog, you can query the table data within the Catalog using the following method:

```
-- 1. switch to catalog, use database and query
SWITCH hive_ctl;
USE hive_db;
SELECT * FROM hive_tbl LIMIT 10;

-- 2. use hive database directly
USE hive_ctl.hive_db;
SELECT * FROM hive_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM hive_ctl.hive_db.hive_tbl LIMIT 10;
```

Querying Hive Partitions

You can query Hive partition information using the following two methods:

- `SHOW PARTITIONS FROM [catalog.][db.]hive_table`

This statement lists all partitions and their values for the specified Hive table.

```
SHOW PARTITIONS FROM hive_table;
```

```
+-----+
| Partition |
+-----+
| pt1=2024-10-10/pt2=beijing |
| pt1=2024-10-10/pt2=shanghai |
| pt1=2024-10-11/pt2=beijing |
| pt1=2024-10-11/pt2=shanghai |
| pt1=2024-10-12/pt2=nanjing |
+-----+
```

- Using the `table$partitions` Metadata Table

Starting from versions 2.1.7 and 3.0.3, you can query Hive partition information through the `table$partitions` metadata table. This table is essentially relational, with each partition column represented as a column, allowing it to be used in any `SELECT` statement.

```
SELECT * FROM hive_table$partitions;
```

```
+-----+-----+
| pt1 | pt2 |
+-----+-----+
2024-10-10	beijing
2024-10-10	shanghai
2024-10-12	nanjing
2024-10-11	beijing
2024-10-11	shanghai
+-----+-----+
```

Querying Hive Transactional Tables

Hive Transactional tables support ACID semantics. For more details, see [Hive Transactions](#).

- Support for Hive Transactional Tables

| Table Type | Supported Operations in Hive | Hive Table Properties | Supported Hive Versions |
|---------------------------------|---------------------------------|---|---|
| Full-ACID Transactional Table | Supports Insert, Update, Delete | 'transactional'='true' | 4.x, 3.x, 2.x (2.x requires Major Compaction in Hive to read) |
| Insert-Only Transactional Table | Supports Insert only | 'transactional'='true',
'transactional_properties'='insert_only' | 4.x, 3.x, 2.x (specify <code>hive.version</code> when creating the catalog) |

- Current Limitations

Original Files scenarios are not supported. When a table is converted to a Transactional table, new data files will use the Hive Transactional table schema, but existing data files will not be converted. These files are referred to as Original Files.

Querying Hive Views

You can query Hive Views, but there are some limitations:

- The Hive View definition (HiveQL) must be compatible with SQL statements supported by Doris. Otherwise, a parsing error will occur.
- Some functions supported by HiveQL may have the same name as those in Doris but behave differently. This could lead to discrepancies between the results obtained from Hive and Doris. If you encounter such issues, please report them to the community.

Write Operations

Data can be written to Hive tables using the INSERT statement. This is supported for Hive tables created by Doris or existing Hive tables with compatible formats.

For partitioned tables, data will automatically be written to the corresponding partition or a new partition will be created based on the data. Currently, specifying a partition for writing is not supported.

INSERT INTO

The INSERT operation appends data to the target table. Specifying a partition for writing is currently not supported.

```
INSERT INTO hive_tbl VALUES (val1, val2, val3, val4);
INSERT INTO hive_ctl.hive_db.hive_tbl SELECT col1, col2 FROM internal.db1.tbl1;

INSERT INTO hive_tbl(col1, col2) VALUES (val1, val2);
INSERT INTO hive_tbl(col1, col2, partition_col1, partition_col2) VALUES (1, 2, "beijing", "2023-12-12");
```

INSERT OVERWRITE

INSERT OVERWRITE completely replaces the existing data in the table with new data. Specifying a partition for writing is currently not supported.

```
INSERT OVERWRITE TABLE hive_tbl VALUES (val1, val2, val3, val4);
INSERT OVERWRITE TABLE hive_ctl.hive_db.hive_tbl(col1, col2) SELECT col1, col2 FROM internal.db1.tbl1;
```

The semantics of INSERT OVERWRITE are consistent with Hive, with the following behaviors:

- If the target table is partitioned and the source table is empty, the operation has no effect. The target table remains unchanged.
- If the target table is non-partitioned and the source table is empty, the target table will be cleared.

- Since specifying a partition for writing is not supported, INSERT OVERWRITE automatically handles the relevant partitions in the target table based on the source table values. If the target table is partitioned, only the affected partitions will be overwritten; unaffected partitions remain unchanged.

CTAS

You can create a Hive table and insert data using the CTAS (CREATE TABLE AS SELECT) statement:

```
CREATE TABLE hive_ctas ENGINE=hive AS SELECT * FROM other_table;
```

CTAS supports specifying file formats, partitioning methods, and more, as shown below:

```
CREATE TABLE hive_ctas ENGINE=hive
PARTITION BY LIST (pt1, pt2) ()
AS SELECT col1, pt1, pt2 FROM part_ctas_src WHERE col1 > 0;

CREATE TABLE hive_ctl.hive_db.hive_ctas (col1, col2, pt1) ENGINE=hive
PARTITION BY LIST (pt1) ()
PROPERTIES (
    "file_format"="parquet",
    "compression"="zstd"
)
AS SELECT col1, pt1 AS col2, pt2 AS pt1 FROM test_ctas.part_ctas_src WHERE col1 > 0;
```

Related Parameters

- Session variables

| Parameter name | Default value | Description | Since version |
|-------------------------------|---------------|---|----------------|
| hive_parquet_use_column_names | true | When Doris reads the Parquet data type of the Hive table, it will find the column with the same name from the Parquet file to read the data according to the column name of the Hive table by default. When this variable is false, Doris will read data from the Parquet file according to the column order in the Hive table, regardless of the column name. Similar to the <code>parquet.column.index.access</code> variable in Hive. This parameter only applies to the top-level column name and is invalid inside the Struct. | 2.1.6+, 3.0.3+ |

| Parameter name | Default value | Description | Since version |
|---------------------------|---------------|---|----------------|
| hive_orc_use_column_names | true | Similar to hive_parquet_use_column_names, it is for the Hive table ORC data type. Similar to the orc.force.positional_evolution variable in Hive. | 2.1.6+, 3.0.3+ |

- BE

| Parameter Name | Default Value | Description |
|-------------------------|---------------|--|
| hive_sink_max_file_size | 1GB | Maximum data file size.
When the data size exceeds this limit, the current file will be closed, and a new file will be created for further writing. |

| Parameter Name | Default Value | Description |
|--|---------------|--|
| table_sink_partition_write_max_partition_nums_per_writer | 128 | Maximum number of partitions that each instance can write to on a BE node. |

| Parameter Name | Default Value | Description |
|---|---------------|--|
| table_sink_non_partition_write_scaling_data_processed_threshold | 25MB | Data volume threshold for starting scaling-write for non-partitioned tables. A new writer (instance) will be used for every additional table_sink_non_partition_write_scaling_ |

| Parameter Name | Default Value | Description |
|----------------|---------------|--|
| | | data processed threshold of data. This mechanism adjusts the number of writers (instances) based on data volume to enhance concurrent write throughput, saving resources |

| Parameter Name | Default Value | Description |
|----------------|---------------|---|
| | | ces and minimizing file numbers for smaller data volumes. |

| Parameter Name | Default Value | Description |
|---|---------------|---|
| table_sink_partition_write_min_data_processed_rebalance_threshold | 25MB | Minimum data volume threshold to trigger rebalancing for partitioned tables. Rebalancing is triggered if current accumulated data volume - data volume since last reb |

| Parameter Name | Default Value | Description |
|----------------|---------------|---|
| | | balancing or initial accumulation $\geq$ table_sink_partition_write_min_data_processed_rebalance_threshold. If the final file size varies significantly, reduce this threshold to improve |

| Parameter Name | Default Value | Description |
|----------------|---------------|--|
| | | balance. However, a lower threshold may increase rebalancing costs, potentially affecting performance. |

| Parameter Name | Default Value | Description |
|---|---------------|--|
| table_sink_partition_write_min_partition_data_processed_rebalance_threshold | 15MB | Minimum partition data volume threshold to trigger rebalancing. Rebalancing occurs if current partition data volume $\geq$ threshold * number of tasks already allocated |

| Parameter Name | Default Value | Description |
|----------------|---------------|---|
| | | to the partition. If the final file size varies significantly, reduce this threshold to improve balance. However, a lower threshold may increase rebalancing costs, potentially affecting |

| Parameter Name | Default Value | Description |
|----------------|---------------|----------------|
| | | g performance. |

Database and Table Management

Users can create and delete databases and tables in the Hive Metastore through Doris. Note that Doris only calls the Hive Metastore API for these operations and does not store or persist any Hive metadata itself.

Creating and Dropping Databases

You can switch to the appropriate Catalog using the SWITCH statement and execute the CREATE DATABASE statement:

```
SWITCH hive_ctl;
CREATE DATABASE [IF NOT EXISTS] hive_db;
```

You can also create a database using a fully qualified name or specify a location, such as:

```
CREATE DATABASE [IF NOT EXISTS] hive_ctl.hive_db;

CREATE DATABASE [IF NOT EXISTS] hive_ctl.hive_db
PROPERTIES ('location'='hdfs://172.21.16.47:4007/path/to/db/');
```

You can view the location information of the Database using the SHOW CREATE DATABASE command:

```
mysql> SHOW CREATE DATABASE hive_db;
+-----+-----+
| Database | Create Database |
+-----+-----+
| hive_db | CREATE DATABASE hive_db LOCATION 'hdfs://172.21.16.47:4007/usr/hive/warehouse/hive_db.db' |
+-----+-----+
```

To drop a database:

```
DROP DATABASE [IF EXISTS] hive_ctl.hive_db;
```

For a Hive Database, you must first delete all tables under that Database before you can delete the Database itself; otherwise, an error will occur. This operation will also delete the corresponding Database in Hive.

Creating and Dropping Tables

- **Creating Tables**

Doris supports creating both partitioned and non-partitioned tables in Hive.

```
-- Create unpartitioned hive table
CREATE TABLE unpartitioned_table (
  `col1` BOOLEAN COMMENT 'col1',
  `col2` INT COMMENT 'col2',
  `col3` BIGINT COMMENT 'col3',
  `col4` CHAR(10) COMMENT 'col4',
  `col5` FLOAT COMMENT 'col5',
  `col6` DOUBLE COMMENT 'col6',
  `col7` DECIMAL(9,4) COMMENT 'col7',
  `col8` VARCHAR(11) COMMENT 'col8',
  `col9` STRING COMMENT 'col9'
) ENGINE=hive
PROPERTIES (
  'file_format'='parquet'
);

-- Create partitioned hive table
-- The partition columns must be in table's column definition list
CREATE TABLE partition_table (
  `col1` BOOLEAN COMMENT 'col1',
  `col2` INT COMMENT 'col2',
  `col3` BIGINT COMMENT 'col3',
  `col4` DECIMAL(2,1) COMMENT 'col4',
  `pt1` VARCHAR COMMENT 'pt1',
  `pt2` VARCHAR COMMENT 'pt2'
) ENGINE=hive
PARTITION BY LIST (pt1, pt2) ()
PROPERTIES (
  'file_format'='orc',
  'compression'='zlib'
);

-- Create text format table(Since 2.1.7 & 3.0.3)
CREATE TABLE text_table (
  `id` INT,
  `name` STRING
) PROPERTIES (
  'file_format'='text',
  'compression'='gzip',
  'field.delim'='\t',
  'line.delim'='\n',
  'collection.delim'=';',
  'mapkey.delim'=':',
  'serialization.null.format'='\N',
  'escape.delim' '\\'
);
```

After creating a table, you can view the Hive table creation statement using the `SHOW CREATE TABLE` command.

Note that unlike Hive's table creation syntax, when creating a partitioned table in Doris, partition columns must be included in the table schema. Additionally, partition columns must be placed at the end of the schema and maintain the same order.

For Hive clusters where ACID transaction features are enabled by default, tables created by Doris will have the `transactional` property set to `true`. Since Doris only supports certain features of Hive transactional tables, this may lead to issues where Doris cannot read the Hive tables it creates. To avoid this, explicitly set `"transactional" = "false"` in the table properties to create non-transactional Hive tables:

```
CREATE TABLE non_acid_table(
  `col1` BOOLEAN COMMENT 'col1',
  `col2` INT COMMENT 'col2',
  `col3` BIGINT COMMENT 'col3'
) ENGINE=hive
PROPERTIES (
  'transactional'='false'
);
```

- **Dropping Tables**

You can delete a Hive table using the `DROP TABLE` statement. When a table is deleted, all data, including partition data, is also removed.

- **Column Type Mapping**

Refer to the [Column Type Mapping](#) section for details. Note the following restrictions:

- Columns must be of the default nullable type; `NOT NULL` is not supported.
- Hive 3.0 supports setting default values. To set default values, explicitly add `"hive.version" = "3.0.0"` in the catalog properties.
- If inserted data types are incompatible (e.g., inserting `'abc'` into a numeric type), the value will be converted to `null`.

- **Partitioning**

In Hive, partition types correspond to List partitions in Doris. Therefore, when creating a Hive partitioned table in Doris, use the List partition syntax, but there is no need to explicitly enumerate each partition. Doris will automatically create the corresponding Hive partition based on data values during data insertion. Single-column or multi-column partitioned tables are supported.

- **File Formats**

- ORC (default)
- Parquet

Note that when the `DATETIME` type is written to a Parquet file, the physical type used is `INT96` instead of `INT64`. This is to be compatible with the logic of Hive versions prior to 4.0.

- Text (supported from versions 2.1.7 and 3.0.3)

Text format supports the following table properties:

```
- `field.delim`: Column delimiter. Default is `\\1`.
- `line.delim`: Line delimiter. Default is `\\n`.
- `collection.delim`: Delimiter for elements in complex types. Default is `\\2`.
- `mapkey.delim`: Delimiter for map key-value pairs. Default is `\\3`.
```

- ``serialization.null.format``: Format for storing ``NULL`` values. Default is ``\N``.
- ``escape.delim``: Escape character. Default is ``\``.

- **Compression Formats**

- Parquet: snappy (default), zstd, plain (no compression)
- ORC: snappy, zlib (default), zstd, plain (no compression)
- Text: gzip, deflate, bzip2, zstd, lz4, lzo, snappy, plain (default, no compression)

- **Storage Medium**

- HDFS
- Object Storage

Subscribing to Hive Metastore Events

By having the FE nodes periodically read Notification Events from the HMS, Doris can detect real-time changes in Hive table metadata, improving metadata timeliness. Currently, the following events are supported:

| Event | Action and Corresponding Behavior |
|-----------------|---|
| CREATE DATABASE | Creates a database in the corresponding data directory. |
| DROP DATABASE | Deletes a database in the corresponding data directory. |
| ALTER DATABASE | Mainly affects changes to database properties, comments, and default storage locations. These changes do not affect Doris's ability to query external data directories, so this event is currently ignored. |
| CREATE TABLE | Creates a table in the corresponding database. |
| DROP TABLE | Deletes a table in the corresponding database and invalidates the table cache. |
| ALTER TABLE | If renamed, deletes the old table and creates a new one with the new name; otherwise, invalidates the table cache. |
| ADD PARTITION | Adds a partition to the cached partition list of the corresponding table. |
| DROP PARTITION | Removes a partition from the cached partition list and invalidates the partition cache. |
| ALTER PARTITION | If renamed, deletes the old partition and creates a new one with the new name; otherwise, invalidates the partition cache. |

1. When data import causes file changes, partitioned tables trigger an ALTER PARTITION event, while non-partitioned tables trigger an ALTER TABLE event.

2. If you bypass HMS and directly manipulate the file system, HMS will not generate corresponding events, and Doris will not detect metadata changes.

The following parameters in `fe.conf` are related to this feature:

1. `enable_hms_events_incremental_sync`: Enables automatic incremental metadata synchronization. Disabled by default.
2. `hms_events_polling_interval_ms`: Interval for reading events, default is 10000 milliseconds.

3. `hms_events_batch_size_per_rpc`: Maximum number of events to read per RPC, default is 500.

To use this feature (excluding Huawei Cloud MRS), you need to modify the `hive-site.xml` of HMS and restart both HMS and HiveServer2.

```
<property>
  <name>hive.metastore.event.db.notification.api.auth</name>
  <value>false</value>
</property>
<property>
  <name>hive.metastore.dml.events</name>
  <value>true</value>
</property>
<property>
  <name>hive.metastore.transactional.event.listeners</name>
  <value>org.apache.hive.hcatalog.listener.DbNotificationListener</value>
</property>
```

For Huawei Cloud MRS, you need to modify the `hivemetastore-site.xml` and restart both HMS and HiveServer2.

```
<property>
  <name>metastore.transactional.event.listeners</name>
  <value>org.apache.hive.hcatalog.listener.DbNotificationListener</value>
</property>
```

Appendix

Transaction Mechanism

Write operations to Hive are placed in a separate transaction. Before the transaction is committed, the data is not visible externally. Only after the transaction is committed do the related table operations become visible to others.

Transactions ensure the atomicity of operations, meaning all operations within a transaction either succeed together or fail together.

Transactions cannot fully guarantee isolation of operations, but they strive to minimize inconsistencies by separating file system operations from Hive Metastore metadata operations.

For example, in a transaction that requires modifying multiple partitions of a Hive table, if the task is divided into two batches, the first batch might be visible externally before the second batch is completed. This means the first batch of partitions can be read, but the second batch cannot.

If any exceptions occur during the transaction commit process, the transaction will be rolled back completely, including modifications to HDFS files and Hive Metastore metadata, without requiring any additional user intervention.

Concurrent Writing Mechanism

Apache Doris currently supports concurrent writing using multiple insert statements. However, users need to ensure that concurrent writes do not result in potential conflicts.

Since regular non-transactional Hive tables lack a complete transaction mechanism, the Apache Doris transaction mechanism aims to minimize inconsistency windows but cannot guarantee true ACID properties. Therefore, concurrent writes to Hive tables in Apache Doris may lead to data consistency issues.

1. **Concurrent INSERT Operations**

2. INSERT operations append data and do not conflict when executed concurrently, producing the expected results.

3. **Concurrent INSERT OVERWRITE Operations**

4. Concurrent INSERT OVERWRITE operations on the same table or partition may lead to data loss or corruption, resulting in unpredictable outcomes.

5. Common solutions include:

- For partitioned tables, write data to different partitions. Concurrent operations on different partitions do not conflict.
- For non-partitioned tables, use INSERT instead of INSERT OVERWRITE to avoid conflicts.
- For operations that may conflict, ensure that only one write operation occurs at a time on the business side.

HDFS File Operations

For Hive table data on HDFS, data is typically first written to a temporary directory, then finalized using file system operations like rename. Below is a detailed explanation of the specific file operations on HDFS for different data operations.

The temporary directory format for data is: `/tmp/.doris_staging/<username>/<uuid>`

The format for the written data file names is: `<query-id>_<uuid>-<index>.<compress-type>.<file-type>`

Here are examples of file operations under various scenarios:

1. **Non-Partitioned Table**

◦ **Append (Add Data)**

- Target table directory: `hdfs://ns/usr/hive/warehouse/example.db/table1`
- Temporary file:
`hdfs://ns/tmp/.doris_staging/root/f02247cb662846038baae272af5eeb05/b35fdbcea3a4e39-86d1f36987ef1492_7e3985bf-9de9-4fc7-b84e-adf11aa08756-0.orc`
- During the commit phase, all temporary files are moved to the target table directory.

◦ **Overwrite (Replace Data)**

- Target table directory: `hdfs://ns/usr/hive/warehouse/example.db/table1`
- Temporary file:
`hdfs://ns/tmp/.doris_staging/root/f02247cb662846038baae272af5eeb05/b35fdbc`

ea3a4e39-86d1f36987ef1492_7e3985bf-9de9-4fc7-b84e-adf11aa08756-0.orc

- Commit phase steps:

1. Rename the target table directory to a temporary directory:
`hdfs://ns/usr/hive/warehouse/example.db/_temp_b35fdbcea3a4e39-86d1f36987ef1492_table1`
2. Rename the temporary directory to the target table directory.
3. Delete the temporary target table directory.

2. Partitioned Table

- **Add (Add to New Partition)**

- Target table directory:
`hdfs://ns/usr/hive/warehouse/example.db/table2/part_col=2024-01-01`
- Temporary file:
`hdfs://ns/tmp/.doris_staging/root/a7eac7505d7a42fdb06cb9ef1ea3e912/par1=a/d678a74d232345e0-b659e2fb58e86ffd_549ad677-ee75-4fa1-b8a6-3e821e1dae61-0.orc`
- During the commit phase, the temporary directory is renamed to the target table directory.

- **Append (Add Data to Existing Partition)**

- Target table directory:
`hdfs://ns/usr/hive/warehouse/example.db/table2/part_col=2024-01-01`
- Temporary file:
`hdfs://ns/tmp/.doris_staging/root/a7eac7505d7a42fdb06cb9ef1ea3e912/par1=a/d678a74d232345e0-b659e2fb58e86ffd_549ad677-ee75-4fa1-b8a6-3e821e1dae61-0.orc`
- During the commit phase, files from the temporary directory are moved to the target table directory.

- **Overwrite (Replace Existing Partition)**

- Target table directory:
`hdfs://ns/usr/hive/warehouse/example.db/table2/part_col=2024-01-01`
- Temporary file:
`hdfs://ns/tmp/.doris_staging/root/a7eac7505d7a42fdb06cb9ef1ea3e912/par1=a/d678a74d232345e0-b659e2fb58e86ffd_549ad677-ee75-4fa1-b8a6-3e821e1dae61-0.orc`
- Commit phase steps:
 1. Rename the target partition directory to a temporary partition directory:
`hdfs://ns/usr/hive/warehouse/example.db/table2/_temp_d678a74d232345e`

0-b659e2fb58e86ffd_part_col=2024-01-01

2. Rename the temporary partition directory to the target partition directory.
3. Delete the temporary target partition directory.

Change Log

Doris Version	Feature Support
2.1.6	Support for writing back to Hive tables
3.0.4	Support for Hive tables in JsonSerDe format. Support for transactional tables in Hive4.

Iceberg Catalog

Doris supports accessing Iceberg table data through various metadata services. In addition to reading data, Doris also supports writing to Iceberg tables.

[Quick start with Apache Doris and Apache Iceberg.](#)

Users can access Iceberg tables using Hive Metastore as metadata through the Hive Catalog. However, it is still recommended to use the Iceberg Catalog directly to avoid some compatibility issues.

Applicable Scenarios

Scenario	Description
Query Acceleration	Use Doris's distributed computing engine to directly access Iceberg data for faster queries.
Data Integration	Read Iceberg data and write it to internal Doris tables, or perform ZeroETL operations using the Doris computing engine.
Data Write-back	Process data from any Doris-supported data source and write it back to Iceberg table storage.

Configuring Catalog

Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (  
  'type' = 'iceberg',  
  'iceberg.catalog.type' = '<iceberg_catalog_type>',  
  'warehouse' = '<warehouse>', --optional  
  {MetaStoreProperties},  
  {StorageProperties},  
  {IcebergProperties},  
  {CommonProperties}  
);
```

- <iceberg_catalog_type>

The type of Iceberg Catalog, supporting the following options:

- hms: Uses Hive Metastore as the metadata service.
- rest: Metadata service compatible with the Iceberg Rest Catalog interface.
- hadoop: Directly accesses metadata stored on the file system.
- glue: Uses AWS Glue as the metadata service.

- `d1f`: Uses Alibaba Cloud DLF as the metadata service.
- `s3tables`: Uses AWS S3 Tables Catalog to visit [S3 Table Bucket](#).

- `<warehouse>`

The warehouse path for Iceberg. This parameter must be specified when `<iceberg_catalog_type>` is `hadoop`.

The warehouse path must point to the level above the Database path. For example, if your table path is `s3://bucket/path/to/db1/table1`, then the warehouse should be `s3://bucket/path/to/`.

- `{MetaStoreProperties}`

The `MetaStoreProperties` section is for entering connection and authentication information for the Metastore metadata service. Refer to the section on [Supported Metadata Services](#).

- `{StorageProperties}`

The `StorageProperties` section is for entering connection and authentication information related to the storage system. Refer to the section on [Supported Storage Systems](#).

- `{IcebergProperties}`

The `IcebergProperties` section is used to fill in parameters specific to Iceberg Catalog.

- `list-all-tables`

For Iceberg Catalog that uses Hive Metastore as the metadata service. Default is `true`. By default, the `SHOW TABLES` operation will list all types of tables in the current Database (Hive Metastore may store non-Iceberg type tables). This approach has the best performance.

If set to `false`, Doris will check the type of each table one by one and only return Iceberg type tables. This mode will have poor performance when there are many tables.

- `{CommonProperties}`

The `CommonProperties` section is for entering general properties. See the [Catalog Overview](#) for details on common properties.

Supported Iceberg Versions

Doris Version	Iceberg SDK Version
2.1	1.6.1
3.0	1.6.1
3.1	1.9.1
4.0	1.9.1

Supported Iceberg Formats

- Supports Iceberg V1/V2 formats.

- Supports reading Position Delete and Equality Delete.
- Supports reading Deletion Vector (Since 4.1.0).

Supported Metadata Services

- [Hive Metastore](#)
- [AWS Glue](#)
- [Aliyun DLF](#)
- [Iceberg Rest Catalog](#)
- [FileSystem](#)

Note: The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

Iceberg Catalog Feature Support Matrix

Metadata Service	Table Query	View Query	DDL Operations	Data Writeback	System Tables (Supported since 3.1+)
Hive MetaStore	✓	✓	✓	✓	✓
AWS Glue	✓	✓	✗	✗	✓
Aliyun DLF	✓	✓	✗	✗	✗
Iceberg Rest Catalog	✓	✓	Depends on the service provider	Depends on the service provider	Depends on the service provider
FileSystem	✓	✓	✓	✓	✓

Supported Storage Systems

- [HDFS](#)
- [AWS S3](#)
- [Google Cloud Storage](#)
- [Azure Blob](#)
- [Aliyun OSS](#)
- [Tencent COS](#)
- [Huawei OBS](#)
- [MINIO](#)

Note: The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

Supported Data Formats

- [Parquet](#)

- [ORC](#)

Column Type Mapping

Iceberg Type	Doris Type	Comment
boolean	boolean	
integer	int	
long	bigint	
float	float	
double	double	
decimal(P, S)	decimal(P, S)	
date	date	
timestamp (Timestamp without timezone)	datetime(6)	Mapped to datetime with precision 6
timestamptz (Timestamp with timezone)	datetime(6)	Mapped to datetime with precision 6
fixed(N)	char(N)	
string	string	
binary	string/varbinary	Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is <code>false</code> , which maps to <code>string</code> ; when <code>true</code> , it maps to <code>varbinary</code> type.
uuid	string/varbinary	version < 4.0.2 maps to <code>string</code> type; version == 4.0.2 maps to <code>varbinary</code> type. For version > 4.0.2, it is controlled by the <code>enable.mapping.varbinary</code> property in the properties. The default is <code>false</code> , which maps to <code>string</code> .
struct	struct (supported from version 2.1.3)	
map	map (supported from version 2.1.3)	
list	array	
other	UNSUPPORTED	

Note:

Doris currently does not support Timestamp types with timezone. All `timestamp` and `timestamptz` will be uniformly mapped to `datetime(N)` type. However, during reading and writing, Doris will correctly handle timezones based on the actual source type. For example, after specifying a timezone with `SET time_zone=<tz>`, it will affect the reading and writing results of `timestamptz` columns.

You can check whether the source type has timezone information in the Extra column of the DESCRIBE table_name statement. If it shows WITH_TIMEZONE, it indicates that the source type is a timezone-aware type. (Supported since 3.1.0).

Namespace Mapping

Iceberg’s metadata hierarchy is Catalog -> Namespace -> Table. Namespace can have multiple levels (Nested Namespace).

Starting from version 3.1.2, for Iceberg Rest Catalog, Doris supports mapping of Nested Namespace.

In the above example, tables will be mapped to Doris metadata according to the following logic:

Catalog	Database	Table
Catalog	NS1	Table1
Catalog	NS2.NS3	Table2
Catalog	NS2.NS3	Table3

Support for Nested Namespace needs to be explicitly enabled. For details, please refer to [Iceberg Rest Catalog](#)

Examples

Hive Metastore

3.1+ Version

HDFS

```
Access HMS and HDFS services without Kerberos authentication
```sql
CREATE CATALOG iceberg_hms_on_hdfs_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
```

```

 'warehouse' = 'hdfs://127.0.0.1:8320/user/iceberg/warehouse/iceberg-hms-hdfs-warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'fs.defaultFS' = 'hdfs://127.0.0.1:8320',
 'hadoop.username' = 'doris'
);
 ...

Access HMS and HDFS services with Kerberos authentication enabled
```sql
CREATE CATALOG iceberg_hms_on_hdfs_kerberos_hdfs_catalog PROPERTIES (
    'type' = 'iceberg',
    'iceberg.catalog.type' = 'hms',
    'warehouse' = 'hdfs://127.0.0.1:8520/iceberg-hms-hdfs-warehouse',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
    'hive.metastore.client.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
    'hive.metastore.client.keytab' = '/keytabs/hive-presto-master.keytab',
    'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
    'hive.metastore.sasl.enabled' = 'true',
    'hive.metastore.authentication.type' = 'kerberos',
    'hadoop.security.auth_to_local' = 'RULE:[2:$1@$0](.*@LABS.TERADATA.COM)s/@.*//
RULE:[2:$1@$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE:[2:$1@$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT',
    'fs.defaultFS' = 'hdfs://127.0.0.1:8520',
    'hadoop.security.authentication' = 'kerberos',
    'hadoop.kerberos.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
    'hadoop.kerberos.keytab' = '/keytabs/hive-presto-master.keytab'
);
    ...

```

S3

```

Access HMS without Kerberos authentication
```sql
CREATE CATALOG iceberg_hms_on_s3_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'warehouse' = 's3://selectdb-qa-datalake-test-hk/refactor-test/iceberg-hms-s3-warehouse',
 's3.region' = 'ap-east-1',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
 ...

Obtaining S3 access credentials using an IAM Assumed Role (3.1.2+)
```sql
CREATE CATALOG iceberg_hms_on_s3_iamrole PROPERTIES (
    'type' = 'iceberg',
    'iceberg.catalog.type' = 'hms',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'warehouse' = 's3://bucket/warehouse',
    's3.region' = 'us-east-1',
    's3.role_arn' = 'arn:aws:iam::543815668950:role/role'
);
    ...

```

OSS

Access HMS without Kerberos authentication

```
```sql
```

```
CREATE CATALOG iceberg_hms_on_oss_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'oss://bucket/iceberg/iceberg-hms-warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9083',
 'oss.region' = 'cn-beijing',
 'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com',
 'oss.access_key' = '<ak>',
 'oss.secret_key' = '<sk>'
```

```
);
```
```

Access HMS with Kerberos authentication enabled

```
```sql
```

```
CREATE CATALOG iceberg_hms_on_oss_kerberos_new_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'oss://bucket/iceberg/iceberg-hms-warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
 'hive.metastore.client.principal' = 'presto-server/presto-
master.docker.cluster@LABS.TERADATA.COM',
 'hive.metastore.client.keytab' = '/keytabs/presto-server.keytab',
 'hive.metastore.authentication.type' = 'kerberos',
 'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
 'hive.metastore.sasl.enabled' = 'true',
 'hadoop.security.auth_to_local' = 'RULE: [2:$1@$0](.*@LABS.TERADATA.COM)s/@.*//
RULE: [2:$1@$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE: [2:$1@$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT',
 'oss.region' = 'cn-beijing',
 'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com',
 'oss.access_key' = '<ak>',
 'oss.secret_key' = '<sk>'
```

```
);
```
```

COS

Access HMS without Kerberos authentication

```
```sql
```

```
CREATE CATALOG `iceberg_hms_on_cos_catalog` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'cos://bucket/iceberg-hms-cos-warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'cos.region' = 'ap-beijing',
 'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
 'cos.secret_key' = '<sk>',
 'cos.access_key' = '<ak>'
```

```
);
```
```

Access HMS with Kerberos authentication enabled

```
```sql
```

```
CREATE CATALOG `iceberg_hms_on_cos_kerberos_new_catalog` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'cos://bucket/iceberg-hms-cos-warehouse',
```

```

'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
'hive.metastore.sasl.enabled' = 'true',
'hive.metastore.client.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
'hive.metastore.client.keytab' = '/keytabs/hive-presto-master.keytab',
'hadoop.security.auth_to_local' = 'RULE: [2:$1@$0](.*@LABS.TERADATA.COM)s/@.*//
RULE: [2:$1@$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE: [2:$1@$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT',
'cos.region' = 'ap-beijing',
'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
'cos.secret_key' = '<sk>',
'cos.access_key' = '<ak>'
);
...

```

## OBS

```

Access HMS without Kerberos authentication
```sql
CREATE CATALOG test_iceberg_on_hms_obs_catalog PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'hms',
  'warehouse' = 'obs://bucket/regression/iceberg',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
  'obs.region' = 'cn-north-4',
  'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
  'obs.access_key' = '<ak>',
  'obs.secret_key' = '<sk>'
);
...

Access HMS with Kerberos authentication enabled
```sql
CREATE CATALOG obs PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'obs://bucket/regression/iceberg1',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
 'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
 'hive.metastore.sasl.enabled' = 'true',
 'hive.metastore.client.principal' = 'hive/presto-master.docker.cluster@LABS.TERADATA.COM',
 'hive.metastore.client.keytab' = '/keytabs/hive-presto-master.keytab',
 'hive.metastore.authentication.type' = 'kerberos',
 'hadoop.security.auth_to_local' = 'RULE: [2:\$1@\$0](.*@LABS.TERADATA.COM)s/@.*//
RULE: [2:\$1@\$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
RULE: [2:\$1@\$0](.*@OTHERREALM.COM)s/@.*//
DEFAULT',
 'obs.region' = 'cn-north-4',
 'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
 'obs.access_key' = '<ak>',
 'obs.secret_key' = '<sk>'
);
...

```

## GCS

```

```sql
CREATE CATALOG `iceberg_hms_on_gcs_kerberos_new_catalog` PROPERTIES (

```

```

        'type' = 'iceberg',
        'iceberg.catalog.type' = 'hms',
        'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
        'warehouse' = 'gs://bucket/iceberg_warehouse',
        'gs.access_key' = '<ak>',
        'gs.secret_key' = '<sk>',
        'fs.gcs.support'='true'
    );
    ...

```

Azure Blob

```

Supported since 3.1.3
```sql
CREATE CATALOG iceberg_fs_on_azure_blob_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hadoop',
 'warehouse' = 'abfs://<container>@<account_name>.dfs.core.windows.net/iceberg-warehouse',
 'azure.account_name' = '<account_name>',
 'azure.account_key' = '<account_key>',
 'azure.endpoint' = 'https://<account_name>.blob.core.windows.net',
 'fs.azure.support'='true'
);
...

```

## MinIO

```

```sql
CREATE CATALOG test_iceberg_on_hms_minio_catalog PROPERTIES (
    'type' = 'iceberg',
    'iceberg.catalog.type' = 'hms',
    'warehouse' = 's3://warehouse/wh',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'fs.minio.support' = 'true',
    'minio.use_path_style' = 'true',
    'minio.endpoint' = 'http://127.0.0.1:19001',
    'minio.access_key' = '<ak>',
    'minio.secret_key' = '<sk>'
);
...

```

2.1 & 3.0 Version

HDFS

```

Access HMS and HDFS services without Kerberos authentication
```sql

 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
...

```

### OSS

```

```sql
CREATE CATALOG iceberg_hms_on_oss_catalog PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9083',
  'warehouse' = 'oss://bucket/iceberg/iceberg-hms-warehouse',
  'oss.region' = 'cn-beijing',
  'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com',
  'oss.access_key' = '<ak>',
  'oss.secret_key' = '<sk>'
);
...

```

COS

```
```sql
CREATE CATALOG `iceberg_hms_on_cos_catalog` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 'cos://bucket/iceberg-hms-cos-warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'cos.region' = 'ap-beijing',
 'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
 'cos.secret_key' = '<sk>',
 'cos.access_key' = '<ak>'
);
```
```

OBS

```
```sql
CREATE CATALOG test_iceberg_on_hms_obs_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'warehouse' = 'obs://bucket/regression/iceberg',
 'obs.region' = 'cn-north-4',
 'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
 'obs.access_key' = '<ak>',
 'obs.secret_key' = '<sk>'
);
```
```

MinIO

```
```sql
CREATE CATALOG test_iceberg_on_hms_minio_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'hms',
 'warehouse' = 's3://warehouse/iceberg',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.endpoint' = 'http://127.0.0.1:19001',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```
```

AWS Glue

3.1+ Version

S3

AWS Glue and S3 storage services share the same authentication credentials.

```
```sql
```

```
CREATE CATALOG `iceberg_glue_on_s3_catalog_` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'glue',
 'warehouse' = 's3://bucket/iceberg-glue-s3-warehouse',
 'glue.region' = 'ap-northeast-1',
 'glue.endpoint' = 'https://glue.ap-northeast-1.amazonaws.com',
 'glue.access_key' = '<ak>',
 'glue.secret_key' = '<sk>'
);
```

```

When Glue service authentication credentials differ from S3 authentication credentials, you can specify S3 authentication credentials separately using the following method.

```
```sql
CREATE CATALOG `iceberg_glue_on_s3_catalog_` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'glue',
 'warehouse' = 's3://selectdb-qa-datalake-test/iceberg-glue-s3-warehouse',
 'glue.region' = 'ap-northeast-1',
 'glue.endpoint' = 'https://glue.ap-northeast-1.amazonaws.com',
 'glue.access_key' = '<ak>',
 'glue.secret_key' = '<sk>',
 's3.endpoint' = 'https://s3.ap-northeast-1.amazonaws.com',
 's3.region' = 'ap-northeast-1',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```

```

Using IAM Assumed Role to obtain S3 access credentials (Since 3.1.2+)

```
```sql
CREATE CATALOG `glue_iceberg_iamrole` PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'glue',
 'warehouse' = 's3://bucket/warehouse',
 'glue.region' = 'us-east-1',
 'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
 'glue.role_arn' = '<role_arn>'
);
```

```

2.1 & 3.0 Version

S3

AWS Glue and S3 storage services share the same authentication credentials.

In non-EC2 environments, you need to use [aws configure] (<https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-files.html>) to configure Credentials information and generate a credentials file in the ~/.aws directory.

```
```sql
CREATE CATALOG glue PROPERTIES (
 'type'='iceberg',
 'iceberg.catalog.type' = 'glue',
 'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
 'glue.access_key' = '<ak>',
 'glue.secret_key' = '<sk>'
);
```

```

Aliyun DLF

3.1+ Version

DLF 1.0

```
```sql
CREATE CATALOG iceberg_dlf_catalog_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type'='dlf',
 'warehouse' = 'oss://bucket/iceberg-dlf-oss-warehouse',
 'dlf.uid' = '203225413946383283',
 'dlf.catalog_id' = 'p2_regression_case',
 'dlf.region' = 'cn-beijing',
 'dlf.endpoint' = 'datalake.cn-beijing.aliyuncs.com',
 'dlf.access_key' = '<ak>',
 'dlf.secret_key' = '<sk>'
);
```
```

2.1 & 3.0 Version

DLF 1.0

```
```sql
CREATE CATALOG iceberg_dlf_catalog_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type'='dlf',
 'warehouse' = 'oss://bucket/iceberg-dlf-oss-warehouse',

 'gs.endpoint'='storage.googleapis.com',
 'gs.access_key' = '<ak>',
 'gs.secret_key' = '<sk>'
);
```

```

MinIO

```

```sql
CREATE CATALOG test_iceberg_fs_on_minio PROPERTIES (
 'type' = 'iceberg',

```

```

 'iceberg.catalog.type'='hadoop',
 'warehouse' = 's3://warehouse/wh',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'http://minio:9000',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```

```

AWS S3 Tables

3.1+ Version

S3 Tables Rest Catalog

Please refer to the [S3 Tables Integration](../best-practices/doris-aws-s3tables.md) documentation.

```

```sql
CREATE CATALOG aws_s3_tables PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'rest',
 'warehouse' = 'arn:aws:s3tables:us-east-1:<account_id>:bucket/<s3_table_bucket_name>',
 'iceberg.rest.uri' = 'https://s3tables.us-east-1.amazonaws.com/iceberg',
 'iceberg.rest.sigv4-enabled' = 'true',
 'iceberg.rest.signing-name' = 's3tables',
 'iceberg.rest.signing-region' = 'us-east-1',
 'iceberg.rest.access-key-id' = '<ak>',
 'iceberg.rest.secret-access-key' = '<sk>'
);
```

```

AWS Glue Rest Catalog

Please refer to the [S3 Tables Integration](../best-practices/doris-aws-s3tables.md) documentation.

```

```sql
CREATE CATALOG glue_s3 PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 'rest',
 'iceberg.rest.uri' = 'https://glue.ap-east-1.amazonaws.com/iceberg',
 'warehouse' = '<account_id>:s3tablescatalog/<s3_table_bucket_name>',
 'iceberg.rest.sigv4-enabled' = 'true',
 'iceberg.rest.signing-name' = 'glue',
 'iceberg.rest.access-key-id' = '<ak>',
 'iceberg.rest.secret-access-key' = '<sk>',
 'iceberg.rest.signing-region' = 'ap-east-1'
);
```

```

FileSystem Catalog

Please refer to the [S3 Tables Integration](../best-practices/doris-aws-s3tables.md) documentation.

```

```sql
CREATE CATALOG test_s3tables_write_insert PROPERTIES (
 'type' = 'iceberg',

```

```

 'iceberg.catalog.type' = 's3tables',
 'warehouse' = 'arn:aws:s3tables:ap-east-1:12345:bucket/doris-s3-table-bucket',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
    ```

```

3.0.6+ Version

FileSystem Catalog

Please refer to the [S3 Tables Integration](../best-practices/doris-aws-s3tables.md) documentation.

```

```sql
CREATE CATALOG test_s3tables_catalog PROPERTIES (
 'type' = 'iceberg',
 'iceberg.catalog.type' = 's3tables',
 'warehouse' = 'arn:aws:s3tables:ap-east-1:9527:bucket/doris-s3-table-bucket',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```

```

Query Operations

Basic Query

```

-- 1. switch to catalog, use database and query
SWITCH iceberg;
USE iceberg_db;
SELECT * FROM iceberg_tbl LIMIT 10;

-- 2. use iceberg database directly
USE iceberg.iceberg_db;
SELECT * FROM iceberg_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM iceberg.iceberg_db.iceberg_tbl LIMIT 10;

```

Time Travel

You can read a specific snapshot of an Iceberg table.

By default, read requests will access the latest snapshot version.

You can query a specific snapshot of an Iceberg table using the `iceberg_meta()` table function:

```

SELECT * FROM iceberg_meta(
    'table' = 'iceberg_ctl.iceberg_db.iceberg_tbl',
    'query_type' = 'snapshots'
)\G

```

```

***** 1. row *****
committed_at: 2024-11-28 11:07:29
snapshot_id: 8903826400153112036
parent_id: -1
operation: append
manifest_list: oss://path/to/metadata/snap-8903826400153112036-1-3835e66d-9a18-4cb0-b9b0-9ec80527ad8d.avro
summary: {"added-data-files":"2","added-records":"3","added-files-size":"2742","changed-partition-

files":"0","total-position-deletes":"0","total-equality-deletes":"0"}

```

You can use the `FOR TIME AS OF` and `FOR VERSION AS OF` clauses to read historical data based on snapshot ID or the time the snapshot was created. Here are some examples:

```

-- Read data as of a specific timestamp
SELECT * FROM iceberg_table FOR TIME AS OF '2023-01-01 00:00:00';

-- Read data as of a specific snapshot ID
SELECT * FROM iceberg_table FOR VERSION AS OF 123456789;

```

Branch and Tag

Since 3.1.0

For creating, dropping and managing branch and tag, please refer to [Managing Branch & Tag](#)

Reading specific branches and tags of Iceberg tables is supported.

Multiple syntax forms are supported to be compatible with systems such as Spark/Trino.

```

-- BRANCH
SELECT * FROM iceberg_tbl@branch(branch1);
SELECT * FROM iceberg_tbl@branch("name" = "branch1");
SELECT * FROM iceberg_tbl FOR VERSION AS OF 'branch1';

-- TAG
SELECT * FROM iceberg_tbl@tag(tag1);
SELECT * FROM iceberg_tbl@tag("name" = "tag1");
SELECT * FROM iceberg_tbl FOR VERSION AS OF 'tag1';

```

For the `FOR VERSION AS OF` syntax, Doris will automatically determine whether the parameter is a timestamp or a Branch/Tag name.

View

Since 3.1.0

Supports querying Iceberg views. View queries work the same way as regular table queries. Please note the following:

- Only hms type Iceberg Catalog is supported.
- The view definition SQL must be compatible with Doris SQL dialect, otherwise parsing errors will occur. (Dialect conversion functionality will be provided in future versions).

System Tables

Since 3.1.0

Doris supports querying Iceberg system tables to retrieve metadata information about tables. You can use system tables to view snapshot history, manifest files, data files, partitions, and other metadata.

To access metadata of an Iceberg table, append a \$ symbol followed by the system table name to the table name:

```
SELECT * FROM iceberg_table$system_table_name;
```

For example, to view the table's history, you can execute:

```
SELECT * FROM iceberg_table$history;
```

Currently, the `all_manifests` and `position_deletes` system tables are not yet supported and are planned to be supported in future versions.

entries

Shows all manifest entries for the current snapshot of the table:

`all_entries` and `entries` are similar, with the difference that `all_entries` contains entries from all snapshots, while `entries` only contains entries from the current snapshot.

```
SELECT * FROM iceberg_table$entries;
```

Result:

```

-----+
| status | snapshot_id          | sequence_number | file_sequence_number | data_file
| readable_metrics
|

+-----+-----+-----+-----+-----+
|
-----+

```

files

Shows file list for the current snapshot of the table:

```
SELECT * FROM iceberg_table$files;
```

Result:

```
-----+
--+
```

Similar to the files system table, you can also query specific file type information through the following system tables:

```
-- Query data files for the current snapshot
SELECT * FROM iceberg_table$data_files;

-- Query delete files for the current snapshot
SELECT * FROM iceberg_table$delete_files;

-- Query all files (including data and delete files) from all snapshots
SELECT * FROM iceberg_table$all_files;

-- Query data files from all snapshots
SELECT * FROM iceberg_table$all_data_files;

-- Query delete files from all snapshots
SELECT * FROM iceberg_table$all_delete_files;
```

The result format of these tables is similar to the files system table, but each focuses specifically on data files or delete files. System tables with the `all_` prefix contain files from all snapshots, not just files from the current snapshot.

Note: When specific types of files do not exist in the table (for example, querying `delete_files` when there are no delete files in the table), the query result may be empty.

history

Shows all history of the table:

```
SELECT * FROM iceberg_table$history;
```

Result:

| made_current_at | snapshot_id | parent_id | is_current_ancestor |
|----------------------------|---------------------|---------------------|---------------------|
| 2025-06-12 22:29:16.357000 | 1851184769713369003 | NULL | 1 |
| 2025-06-12 22:29:39.922000 | 4890031351138056789 | 1851184769713369003 | 1 |

manifests

Shows manifest file info of the table:

```
SELECT * FROM iceberg_table$manifests;
```

Result:

| partition_spec_id | added_snapshot_id | added_data_files_count | existing_data_files_count | deleted_data_files_count | added_delete_files_count | existing_delete_files_count | deleted_delete_files_count | partition_summaries |
|-------------------|--|------------------------|---------------------------|--------------------------|--------------------------|-----------------------------|----------------------------|--|
| 0 | s3://.../iceberg_table/metadata/3194eb8b-5ea4-4cbe-95ba-073229458e7b-m0.avro | 7138 | 0 | 4890031351138056789 | 0 | 5 | 5 | 0 [{"contains_null":0, "contains_nan":0, "lower_bound":"1", "upper_bound":"10"}] |

Shows meta logs of the table:

```
SELECT * FROM iceberg_table$metadata_log_entries;
```

Result:

```
+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
| timestamp                | file                                     |

+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
```

Shows partitions of the table:

```
SELECT * FROM iceberg_table$partitions;
```

Result:

| partition | spec_id | record_count | file_count | total_data_file_size_in_bytes | position_delete_record_count | position_delete_file_count | equality_delete_record_count | equality_delete_file_count | last_updated_at | last_updated_snapshot_id |
|--------------|---------|--------------|------------|-------------------------------|------------------------------|----------------------------|------------------------------|----------------------------|----------------------------|--------------------------|
| { "id": 8 } | 0 | 1 | 1 | 625 | 0 | 0 | 0 | 0 | 2025-06-12 22:29:16.357000 | 1851184769713369003 |
| { "id": 6 } | 0 | 1 | 1 | 625 | 0 | 0 | 0 | 0 | 2025-06-12 22:29:16.357000 | 1851184769713369003 |
| { "id": 10 } | 0 | 1 | 1 | 618 | 0 | 0 | 0 | 0 | 2025-06-12 22:29:16.357000 | 1851184769713369003 |
| { "id": 4 } | 0 | 1 | 1 | 618 | 0 | 0 | 0 | 0 | 2025-06-12 22:29:16.357000 | 1851184769713369003 |
| { "id": 2 } | 0 | 1 | 1 | 611 | 0 | 0 | 0 | 0 | 2025-06-12 22:29:16.357000 | 1851184769713369003 |

Note:

- 1. For non-partitioned tables, the partitions table will not contain the partition and spec_id fields.
- 2. The partitions table shows partitions that contain data files or delete files in the current snapshot. However, delete files are not applied, so in some cases, a partition may still be displayed even if all data rows in the partition have been marked as deleted by delete files.

refs

Shows all known snapshot references (branches and tags) for the table:

```
SELECT * FROM iceberg_table$refs;
```

Result:

| name | type | snapshot_id | max_reference_age_in_ms | min_snapshots_to_keep |
|------|--------|---------------------|-------------------------|-----------------------|
| main | BRANCH | 4890031351138056789 | NULL | NULL |

snapshots

Shows all snapshots of the table:

```
SELECT * FROM iceberg_table$snapshots;
```

Result:

| committed_at | snapshot_id | parent_id | operation | manifest_list |
|----------------------------|---------------------|---------------------|-----------|---|
| summary | | | | |
| | | | | |
| | | | | |
| | | | | |
| 2025-06-12 22:29:16.357000 | 1851184769713369003 | NULL | append | s3://.../iceberg_table/metadata/snap-1851184769713369003-1-82059f57-821a-4983-b083-002cc2cde313.avro {"spark.app.id":"application_1738810850199_0472", "added-data-files":"10", "added-records":"10", "added-files-size":"6200", "changed-partition-count":"10", "total-records":"10", "total-files-size":"6200", "total-data-files":"10", "total-delete-files":"0", "total-position-deletes":"0", "total-equality-deletes":"0"} |

Write Operations

INSERT INTO

The INSERT operation appends data to the target table.

For example:

```
INSERT INTO iceberg_tbl VALUES (val1, val2, val3, val4);
INSERT INTO iceberg.iceberg_db.iceberg_tbl SELECT col1, col2 FROM internal.db1.tbl1;

INSERT INTO iceberg_tbl(col1, col2) VALUES (val1, val2);
INSERT INTO iceberg_tbl(col1, col2, partition_col1, partition_col2) VALUES (1, 2, 'beijing', '2023-12-12');
```

Since version 3.1.0, support for writing data to specified branches:

```
INSERT INTO iceberg_tbl@branch(b1) values (val1, val2, val3, val4);
INSERT INTO iceberg_tbl@branch(b1) (col3, col4) values (val3, val4);
```

INSERT OVERWRITE

The INSERT OVERWRITE operation completely replaces the existing data in the table with new data.

```
INSERT OVERWRITE TABLE iceberg_tbl VALUES (val1, val2, val3, val4);
INSERT OVERWRITE TABLE iceberg.iceberg_db.iceberg_tbl(col1, col2) SELECT col1, col2 FROM internal.db1.tbl1;
```

Since version 3.1.0, support for writing data to specified branches:

```
INSERT OVERWRITE TABLE iceberg_tbl@branch(b1) values (val1, val2, val3, val4);
INSERT OVERWRITE TABLE iceberg_tbl@branch(b1) (col3, col4) values (val3, val4);
```

CTAS

You can create an Iceberg table and write data using the CTAS (Create Table As Select) statement:

```
CREATE TABLE iceberg_ctas AS SELECT * FROM other_table;
```

CTAS supports specifying file formats, partitioning, and other properties:

```
CREATE TABLE iceberg_ctas
PARTITION BY LIST (pt1, pt2) ()
AS SELECT col1, pt1, pt2 FROM part_ctas_src WHERE col1 > 0;

CREATE TABLE iceberg.iceberg_db.iceberg_ctas (col1, col2, pt1)
PARTITION BY LIST (pt1) ()
PROPERTIES (
    'write-format'='parquet',
    'compression-codec'='zstd'
)
AS SELECT col1, pt1 AS col2, pt2 AS pt1 FROM test_ctas.part_ctas_src WHERE col1 > 0;
```

INSERT INTO BRANCH

Since 3.1.0

```
INSERT INTO iceberg_table@branch(b1) SELECT * FROM other_table;
INSERT OVERWRITE TABLE iceberg_table@branch(b1) SELECT * FROM other_table;
```

Related Parameters

- BE (Backend)

| Parameter Name | Default Value | Description |
|--|---------------|--|
| iceberg_sink_max_file_size | 1GB | Maximum data file size. When the written data exceeds this size, the current file is closed and a new file is created to continue writing. |
| table_sink_partition_write_max_partition_nums_per_writer | 128 | Maximum number of partitions each instance can write to on a BE node. |

| Parameter Name | Default Value | Description |
|---|---------------|---|
| table_sink_non_partition_write_scaling_data_processed_threshold | 25MB | Data threshold for starting scaling-write in non-partitioned tables. A new writer (instance) is used for every additional table_sink_non_partition_write_scaling_data_processed_threshold of data. This mechanism adjusts the number of writers based on data volume to enhance throughput while conserving resources and minimizing file numbers for smaller data volumes. |

| Parameter Name | Default Value | Description |
|---|---------------|---|
| table_sink_partition_write_min_data_processed_rebalance_threshold | 25MB | <p>Minimum data volume threshold to trigger rebalancing for partitioned tables. Rebalancing starts if current accumulated data volume - data volume since last rebalancing $\geq$ table_sink_partition_write_min_data_processed_rebalance_threshold.</p> <p>Lowering this threshold can improve balance if file size differences are significant, but may increase rebalancing costs and impact performance.</p> |

| Parameter Name | Default Value | Description |
|---|---------------|---|
| table_sink_partition_write_min_partition_data_processed_rebalance_threshold | | Minimum partition data volume threshold to trigger rebalancing. Rebalancing starts if current partition data volume $\geq$ threshold * number of tasks already allocated to the partition. Lowering this threshold can improve balance if file size differences are significant, but may increase rebalancing costs and impact performance. |

Database and Table Management

Creating and Dropping Databases

You can switch to the desired catalog using the SWITCH statement and execute the CREATE DATABASE command:

```
SWITCH iceberg;
CREATE DATABASE [IF NOT EXISTS] iceberg_db;
```

You can also create a database using a fully qualified name or specify a location (currently, only HMS-type catalogs support specifying a location), such as:

```
CREATE DATABASE [IF NOT EXISTS] iceberg.iceberg_db;

CREATE DATABASE [IF NOT EXISTS] iceberg.iceberg_db
PROPERTIES ( 'location'='hdfs://172.21.16.47:4007/path/to/db/');
```

You can view the database's location information using the `SHOW CREATE DATABASE` command:

```
mysql> SHOW CREATE DATABASE iceberg_db;
+-----+
---+
| Database      | Create Database
+-----+
---+
| iceberg_db    | CREATE DATABASE iceberg_db LOCATION
'hdfs://172.21.16.47:4007/usr/hive/warehouse/iceberg_db.db' |
+-----+
---+
```

To drop a database:

```
DROP DATABASE [IF EXISTS] iceberg.iceberg_db;
```

For an Iceberg Database, you must first drop all tables under the database before you can drop the database itself; otherwise, an error will occur.

Creating and Dropping Tables

- **Creating Tables**

Doris supports creating both partitioned and non-partitioned tables in Iceberg.

For example:

```
-- Create unpartitioned iceberg table
CREATE TABLE unpartitioned_table (
  `col1` BOOLEAN COMMENT 'col1',
  `col2` INT COMMENT 'col2',
  `col3` BIGINT COMMENT 'col3',
  `col4` FLOAT COMMENT 'col4',
  `col5` DOUBLE COMMENT 'col5',
  `col6` DECIMAL(9,4) COMMENT 'col6',
  `col7` STRING COMMENT 'col7',
  `col8` DATE COMMENT 'col8',
  `col9` DATETIME COMMENT 'col9'
)
PROPERTIES (
  'write-format'='parquet'
);
```

```

-- Create partitioned iceberg table
-- The partition columns must be in table's column definition list
CREATE TABLE partition_table (
  `ts` DATETIME COMMENT 'ts',
  `col1` BOOLEAN COMMENT 'col1',
  `col2` INT COMMENT 'col2',
  `col3` BIGINT COMMENT 'col3',
  `col4` FLOAT COMMENT 'col4',
  `col5` DOUBLE COMMENT 'col5',
  `col6` DECIMAL(9,4) COMMENT 'col6',
  `col7` STRING COMMENT 'col7',
  `col8` DATE COMMENT 'col8',
  `col9` DATETIME COMMENT 'col9',
  `pt1` STRING COMMENT 'pt1',
  `pt2` STRING COMMENT 'pt2'
)
PARTITION BY LIST (day(ts), pt1, pt2) ()
PROPERTIES (
  'write-format'='orc',
  'compression-codec'='zlib'
);

```

After creation, you can use the `SHOW CREATE TABLE` command to view the Iceberg table creation statement. For details about partition functions, see the [Partitioning](#) section.

• Dropping Tables

You can drop an Iceberg table using the `DROP TABLE` statement. Dropping a table will also remove its data, including partition data.

For example:

```
DROP TABLE [IF EXISTS] iceberg_tbl;
```

• Column Type Mapping

Refer to the [Column Type Mapping](#) section.

• Partitioning

Partition types in Iceberg correspond to List partitions in Doris. Therefore, when creating an Iceberg partitioned table in Doris, you should use the List partitioning syntax, but you don't need to explicitly enumerate each partition. Doris will automatically create the corresponding Iceberg partitions based on the data values during data insertion.

- Supports creating single-column or multi-column partitioned tables.
- Supports partition transformation functions to enable Iceberg implicit partitioning and partition evolution. For specific Iceberg partition transformation functions, see [Iceberg partition transforms](#):
 - `year(ts)` or `years(ts)`
 - `month(ts)` or `months(ts)`
 - `day(ts)` or `days(ts)` or `date(ts)`
 - `hour(ts)` or `hours(ts)` or `date_hour(ts)`

- `bucket(N, col)`
- `truncate(L, col)`

- **File Formats**

- Parquet (default)

Note that for the Iceberg table created by Doris, the Datetime corresponds to the `timestamp_ntz` type.

In versions after 3.1.0, when the Datetime type is written to the Parquet file, the physical type used is INT64 instead of INT96.

And if the Iceberg table is created by other systems, although the `timestamp` and `timestamp_ntz` types are both mapped to the Doris Datetime type. However, when writing, it will determine whether the time zone needs to be processed based on the actual type.

- ORC

- **Compression Formats**

- Parquet: snappy, zstd (default), plain (no compression).
- ORC: snappy, zlib (default), zstd, plain (no compression).

- **Storage Medium**

- HDFS
- Object storage

Schema Change

Start from 3.1.0, Doris supports schema changes for Iceberg tables, which can be modified using the ALTER TABLE statement.

Supported schema change operations include:

- **Rename Column**

Use the `RENAME COLUMN` clause to rename columns. Renaming columns within nested types is not supported.

```
ALTER TABLE iceberg_table RENAME COLUMN old_col_name TO new_col_name;
```

- **Add a Column**

Use `ADD COLUMN` to add a new column. Adding new columns to nested types is not supported.

When adding a new column, you can specify nullable attributes, default values, comments, and column position.

```
ALTER TABLE iceberg_table ADD COLUMN col_name col_type [NULL|NOT NULL, [DEFAULT default_value,
[COMMENT 'comment', [FIRST|AFTER col_name]]]]];
```

Example:

```
ALTER TABLE iceberg_table ADD COLUMN new_col STRING NOT NULL DEFAULT 'default_value' COMMENT 'This is
a new col' AFTER old_col;
```

- **Add Columns**

You can also use `ADD COLUMN` to add multiple columns. The new columns will be added to the end of the table. Column positioning is not supported for multiple columns. Adding new columns to nested types is not supported.

The syntax for each column is the same as adding a single column.

```
ALTER TABLE iceberg_table ADD COLUMN (col_name1 col_type1 [NULL|NOT NULL, [DEFAULT default_value,
[COMMENT 'comment']]], col_name2 col_type2 [NULL|NOT NULL, [DEFAULT default_value, [COMMENT
'comment']]] ...);
```

- **Drop Column**

Use `DROP COLUMN` to drop columns. Dropping columns within nested types is not supported.

```
ALTER TABLE iceberg_table DROP COLUMN col_name;
```

- **Modify Column**

Use the `MODIFY COLUMN` statement to modify column attributes, including type, nullable, default value, comment, and column position.

Note: When modifying column attributes, all attributes that are not being modified should also be explicitly specified with their original values.

```
ALTER TABLE iceberg_table MODIFY COLUMN col_name col_type [NULL|NOT NULL, [DEFAULT default_value,
[COMMENT 'comment', [FIRST|AFTER col_name]]]]];
```

Example:

```
CREATE TABLE iceberg_table (
  id INT,
  name STRING
);
-- Modify the id column type to BIGINT, set as NOT NULL, default value to 0, and add comment
ALTER TABLE iceberg_table MODIFY COLUMN id BIGINT NOT NULL DEFAULT 0 COMMENT 'This is a modified id
column';
```

- **Reorder Columns**

Use `ORDER BY` to reorder columns by specifying the new column order.

```
ALTER TABLE iceberg_table ORDER BY (col_name1, col_name2, ...);
```

Partition Evolution

Starting from version 4.0.2, Doris supports Partition Evolution for Iceberg tables through ALTER statements.

Supported partition transforms include:

| Transform | Syntax | Example |
|-----------|---------------------|--------------------|
| bucket | bucket(N, column) | bucket(16, id) |
| truncate | truncate(N, column) | truncate(10, name) |
| year | year(column) | year(ts) |
| month | month(column) | month(ts) |
| day | day(column) | day(ts) |
| hour | hour(column) | hour(ts) |
| identity | column | category |

Supported operations include:

- **Add partition key**

```
-- use optional AS keyword to specify a custom name for the partition field
ALTER TABLE table_name ADD PARTITION KEY partition_transform [AS key_name];

-- example
ALTER TABLE prod.db.sample ADD PARTITION KEY bucket(16, id);
ALTER TABLE prod.db.sample ADD PARTITION KEY truncate(4, data);
ALTER TABLE prod.db.sample ADD PARTITION KEY year(ts);
-- use optional AS keyword to specify a custom name for the partition field
ALTER TABLE prod.db.sample ADD PARTITION KEY bucket(16, id) AS shard;
```

- **Drop partition key**

```
ALTER TABLE table_name DROP PARTITION KEY partition_transform | key_name;

-- example
ALTER TABLE prod.db.sample DROP PARTITION KEY catalog;
ALTER TABLE prod.db.sample DROP PARTITION KEY bucket(16, id);
ALTER TABLE prod.db.sample DROP PARTITION KEY truncate(4, data);
ALTER TABLE prod.db.sample DROP PARTITION KEY year(ts);
ALTER TABLE prod.db.sample DROP PARTITION KEY shard;
```

- **Replace partition key**

```
-- use optional AS keyword to specify a custom name for the partition field
ALTER TABLE table_name REPLACE PARTITION KEY key_name WITH partition_transform [AS key_name];

-- example
ALTER TABLE prod.db.sample REPLACE PARTITION KEY ts_day WITH day(ts);
```

```
-- use optional AS keyword to specify a custom name for the new partition field
ALTER TABLE prod.db.sample REPLACE PARTITION KEY ts_day WITH day(ts) AS day_of_ts;
```

Managing Branch & Tag

Since 3.1.0

- **Create Branch**

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
CREATE [OR REPLACE] BRANCH [IF NOT EXISTS] <branch_name>
[AS OF VERSION <snapshot_id>]
[RETAIN <num> { DAYS | HOURS | MINUTES }]
[WITH SNAPSHOT RETENTION { snapshotKeep | timeKeep }]
```

snapshotKeep:

```
<num> SNAPSHOTS [<num> { DAYS | HOURS | MINUTES }]
```

timeKeep:

```
<num> { DAYS | HOURS | MINUTES }
```

Examples:

```
-- Create branch "b1".
ALTER TABLE tbl CREATE BRANCH b1;
ALTER TABLE tb1 CREATE BRANCH IF NOT EXISTS b1;
-- Create or replace branch "b1".
ALTER TABLE tb1 CREATE OR REPLACE BRANCH b1;
-- Create or replace branch "b1" based on snapshot "123456".
ALTER TABLE tb1 CREATE OR REPLACE BRANCH b1 AS OF VERSION 123456;
-- Create or replace branch "b1" based on snapshot "123456", branch retained for 1 day.
ALTER TABLE tb1 CREATE OR REPLACE BRANCH b1 AS OF VERSION 123456 RETAIN 1 DAYS;
-- Create branch "b1" based on snapshot "123456", branch retained for 30 days. Keep the latest 3
snapshots in the branch.
ALTER TABLE tb1 CREATE BRANCH b1 AS OF VERSION 123456 RETAIN 30 DAYS WITH SNAPSHOT RETENTION 3
SNAPSHOTS;
-- Create branch "b1" based on snapshot "123456", branch retained for 30 days. Snapshots in the branch
are retained for at most 2 days.
ALTER TABLE tb1 CREATE BRANCH b1 AS OF VERSION 123456 RETAIN 30 DAYS WITH SNAPSHOT RETENTION 2 DAYS;
-- Create branch "b1" based on snapshot "123456", branch retained for 30 days. Keep the latest 3
snapshots in the branch, and snapshots in the branch are retained for at most 2 days.
ALTER TABLE tb1 CREATE BRANCH b1 AS OF VERSION 123456 RETAIN 30 DAYS WITH SNAPSHOT RETENTION 3
SNAPSHOTS 2 DAYS;
```

- **Drop Branch**

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
DROP BRANCH [IF EXISTS] <branch_name>;
```

Example:

```
ALTER TABLE tbl DROP BRANCH b1;
```

- **Create Tag**

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
CREATE [OR REPLACE] TAG [IF NOT EXISTS] <tag_name>
[AS OF VERSION <snapshot_id>]
[RETAIN <num> { DAYS | HOURS | MINUTES }]
```

Examples:

```
-- Create tag "t1".
ALTER TABLE tbl CREATE TAG t1;
ALTER TABLE tb1 CREATE TAG IF NOT EXISTS t1;
-- Create or replace tag "t1".
ALTER TABLE tb1 CREATE OR REPLACE TAG t1;
-- Create or replace tag "t1" based on snapshot "123456".
ALTER TABLE tb1 CREATE OR REPLACE TAG b1 AS OF VERSION 123456;
-- Create or replace tag "b1" based on snapshot "123456", tag retained for 1 day.
ALTER TABLE tb1 CREATE OR REPLACE TAG b1 AS OF VERSION 123456 RETAIN 1 DAYS;
```

- **Drop Tag**

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
DROP TAG [IF EXISTS] <tag_name>;
```

Example:

```
ALTER TABLE tbl DROP TAG t1;
```

Iceberg Table Actions

This feature is supported since 4.0.2

This is an experimental feature.

Doris supports executing specific actions on Iceberg tables through the ALTER TABLE EXECUTE syntax. This syntax provides a unified interface for executing various actions such as table optimization and snapshot management.

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE <action_name> ("key1" = "value1", "key2" = "value2", ...)
[WHERE <condition>]
```

- **action_name**: The name of the action to execute

- ("key1" = "value1", ...): Action-related parameters provided as key-value pairs. Parameter names must be wrapped in double quotes
- [WHERE <condition>]: Optional WHERE condition to specify the partition or data range for the operation (only supported by some operations)

rewrite_data_files

The `rewrite_data_files` operation rewrites data files in an Iceberg table to implement small file compaction, optimizing query performance and storage efficiency. This is a synchronized operation.

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE rewrite_data_files ("key1" = "value1", "key2" = "value2", ...) [WHERE <condition>]
```

Parameters:

| Parameter Name | Type | Default Value | Description |
|---------------------------|---------|-------------------------------|--|
| target-file-size-bytes | Long | 536870912 (512MB) | Target file size in bytes for output files |
| min-file-size-bytes | Long | target-file-size-bytes * 0.75 | Minimum file size in bytes. Files smaller than this will be rewritten. If not specified, defaults to 75% of target file size |
| max-file-size-bytes | Long | target-file-size-bytes * 1.8 | Maximum file size in bytes. Files larger than this will be split. If not specified, defaults to 180% of target file size |
| min-input-files | Integer | 5 | Minimum number of input files to trigger rewrite. Rewrite only executes when the number of files to rewrite reaches this threshold |
| rewrite-all | Boolean | false | Whether to rewrite all files regardless of file size |
| max-file-group-size-bytes | Long | 107374182400 (100GB) | Maximum size in bytes for a file group. Used to limit the amount of data processed by a single rewrite task |
| delete-file-threshold | Integer | Integer.MAX_VALUE | Minimum number of delete files required to trigger rewrite |
| delete-ratio-threshold | Double | 0.3 | Minimum ratio of delete records to total records required to trigger rewrite (delete records / total records). Range: 0.0 - 1.0 |
| output-spec-id | Long | 2 | Partition specification ID for output files |

Return Value:

Executing `rewrite_data_files` returns a result set with the following 4 columns:

| Column Name | Type | Description |
|---|--------|--|
| <code>rewritten_data_files_count</code> | INT | Number of data files that were rewritten |
| <code>added_data_files_count</code> | INT | Number of new data files that were written |
| <code>rewritten_bytes_count</code> | INT | Number of bytes that were rewritten |
| <code>removed_delete_files_count</code> | BIGINT | Number of delete files that were removed |

Examples:

```
-- Rewrite data files with default parameters
ALTER TABLE iceberg_db.iceberg_table EXECUTE rewrite_data_files();

-- Specify target file size and minimum input files
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rewrite_data_files (
  "target-file-size-bytes" = "134217728",
  "min-input-files" = "10"
);

-- Use WHERE condition to rewrite specific partition data
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rewrite_data_files (
  "target-file-size-bytes" = "268435456"
)
WHERE date_col = '2024-01-01';

-- Rewrite all files
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rewrite_data_files (
  "rewrite-all" = "true",
  "target-file-size-bytes" = "536870912"
);
```

Notes:

1. The `rewrite_data_files` operation reads and rewrites data files, which will generate additional I/O and computational overhead. Please allocate cluster resources reasonably.
2. Before execution, you can use the SQL in the [View Data File Distribution](#) section to evaluate whether a rewrite operation is needed
3. The WHERE condition can be used to limit the partition or data range for rewriting. This condition will filter out files that do not contain data matching the WHERE condition, thereby reducing the number of files and amount of data to rewrite
4. Before execution, you can use the SQL in the [Rewrite File Selection Logic](#) section to calculate which files will be rewritten

cherrypick_snapshot

The `cherrypick_snapshot` operation merges changes from a specified snapshot into the current table state, creating a new snapshot without modifying or deleting the original snapshot.

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE cherrypick_snapshot ("snapshot_id" = "<snapshot_id>")
```

Parameters:

| Parameter Name | Type | Required | Description |
|----------------|------|----------|--------------------------|
| snapshot_id | Long | Yes | The snapshot ID to merge |

Return Value:

Executing `cherrypick_snapshot` returns a result set with the following 2 columns:

| Column Name | Type | Description |
|---------------------|--------|--|
| source_snapshot_id | BIGINT | The snapshot ID whose changes were merged |
| current_snapshot_id | BIGINT | The snapshot ID of the new snapshot created and set as current after the merge operation |

Example:

```
-- Merge changes from snapshot 123456789 into current table state
ALTER TABLE iceberg_db.iceberg_table
EXECUTE cherrypick_snapshot ("snapshot_id" = "123456789");
```

Notes:

1. This operation does not support WHERE conditions
2. If the specified snapshot does not exist, the operation will fail
3. The merge operation creates a new snapshot and does not delete the original snapshot

fast_forward

The `fast_forward` operation fast-forwards the current snapshot of one branch to the latest snapshot of another branch.

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE fast_forward ("branch" = "<branch_name>", "to" = "<target_branch>")
```

Parameters:

| Parameter Name | Type | Required | Description |
|----------------|--------|----------|---|
| branch | String | Yes | Name of the branch to fast-forward |
| to | String | Yes | Target branch name. The branch will be fast-forwarded to the latest snapshot of this branch |

Return Value:

Executing `fast_forward` returns a result set with the following 3 columns:

| Column Name | Type | Description |
|----------------|--------|--|
| branch_updated | STRING | Name of the branch that was fast-forwarded |
| previous_ref | BIGINT | Snapshot ID the branch was pointing to before the fast-forward operation (can be NULL) |
| updated_ref | BIGINT | Snapshot ID the branch is pointing to after the fast-forward operation |

Example:

```
-- Fast-forward feature branch to the latest snapshot of main branch
ALTER TABLE iceberg_db.iceberg_table
EXECUTE fast_forward ("branch" = "feature", "to" = "main");
```

Notes:

1. This operation does not support WHERE conditions
2. If the specified branch does not exist, the operation will fail
3. Only branches can be fast-forwarded, not tags

rollback_to_snapshot

The `rollback_to_snapshot` operation rolls back an Iceberg table to a specified snapshot.

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE rollback_to_snapshot ("snapshot_id" = "<snapshot_id>")
```

Parameters:

| Parameter Name | Type | Required | Description |
|----------------|------|----------|--------------------------------|
| snapshot_id | Long | Yes | The snapshot ID to rollback to |

Return Value:

Executing `rollback_to_snapshot` returns a result set with the following 2 columns:

| Column Name | Type | Description |
|----------------------|--------|---|
| previous_snapshot_id | BIGINT | The snapshot ID that was current before the rollback operation |
| current_snapshot_id | BIGINT | The snapshot ID that is set as current after rolling back to the specified snapshot |

Example:

```
-- Rollback to snapshot 987654321
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rollback_to_snapshot ("snapshot_id" = "987654321");
```

Notes:

1. This operation does not support WHERE conditions
2. If the specified snapshot does not exist, the operation will fail
3. If the current snapshot is already the target snapshot, the operation returns directly without creating a new snapshot

rollback_to_timestamp

The `rollback_to_timestamp` operation rolls back an Iceberg table to the snapshot at a specified timestamp.

Syntax:

```
ALTER TABLE [catalog.][database.]table_name
EXECUTE rollback_to_timestamp ("timestamp" = "<timestamp>")
```

Parameters:

| Parameter Name | Type | Required | Description |
|----------------|--------|----------|---|
| timestamp | String | Yes | The timestamp to rollback to. Supports two formats:
1. ISO datetime format: yyyy-MM-dd HH:mm:ss.SSS (e.g., 2024-01-01 10:30:00.000)
2. Milliseconds timestamp (e.g., 1704067200000) |

Return Value:

Executing `rollback_to_timestamp` returns a result set with the following 2 columns:

| Column Name | Type | Description |
|----------------------|--------|---|
| previous_snapshot_id | BIGINT | The snapshot ID that was current before the rollback operation |
| current_snapshot_id | BIGINT | The snapshot ID that was current at the specified timestamp, now set as current |

Examples:

```
-- Rollback to specified timestamp (ISO format)
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rollback_to_timestamp ("timestamp" = "2024-01-01 10:30:00.000");

-- Rollback to specified timestamp (timestamp format)
ALTER TABLE iceberg_db.iceberg_table
EXECUTE rollback_to_timestamp ("timestamp" = "1704067200000");
```

Notes:

1. This operation does not support WHERE conditions
2. The timestamp parameter supports ISO datetime format (yyyy-MM-dd HH:mm:ss.SSS) or milliseconds timestamp format
3. If there is no snapshot corresponding to the specified timestamp, the operation will fail

set_current_snapshot

The set_current_snapshot operation sets the current snapshot of an Iceberg table to a specified snapshot ID or reference (branch or tag).

Syntax:

```
ALTER TABLE [catalog.][database.]table_name  
EXECUTE set_current_snapshot ("snapshot_id" = "<snapshot_id>" | "ref" = "<ref_name>")
```

Parameters:

| Parameter Name | Type | Required | Description |
|----------------|--------|------------|--|
| snapshot_id | Long | Either one | The snapshot ID to set as current |
| ref | String | Either one | The reference name (branch or tag) to set as current |

Return Value:

Executing set_current_snapshot returns a result set with the following 2 columns:

| Column Name | Type | Description |
|----------------------|--------|--|
| previous_snapshot_id | BIGINT | The snapshot ID that was current before setting the new current snapshot |
| current_snapshot_id | BIGINT | The snapshot ID that is now set as current (from snapshot_id parameter or resolved from ref parameter) |

Examples:

```
-- Set current snapshot by snapshot ID  
ALTER TABLE iceberg_db.iceberg_table  
EXECUTE set_current_snapshot ("snapshot_id" = "123456789");  
  
-- Set current snapshot by branch name  
ALTER TABLE iceberg_db.iceberg_table  
EXECUTE set_current_snapshot ("ref" = "feature_branch");  
  
-- Set current snapshot by tag name  
ALTER TABLE iceberg_db.iceberg_table  
EXECUTE set_current_snapshot ("ref" = "v1.0");
```

Notes:

1. This operation does not support WHERE conditions
2. The snapshot_id and ref parameters are mutually exclusive; only one can be specified
3. If the specified snapshot ID or reference does not exist, the operation will fail
4. If the current snapshot is already the target snapshot, the operation returns directly without creating a new snapshot

Iceberg Table Optimization

View Data File Distribution

You can use the following SQL to analyze the data distribution and delete file count of Iceberg tables, helping determine whether optimization like `rewrite_data_files` is needed.

- Display data file size distribution. This can help identify if there are too many

```
SELECT
  CASE
    WHEN file_size_in_bytes BETWEEN 0 AND 8 * 1024 * 1024 THEN '0-8M'
    WHEN file_size_in_bytes BETWEEN 8 * 1024 * 1024 + 1 AND 32 * 1024 * 1024 THEN '8-32M'
    WHEN file_size_in_bytes BETWEEN 32 * 1024 * 1024 + 1 AND 128 * 1024 * 1024 THEN '32-128M'
    WHEN file_size_in_bytes BETWEEN 128 * 1024 * 1024 + 1 AND 512 * 1024 * 1024 THEN '128-512M'
    WHEN file_size_in_bytes > 512 * 1024 * 1024 THEN '> 512M'
    ELSE 'Unknown'
  END AS SizeRange,
  COUNT(*) AS FileNum
FROM store_sales$data_files
GROUP BY
  SizeRange;
```

| SizeRange | FileNum |
|-----------|---------|
| 0-8M | 8 |
| 8-32M | 6 |

- Display the number of data files and delete files

```
SELECT
  CASE
    WHEN content = 0 THEN 'DataFile'
    WHEN content = 1 THEN 'PositionDeleteFile'
    WHEN content = 2 THEN 'EqualityDeleteFile'
    ELSE 'Unknown'
  END AS ContentType,
  COUNT(*) AS FileNum,
  SUM(file_size_in_bytes) AS SizeInBytes,
  SUM(record_count) AS Records
FROM iceberg_table$files
GROUP BY
  ContentType;
```

| ContentType | FileNum | SizeInBytes | Records |
|--------------------|---------|-------------|---------|
| EqualityDeleteFile | 2787 | 1432518 | 27870 |
| DataFile | 2787 | 4062416 | 38760 |

| | | | |
|-------------------------|----|-------|-------|
| PositionDeleteFile | 11 | 36608 | 10890 |
| -----+-----+-----+----- | | | |

Dangling Delete

In some cases, after executing the `rewrite_data_files` action, references to certain Position Deletes may not have been removed from the Snapshot metadata (Dangling Delete). If you directly use the row number information from the metadata in this situation, the result may be incorrect.

Therefore, by default, for `COUNT(*)` queries, if a Position Delete file is found, COUNT pushdown optimization is not enabled; instead, the file is read directly to obtain the actual `COUNT(*)` result. However, this method is time-consuming.

If the user can ensure there is no Dangling Delete issue, this check can be skipped using the Doris session variable `ignore_iceberg_dangling_delete`. This variable defaults to `false`. When set to `true`, the system will directly return the `COUNT(*)` result based on the row count information in the metadata, improving query efficiency.

This feature is supported from versions 3.1.4 and 4.0.3.

Appendix

`rewrite_data_files` File Selection Strategy

You can check this section to understand the logic for selecting files to be rewritten. You can also use the following SQL queries to analyze which files will be rewritten based on system table information. This helps you debug and understand rewrite behavior before executing actual rewrite operations.

The rewrite operation uses a two-stage filtering and grouping strategy:

1. Stage 1: File-level filtering

First, files are filtered based on file-level conditions. Only files that meet at least one of the following conditions will be considered for rewriting:

1. **File size out of range:** File is smaller than `min-file-size-bytes` or larger than `max-file-size-bytes`
2. **Too many delete files:** Number of associated delete files $\geq$ `delete-file-threshold`
3. **High delete ratio:** Delete record ratio $\geq$ `delete-ratio-threshold`

Note about delete file conditions: Conditions related to delete files (`delete-file-threshold` and `delete-ratio-threshold`) affect file rewrite selection, but cannot be accurately calculated through system table SQL queries. This is because current system table information is insufficient to accurately determine which data files are affected by delete files. Delete files may only affect specific data files (especially Position Delete files), and the association between delete files and data files requires more detailed metadata that is not available in current system tables. Actual rewrite operations will evaluate these conditions based on more detailed metadata not exposed in system tables.

2. Stage 2: BinPack grouping and group-level filtering

```
| s3a://bucket/path/to/table/data/date_col=2024-01-02/00002-0-00002-00002-0.parquet |
{"date_col":"2024-01-02"} | 0.00231 | 5 | Too small |
| s3a://bucket/path/to/table/data/date_col=2024-01-02/00003-0-00003-00003-0.parquet |
{"date_col":"2024-01-02"} | 850.23456 | 1250000 | Too large |
| s3a://bucket/path/to/table/data/date_col=2024-01-03/00004-0-00004-00004-0.parquet |
{"date_col":"2024-01-03"} | 0.00245 | 5 | Too small |
+-----+-----+-----+-----+
5 rows in set
```

Note: This query can only identify files that meet file-level conditions (file size). The actual file groups to be rewritten depend on the BinPack grouping algorithm, which cannot be accurately simulated through SQL queries. Files identified by this query may be grouped differently by the BinPack algorithm, and some groups may be filtered out based on group-level conditions.

- Query 2: Overall statistics summary

This query provides overall statistics about files that meet file-level conditions:

```
-- Set parameters (adjust according to your rewrite parameters)
SET @min_file_size_bytes = 16 * 1024 * 1024;
SET @max_file_size_bytes = 768 * 1024 * 1024;

WITH file_analysis AS (
  SELECT
    `partition`,
    file_path,
    file_size_in_bytes,
    record_count,
    (file_size_in_bytes < @min_file_size_bytes OR file_size_in_bytes > @max_file_size_bytes) AS
meets_file_level_conditions
  FROM iceberg_table$data_files
)
SELECT
  'Total files' AS metric,
  COUNT(*) AS value
FROM file_analysis
UNION ALL
SELECT
  'Files meeting file-level conditions',
  SUM(CASE WHEN meets_file_level_conditions THEN 1 ELSE 0 END)
FROM file_analysis
UNION ALL
SELECT
  'Total size (GB)',
  ROUND(SUM(file_size_in_bytes) / 1024.0 / 1024.0 / 1024.0, 2)
FROM file_analysis
UNION ALL
SELECT
  'Size meeting file-level conditions (GB)',
  ROUND(SUM(CASE WHEN meets_file_level_conditions THEN file_size_in_bytes ELSE 0 END) / 1024.0 /
1024.0 / 1024.0, 2)
FROM file_analysis
UNION ALL
SELECT
  'Percentage meeting file-level conditions (%)',
  ROUND(SUM(CASE WHEN meets_file_level_conditions THEN 1 ELSE 0 END) * 100.0 / COUNT(*), 2)
FROM file_analysis;
```

Sample output:

| metric | value |
|--|-------|
| Total files | 15.00 |
| Total size (GB) | 2.45 |
| Files meeting file-level conditions | 12.00 |
| Size meeting file-level conditions (GB) | 1.85 |
| Percentage meeting file-level conditions (%) | 80.00 |

5 rows in set

Notes:

- Replace `iceberg_table` in the example with the actual table name
- Adjust parameter values (`@min_file_size_bytes`, `@max_file_size_bytes`) according to your actual rewrite parameters
- The default values shown above correspond to default rewrite parameters (`min-file-size-bytes = target-file-size-bytes * 0.75`, `max-file-size-bytes = target-file-size-bytes * 1.8`)
- View snapshot and branch relationships

```

Hudi Catalog

Hudi Catalog reuses the Hive Catalog. By connecting to the Hive Metastore, or a metadata service compatible with the Hive Metastore, Doris can automatically obtain Hudi's database and table information and perform data queries.

[Quick start with Apache Doris and Apache Hudi.](#)

Applicable Scenarios

| Scenario | Description |
|--------------------|---|
| Query Acceleration | Use Doris's distributed computing engine to directly access Hudi data for query acceleration. |
| Data Integration | Read Hudi data and write it into Doris internal tables, or perform ZeroETL operations using the Doris computing engine. |
| Data Write-back | Not supported. |

Configuring Catalog

Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (  
  'type' = 'hms', -- required  
  'hive.metastore.uris' = '<metastore_thrift_url>', -- required  
  {MetaStoreProperties},  
  {StorageProperties},  
  {HudiProperties},  
  {CommonProperties}  
);
```

- [MetaStoreProperties]

The MetaStoreProperties section is used to fill in the connection and authentication information for the Metastore metadata service. See the section [Supported Metadata Services](#) for details.

- [StorageProperties]

The StorageProperties section is used to fill in the connection and authentication information related to the storage system. See the section [Supported Storage Systems](#) for details.

- [CommonProperties]

The CommonProperties section is used to fill in common properties. Please refer to the [Data Catalog Overview](#) section on [Common Properties].

- {HudiProperties}

| Parameter Name | Former Name | Description | Default Value |
|-------------------------------|-------------------------|--|---------------|
| hoodi.use_hive_sync_partition | use_hive_sync_partition | Whether to use the partition information already synchronized by Hive Metastore. If true, partition information will be obtained directly from Hive Metastore. Otherwise, it will be obtained from the metadata file of the file system. Obtaining information from Hive Metastore is more efficient, but users need to ensure that the latest metadata has been synchronized to Hive Metastore. | false |

Supported Hudi Versions

The current dependent Hudi version is 0.15. It is recommended to access Hudi data version 0.14 and above.

Supported Query Types

| Table Type | Supported Query Types |
|---------------|---|
| Copy On Write | Snapshot Query, Time Travel, Incremental Read |
| Merge On Read | Snapshot Queries, Read Optimized Queries, Time Travel, Incremental Read |

Supported Metadata Services

- [Hive Metastore](#)

Supported Storage Systems

- [HDFS](#)
- [AWS S3](#)
- [Google Cloud Storage](#)
- [Alibaba Cloud OSS](#)
- [Tencent Cloud COS](#)
- [Huawei Cloud OBS](#)
- [MINIO](#)

Supported Data Formats

- [Parquet](#)
- [ORC](#)

Column Type Mapping

| Hudi Type | Doris Type | Comment |
|-----------|------------|---------|
| boolean | boolean | |
| int | int | |
| long | bigint | |

| Hudi Type | Doris Type | Comment |
|---------------|---------------|---|
| float | float | |
| double | double | |
| decimal(P, S) | decimal(P, S) | |
| bytes | string | |
| string | string | |
| date | date | |
| timestamp | datetime(N) | Automatically maps to datetime(3) or datetime(6) based on precision |
| array | array | |
| map | map | |
| struct | struct | |
| other | UNSUPPORTED | |

Examples

The creation of a Hudi Catalog is similar to a Hive Catalog. For more examples, please refer to [Hive Catalog](#).

```
CREATE CATALOG hudi_hms PROPERTIES (
  'type'='hms',
  'hive.metastore.uris' = 'thrift://172.21.0.1:7004',
  'hadoop.username' = 'hive',
  'dfs.nameservices'='your-nameservice',
  'dfs.ha.namenodes.your-nameservice'='nn1,nn2',
  'dfs.namenode.rpc-address.your-nameservice.nn1'='172.21.0.2:4007',
  'dfs.namenode.rpc-address.your-nameservice.nn2'='172.21.0.3:4007',
  'dfs.client.failover.proxy.provider.your-
nameservice'='org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider'
);
```

Query Operations

Basic Query

Once the Catalog is configured, you can query the tables within the Catalog using the following method:

```
-- 1. switch to catalog, use database and query
SWITCH hudi_ctl;
USE hudi_db;
SELECT * FROM hudi_tbl LIMIT 10;

-- 2. use hudi database directly
USE hudi_ctl.hudi_db;
SELECT * FROM hudi_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM hudi_ctl.hudi_db.hudi_tbl LIMIT 10;
```

Time Travel

Every write operation to a Hudi table creates a new snapshot. Doris supports reading a specified snapshot of a Hudi table. By default, query requests only read the latest snapshot.

You can query the timeline of a specified Hudi table using the `hudi_meta()` table function:

This table function is supported since 3.1.0.

```
SELECT * FROM hudi_meta(  
  'table' = 'hudi_ctl.hudi_db.hudi_tbl',  
  'query_type' = 'timeline'  
);
```

| timestamp | action | file_name | state | state_transition_time |
|-------------------|--------|--------------------------|-----------|-----------------------|
| 20241202171214902 | commit | 20241202171214902.commit | COMPLETED | 20241202171215756 |
| 20241202171217258 | commit | 20241202171217258.commit | COMPLETED | 20241202171218127 |
| 20241202171219557 | commit | 20241202171219557.commit | COMPLETED | 20241202171220308 |
| 20241202171221769 | commit | 20241202171221769.commit | COMPLETED | 20241202171222541 |
| 20241202171224269 | commit | 20241202171224269.commit | COMPLETED | 20241202171224995 |
| 20241202171226401 | commit | 20241202171226401.commit | COMPLETED | 20241202171227155 |
| 20241202171228827 | commit | 20241202171228827.commit | COMPLETED | 20241202171229570 |
| 20241202171230907 | commit | 20241202171230907.commit | COMPLETED | 20241202171231686 |
| 20241202171233356 | commit | 20241202171233356.commit | COMPLETED | 20241202171234288 |
| 20241202171235940 | commit | 20241202171235940.commit | COMPLETED | 20241202171236757 |

You can use the `FOR TIME AS OF` statement to read historical versions of data based on the snapshot's timestamp. The time format is consistent with the Hudi documentation. Here are some examples:

```
SELECT * FROM hudi_tbl FOR TIME AS OF "2022-10-07 17:20:37";  
SELECT * FROM hudi_tbl FOR TIME AS OF "20221007172037";  
SELECT * FROM hudi_tbl FOR TIME AS OF "2022-10-07";
```

Note that Hudi tables do not support the `FOR VERSION AS OF` statement. Attempting to use this syntax with a Hudi table will result in an error.

Incremental Query

Incremental Read allows querying data changes within a specified time range, returning the final state of the data at the end of that period.

Doris provides the `@incr` syntax to support Incremental Read:

```
SELECT * from hudi_table@incr('beginTime'='xxx', ['endTime'='xxx'],  
  ['hoodie.read.timeline.holes.resolution.policy'='FAIL'], ...);
```

- `beginTime`

Required. The time format must be consistent with the Hudi official [hudi_table_changes](#), supporting “earliest”.

- endTime

Optional, defaults to the latest commitTime.

You can add more options in the @incr function, compatible with [Spark Read Options](#).

By using desc to view the execution plan, you can see that Doris converts @incr into predicates pushed down to VHUDI_SCAN_NODE:

```
| 0:VHUDI_SCAN_NODE(113)
|
|   table: lineitem_mor
|
|   predicates: (_hoodie_commit_time[#0] > '20240311151019723'), (_hoodie_commit_time[#0] <=
'20240311151606605') |
|   inputSplitNum=1, totalFileSize=13099711, scanRanges=1
```

FAQ

1. Query blocked when using Java SDK to read incremental data through JNI

Please add -Djol.skipHotspotSAAttach=true to JAVA_OPTS_FOR_JDK_17 or JAVA_OPTS in be.conf.

Appendix

Change Log

| Doris Version | Feature Support |
|---------------|--|
| 2.1.8/3.0.4 | Hudi dependency upgraded to 0.15. Added Hadoop Hudi JNI Scanner. |

Paimon Catalog

Doris currently supports accessing Paimon table metadata through various metadata services and querying Paimon data.

At present, only read operations on Paimon tables are supported. Write operations to Paimon tables will be supported in the future.

[Quick start with Apache Doris and Apache Paimon.](#)

Applicable Scenarios

| Scenario | Description |
|--------------------|---|
| Query Acceleration | Use Doris's distributed computing engine to directly access Paimon data for query acceleration. |
| Data Integration | Read Paimon data and write it into Doris internal tables, or perform ZeroETL operations using the Doris computing engine. |
| Data Write-back | Not supported yet. |

Configuring Catalog

Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (  
  'type' = 'paimon',  
  'paimon.catalog.type' = '<paimon_catalog_type>',  
  'warehouse' = '<paimon_warehouse>'  
  {MetaStoreProperties},  
  {StorageProperties},  
  {PaimonProperties},  
  {CommonProperties}  
);
```

- <paimon_catalog_type>

The type of Paimon Catalog, supporting the following:

- filesystem: Default. Directly accesses metadata stored on the file system.
- hms: Uses Hive Metastore as the metadata service.
- dlf: Uses Alibaba Cloud DLF as the metadata service.

- <paimon_warehouse>

The warehouse path for Paimon. This parameter must be specified when <paimon_catalog_type> is filesystem.

The warehouse path must point to the level above the Database path. For example, if your table path is: s3://bucket/path/to/db1/table1, then warehouse should be: s3://bucket/path/to/.

- {MetaStoreProperties}

The MetaStoreProperties section is used to fill in connection and authentication information for the Metastore metadata service. Refer to the section on [Supported Metadata Services](#) for details.

- {StorageProperties}

The StorageProperties section is used to fill in connection and authentication information related to the storage system. Refer to the section on [Supported Storage Systems](#) for details.

- {PaimonProperties}

The PaimonProperties section is used to fill Paimon-related properties.

When Doris accesses Paimon metadata, it partially uses the Paimon Java SDK, so some custom parameters may need to be passed through to the Paimon Java SDK. You can use the following prefixes:

```
paimon.s3.xxx  
paimon.s3a.xxx  
paimon.fs.xxx
```

These parameters will be automatically converted and passed through. Here are some examples:

| Input Parameter | Converted Parameter for Paimon Java SDK |
|---|---|
| "paimon.s3.list.version" = "1" | "fs.s3a.list.version" = "1" |
| "paimon.s3.paging.maximum" = "100" | "fs.s3a.paging.maximum" = "100" |
| "paimon.fs.s3.read.ahead.buffer.size" = "1" | "fs.s3a.read.ahead.buffer.size" = "1" |
| "paimon.s3a.replication.factor" = "3" | "fs.s3a.replication.factor" = "3" |

- {CommonProperties}

The CommonProperties section is used to fill in common properties. Please refer to the [Catalog Overview](#) section on [Common Properties].

Supported Paimon Versions

The currently dependent Paimon version is 1.0.0.

Supported Paimon Formats

- Supports reading Paimon Deletion Vector

Supported Metadata Services

- [Hive Metastore](#)

- [Aliyun DLF](#)
- [FileSystem](#)

Note: The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

Supported Storage Systems

- [HDFS](#)
- [AWS S3](#)
- [Google Cloud Storage](#)
- [Alibaba Cloud OSS](#)
- [Tencent Cloud COS](#)
- [Huawei Cloud OBS](#)
- [MINIO](#)

Note: The service types and parameters supported by different Doris versions are slightly different. Please refer to the [Examples](#) section.

Supported Data Formats

- [Parquet](#)
- [ORC](#)

Column Type Mapping

| Paimon Type | Doris Type | Comment |
|-------------|------------|---------|
| boolean | boolean | |
| tinyint | tinyint | |
| smallint | smallint | |
| integer | int | |
| bigint | bigint | |
| float | float | |
| double | double | |

| Paimon Type | Doris Type | Comment |
|--------------------------------|------------------|---|
| decimal(P, S) | decimal(P, S) | |
| varchar | string | |
| char | string | |
| binary, varbinary | string/varbinary | Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is <code>false</code> , which maps to <code>string</code> ; when <code>true</code> , it maps to <code>varbinary</code> type. |
| date | date | |
| timestamp_without_time_zone | datetime(N) | Mapped according to precision. If precision is greater than 6, it maps to a maximum of 6 (may cause precision loss). |
| timestamp_with_local_time_zone | datetime(N) | Mapped according to precision. If precision is greater than 6, it maps to a maximum of 6 (may cause precision loss). |
| array | array | |
| map | map | |
| row | struct | |
| other | UNSUPPORTED | |

Note:

Doris currently does not support Timestamp types with timezone. All `timestamp_without_time_zone` and `timestamp_with_local_time_zone` will be uniformly mapped to `datetime(N)` type. However, during reading, Doris will correctly handle timezones based on the actual source type. For example, after specifying a timezone with `SET time_zone=<tz>`, it will affect the return results of `timestamp_with_local_time_zone` columns.

You can check whether the source type contains timezone information in the Extra column of the `DESCRIBE table_name` statement. If it displays `WITH_TIMEZONE`, it indicates that the source type is a timezone-aware type. (This feature is supported since 3.0.8)

Examples

Hive Metastore

Version 3.1+

HDFS

```
```sql
CREATE CATALOG test_paimon_on_hms_hdfs_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 'hdfs://127.0.0.1:8320/user/hive/warehouse',
```

```

'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
'fs.defaultFS' = 'hdfs://127.0.0.1:8320',
'hadoop.username' = 'doris'
);
...

```

## S3

```

```sql
CREATE CATALOG test_paimon_on_hms_aws_catalog PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
  'warehouse' = 's3://bucket/paimon_warehouse',
  's3.region' = 'ap-east-1',
  's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
  's3.access_key' = '<ak>',
  's3.secret_key' = '<sk>'
);
...

Obtaining S3 access credentials using an IAM Assumed Role (3.1.221+)
```sql
CREATE CATALOG paimon_hms_on_s3_iamrole PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 's3://bucket/warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.region' = 'us-east-1',
 's3.role_arn' = 'arn:aws:iam::543815668950:role/role'
);
...

```

## OSS

```

```sql
CREATE CATALOG test_paimon_on_hms_ali_catalog PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
  'warehouse' = 'oss://bucket/regression/paimon_warehouse',
  'oss.region' = 'cn-beijing',
  'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com',
  'oss.access_key' = '<ak>',
  'oss.secret_key' = '<sk>'
);
...

```

COS

```

```sql
CREATE CATALOG test_paimon_on_hms_tx_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 'cosn://bucket/paimon_warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',

```

```

 'cos.region' = 'ap-beijing',
 'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
 'cos.access_key' = '<ak>',
 'cos.secret_key' = '<sk>'
);
 ...

```

## OBS

```

```sql
CREATE CATALOG test_paimon_on_hms_hw_catalog PROPERTIES (
    'type' = 'paimon',
    'paimon.catalog.type' = 'hms',
    'warehouse' = 'obs://bucket/regression/paimon_warehouse',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'obs.region' = 'cn-north-4',
    'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
    'obs.access_key' = '<ak>',
    'obs.secret_key' = '<sk>'
);
...

```

GCS

```

```sql
CREATE CATALOG `paimon_on_gcs` PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 'gs://bucket/paimon_warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'fs.gcs.support' = 'true',
 'gs.secret_key' = '<sk>',
 'gs.access_key' = '<ak>'
);
...

```

## MinIO

```

```sql
CREATE CATALOG paimon_hms_on_minio_catalog PROPERTIES (
    'type' = 'paimon',
    'paimon.catalog.type' = 'hms',
    'warehouse' = 's3://test-bucket/paimon-warehouse',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'fs.minio.support' = 'true',
    'minio.endpoint' = 'http://127.0.0.1:19000',
    'minio.access_key' = 'minioadmin',
    'minio.secret_key' = 'minioadmin',
    'minio.use_path_style' = 'true'
);
...

```

HDFS

```

Access HMS without Kerberos authentication
```sql
CREATE CATALOG paimon_hms_on_hdfs_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 'warehouse' = 'hdfs://127.0.0.1:8320/user/paimon/warehouse/paimon-hms-hdfs-warehouse',
 'hadoop.username' = 'doris',
 'fs.defaultFS' = 'hdfs://127.0.0.1:8320'
);
```

Access HMS with Kerberos authentication enabled
```sql
CREATE CATALOG paimon_hms_on_hdfs_kerberos_hdfs_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 'hdfs://127.0.0.1:8520/paimon-hms-hdfs-warehouse',

'dlf.access_key' = '<ak>',
'dlf.secret_key' = '<sk>'
);
```

```

FileSystem Metastore

Version 3.1+

HDFS

```

Access HMS and HDFS services without Kerberos authentication
```sql
CREATE CATALOG ctl_test_paimon_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'filesystem',
 'warehouse' = 'hdfs://127.0.0.1:8020/user/doris/paimon1',
 'fs.defaultFS' = 'hdfs://127.0.0.1:8020'
);
```

```

S3

```

```sql
CREATE CATALOG test_paimon_on_fs_aws_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'filesystem',
 'warehouse' = 's3://bucket/paimon_warehouse',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```

Obtaining S3 access credentials using an IAM Assumed Role (3.1.2+)
```sql
CREATE CATALOG paimon_fs_on_s3_iamrole PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'filesystem',
 'warehouse' = 's3://bucket/warehouse',
 's3.region' = 'us-east-1',
 's3.role_arn' = 'arn:aws:iam::543815668950:role/role'
);
```

```

OSS

Use OSS

```

```sql
CREATE CATALOG paimon_base_filesystem_paimon_oss PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'filesystem',
 'warehouse' = 'oss://bucket/regression/paimon1',
 'oss.region'='cn-beijing',
 'oss.endpoint'='oss-cn-beijing.aliyuncs.com',
 'oss.access_key'='<ak>',
 'oss.secret_key'='<sk>'
);
```

Use OSS-HDFS

```sql
CREATE CATALOG paimon_base_filesystem_paimon_oss_hdfs PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'filesystem',
 'warehouse' = 'oss://bucket/regression/paimon1',
 'fs.oss-hdfs.support' = 'true',
 'oss.hdfs.access_key' = '<ak>',
 'oss.hdfs.secret_key' = '<sk>',
 'oss.hdfs.endpoint' = 'cn-beijing.oss-dls.aliyuncs.com',
 'oss.hdfs.region' = 'cn-beijing'
);
```

```

COS

```

```sql
CREATE CATALOG paimon_base_filesystem_paimon_coss PROPERTIES (

 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>'
);
```
```

```
```
```

## OSS

Use OSS

```
```sql
CREATE CATALOG paimon_base_filesystem_paimon_oss PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'filesystem',
  'warehouse' = 'oss://bucket/regression/paimon1',
  'oss.region'='cn-beijing',
  'oss.endpoint'='oss-cn-beijing.aliyuncs.com',
  'oss.access_key'='<ak>',
  'oss.secret_key'='<sk>'
);
```
```

Use OSS-HDFS

```
```sql
CREATE CATALOG paimon_base_filesystem_paimon_oss_hdfs PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'filesystem',
  'warehouse' = 'oss://bucket/regression/paimon1',
  'oss.hdfs.enabled' = 'true',
  'oss.access_key' = 'your-access-key',
  'oss.secret_key' = 'your-secret-key',
  'oss.endpoint' = 'cn-hangzhou.oss-dls.aliyuncs.com',
  'oss.region' = 'cn-hangzhou'
);
```
```

## COS

```
```sql
CREATE CATALOG paimon_base_filesystem_paimon_coss PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'filesystem',
  'warehouse' = 'cosn://bucket/regression/paimon1',
  'cos.region' = 'ap-beijing',
  'cos.endpoint' = 'cos.ap-beijing.myqcloud.com',
  'cos.access_key' = '<ak>',
  'cos.secret_key' = '<sk>'
);
```
```

## OBS

```
```sql
CREATE CATALOG paimon_base_filesystem_paimon_obs PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'filesystem',
  'warehouse' = 'obs://bucket/regression/paimon1',

```

```

        'obs.region' = 'cn-north-4',
        'obs.endpoint' = 'obs.cn-north-4.myhuaweicloud.com',
        'obs.access_key' = '<ak>',
        'obs.secret_key' = '<sk>'
    );
    ...

```

MinIO

```

```sql
CREATE CATALOG paimon_base_filesystem_paimon_minio PROPERTIES (
 'type' = 'paimon',
 'warehouse' = 's3://warehouse/wh',
 'paimon.catalog.type' = 'filesystem',
 's3.endpoint' = 'http://127.0.0.1:19001',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>',
 's3.path.style.access' = 'true'
);
...

```

## Query Operations

### Basic Query

Once the Catalog is configured, you can query the table data in the Catalog as follows:

```

-- 1. Switch to catalog, use database, and query
SWITCH paimon_ctl;
USE paimon_db;
SELECT * FROM paimon_tbl LIMIT 10;

-- 2. Use Paimon database directly
USE paimon_ctl.paimon_db;
SELECT * FROM paimon_tbl LIMIT 10;

-- 3. Use fully qualified name to query
SELECT * FROM paimon_ctl.paimon_db.paimon_tbl LIMIT 10;

```

### Batch Incremental Query

Since version 3.1.0

Supports [Batch Incremental](#) queries for Paimon, similar to Flink.

Supports querying incremental data within specified snapshot or timestamp intervals. The interval is left-closed and right-open.

```

-- between snapshots [0, 5)
SELECT * FROM paimon_table@incr('startSnapshotId'='0', 'endSnapshotId'='5');

```

```

-- between snapshots [0, 5) with specified scan mode
SELECT * FROM paimon_table@incr('startSnapshotId'='0', 'endSnapshotId'='5',
'incrementalBetweenScanMode'='diff');

-- read from start timestamp
SELECT * FROM paimon_table@incr('startTimestamp'='1750844949000');

-- read between timestamp
SELECT * FROM paimon_table@incr('startTimestamp'='1750844949000', 'endTimestamp'='1750944949000');

```

Parameter:

Parameter	Description	Example
startSnapshotId	Starting snapshot ID, must be greater than 0. Must be specified with endSnapshotId together.	'startSnapshotId'='3'
endSnapshotId	Ending snapshot ID, must be greater than startSnapshotId. Must be specified with startSnapshotId together.	'endSnapshotId'='10'
incrementalBetweenScanMode	Specifies the incremental read mode, default is auto, supports delta, changelog and diff	'incrementalBetweenScanMode'='delta'
startTimestamp	Starting snapshot timestamp, must be greater than or equal to 0. Unit is millisecond.	'startTimestamp'='1750844949000'
endTimestamp	Ending snapshot timestamp, must be greater than startTimestamp. Optional, if not specified, reads from startTimestamp to the latest snapshot. Unit is millisecond.	'endTimestamp'='1750944949000'

Notice:

startSnapshotId and endSnapshotId will compose the Paimon parameter 'incremental-between'='3,10'

startTimestamp and endTimestamp will compose the Paimon parameter 'incremental-between-timestamp'='1750844949000,1750944949000'

incrementalBetweenScanMode corresponds to the Paimon parameter incremental-between-scan-mode.

Refer to the [Paimon documentation](#) for further details about these parameters.

## Time Travel

Since version 3.1.0

Supports reading specified snapshots of Paimon tables.

By default, read requests only read the latest version of snapshots.

You can query snapshots of a specified Paimon table through the \$snapshots table function:

```
Doris > SELECT snapshot_id,commit_time FROM paimon_tbl$snapshots;
+-----+-----+
| snapshot_id | commit_time |
+-----+-----+
| 1 | 2025-08-17 06:05:52.740 |
| 2 | 2025-08-17 06:05:52.979 |
| 3 | 2025-08-17 06:05:53.240 |
| 4 | 2025-08-17 06:05:53.561 |
+-----+-----+
```

You can use FOR TIME AS OF and FOR VERSION AS OF statements to read historical version data based on snapshot ID or the time when the snapshot was created. Examples:

```
-- Notice:
-- Before 3.1.1, only support format like YYYY-MM-DD HH:MM:SS.SSS
-- After 3.1.2, support YYYY-MM-DD HH:MM:SS and YYYY-MM-DD
SELECT * FROM paimon_tbl FOR TIME AS OF "2025-08-17 06:05:52.740";
SELECT * FROM paimon_tbl FOR TIME AS OF "2025-08-17 06:05:52";
SELECT * FROM paimon_tbl FOR TIME AS OF "2025-08-17";

-- Notice: The timestamp must be precise down to the millisecond.
SELECT * FROM paimon_tbl FOR TIME AS OF 1755381952740;
-- Use snapshot id
SELECT * FROM paimon_tbl FOR VERSION AS OF 1;
```

## Branch and Tag

Since version 3.1.0

Supports reading branches and tags of specified Paimon tables.

You can use the \$branches and \$tags system tables to view branches and tags of Paimon tables:

```
Doris > SELECT * FROM paimon_tbl$branches;
+-----+-----+
| branch_name | create_time |
+-----+-----+
| b_1 | 2025-08-17 06:34:37.294 |
| b_2 | 2025-08-17 06:34:37.297 |
+-----+-----+

Doris > SELECT * FROM paimon_tbl$tags;
+-----+-----+-----+-----+-----+-----+-----+
| tag_name | snapshot_id | schema_id | commit_time | record_count | create_time | time_retained |
+-----+-----+-----+-----+-----+-----+-----+
| t_1 | 1 | 0 | 2025-08-17 06:05:52.740 | 3 | NULL | NULL |
| t_2 | 2 | 0 | 2025-08-17 06:05:52.979 | 6 | NULL | NULL |
| t_3 | 3 | 0 | 2025-08-17 06:05:53.240 | 9 | NULL | NULL |
| t_4 | 4 | 0 | 2025-08-17 06:05:53.561 | 12 | NULL | NULL |
+-----+-----+-----+-----+-----+-----+-----+
```

Supports various syntax forms to be compatible with systems like Spark/Trino:

```

-- BRANCH
SELECT * FROM paimon_tbl@branch(branch1);
SELECT * FROM paimon_tbl@branch("name" = "branch1");

-- TAG
SELECT * FROM paimon_tbl@tag(tag1);
SELECT * FROM paimon_tbl@tag("name" = "tag1");
SELECT * FROM paimon_tbl FOR VERSION AS OF 'tag1';

```

For the `FOR VERSION AS OF` syntax, Doris will automatically determine whether the parameter is a timestamp

## System Tables

Since version 3.1.0

Doris supports querying Paimon system tables to retrieve table-related metadata. System tables can be used to view snapshot history, manifest files, data files, partitions, and other information.

To access metadata of a Paimon table, add a `$` symbol after the table name, followed by the system table name:

```
SELECT * FROM my_table$system_table_name;
```

Note: Doris does not support reading Paimon global system tables, which are only supported in Flink.

### schemas

Shows current and historical schema information of the table. When modifying table schema using `ALTER TABLE`, `CREATE TABLE AS`, or `CREATE DATABASE AS` statements, each modification generates a record in the schemas table:

```
SELECT * FROM my_table$schemas;
```

Result:

```

+-----+-----+-----+-----+-----+-----+
| schema_id | fields
| partition_keys | primary_keys | options | comment | update_time |
+-----+-----+-----+-----+-----+-----+
| 0 | [{"id":0,"name":"k","type":"INT NOT NULL"}, {"id":1,"name":"f0","type":"INT"},
{"id":2,"name":"f1","type":"STRING"}] | [] | [{"k"}] | {} | | 2025-03-04
22:48:41.666 |
+-----+-----+-----+-----+-----+-----+

```

## snapshots

Shows all valid snapshot information of the table, including snapshot creation time, commit user, operation type, etc.:

```
SELECT * FROM my_table$snapshots;
```

Result:

```
+-----+-----+-----+-----+-----+-----+
| snapshot_id | schema_id | commit_user | commit_identif | commit_kind |
| commit_time | base_manifest_list | delta_manifest_list |
| changelog_manifest_list | total_record_count | delta_record_count | changelog_record_count | watermark |
|-----+-----+-----+-----+-----+-----+
| 1 | 0 | d7ea4996-92c7-469f-b9ff-c76525954f1c | 9223372036854775807 | APPEND | 2025-

+-----+-----+-----+-----+-----+-----+
```

## options

Shows current configuration options of the table. If a table option is not included in the table, that option is set to its default value:

```
SELECT * FROM my_table$options;
```

Result:

key	value
snapshot.time-retained	5 h

files

Shows information about all data files pointed to by the current snapshot, including file format, record count, file size, etc.:

```
SELECT * FROM my_table$files;
```

Result:

```
mysql> SELECT * FROM my_table$files;
```

partition	bucket	file_path	file_format	schema_id	level	record_count	file_size_in_bytes	min_key	max_key	null_value_counts	min_value_stats	max_value_stats	min_sequence_number	max_sequence_number	creation_time	file_source
{}	0	s3://paimon-warehouse-dev/test-flink/cookbook.db/my_table/bucket-0/data-b4a49c57-6ef6-4c04-8813-07a4960d987c-0.parquet	parquet			0	5		5	1321	[1]					
[6]		{f0=0, f1=0, k=0}   {f0=4, f1=111, k=1}   {f0=11, f1=k7, k=6}								0						
5		2025-07-01 23:14:23.967	COMPACT													

tags

Shows all tag information of the table, including tag names and associated snapshots:

```
SELECT * FROM my_table$tags;
```

Result:

tag_name	snapshot_id	schema_id	commit_time	record_count	branches
tag1	1	0	2025-03-04 14:55:29.344	3	[]
tag3	3	0	2025-03-04 14:58:24.691	7	[branch-1]

### branches

Shows all known branch information of the table:

```
SELECT * FROM my_table$branches;
```

Result:

branch_name	create_time
branch1	2025-03-04 20:31:39.084
branch2	2025-03-04 21:11:14.373

### consumers

Shows consumer information of the table, used to track data consumption:

```
SELECT * FROM my_table$consumers;
```

Result:

consumer_id	next_snapshot_id
id1	1
id2	3

### manifests

Shows manifest file information of the table's current snapshot:

```
SELECT * FROM my_table$manifests;
```

Result:

file_name	file_size	num_added_files	num_deleted_files
schema_id   min_partition_stats   max_partition_stats			
manifest-3df9bb64-5c11-4aef-994e-d8717fedfc70-0   {}	1949	1	0
manifest-d7eb4ec4-7238-478a-9ae6-91a4cceb561-0   {}	1946	1	0
manifest-3b6f4079-c893-4413-aedc-1e8fbcea6db1-0   {}	1948	1	0
manifest-abe5177f-82da-4e86-9864-40efffb391bd-0   {}	1964	1	0
manifest-ee89dff3-a523-4655-a4b8-d7c9e471a1d6-0	1949	1	0

## statistics

Shows statistical information of the table, including row count, data size, and other statistics:

```
SELECT * FROM my_table$statistics;
```

Result:

snapshot_id	schema_id	mergedRecordCount	mergedRecordSize	colstat
2	0	2	2	{}

## table\_indexes

Shows index information of the table:

```
SELECT * FROM my_table$table_indexes;
```

Result:

file_name	partition	bucket	row_count	index_type	dv_ranges
9f...	{2025-03-01}	0	3	HASH	index-70abfebf-149e-4796-9f...<NULL>
87...	{2025-04-01}	0	1	DELETION_VECTORS	index-633857e7-cdce-47d2-87...[(data-346cb9c8-4032-4d66-a...

## System Table Use Cases

Through system tables, you can easily accomplish the following operations and monitoring tasks.

### View the latest snapshot information of a table to understand its current state

```
SELECT snapshot_id, commit_time, commit_kind, total_record_count FROM catalog_sales$snapshots ORDER BY snapshot_id DESC;
```

Result:

snapshot_id	commit_time	commit_kind	total_record_count
-------------	-------------	-------------	--------------------

View table information for snapshots

```
SELECT s.snapshot_id, t.schema_id, t.fields FROM store_sales$snapshots s JOIN store_sales$schemas t ON s.schema_id=t.schema_id;
```

Result:

snapshot_id	schema_id	fields
1	0	[{"id":0,"name":"ss_sold_date_sk","type":"INT"}, {"id":1,"name":"ss_item_sk","type":"INT NOT NULL"}, {"id":2,"name":"ss_ticket_number","type":"INT NOT NULL"}, {"id":3,"name":"ss_sold_time_sk","type":"INT"}, {"id":4,"name":"ss_customer_sk","type":"INT"}, {"id":5,"name":"ss_cdemo_sk","type":"INT"}, {"id":6,"name":"ss_hdemo_sk","type":"INT"}, {"id":7,"name":"ss_addr_sk","type":"INT"}, {"id":8,"name":"ss_store_sk","type":"INT"}, {"id":9,"name":"ss_promo_sk","type":"INT"}, {"id":10,"name":"ss_quantity","type":"INT"}, {"id":11,"name":"ss_wholesale_cost","type":"DECIMAL(7, 2)"}, {"id":12,"name":"ss_list_price","type":"DECIMAL(7, 2)"}, {"id":13,"name":"ss_sales_price","type":"DECIMAL(7, 2)"}, {"id":14,"name":"ss_ext_discount_amt","type":"DECIMAL(7, 2)"}, {"id":15,"name":"ss_ext_sales_price","type":"DECIMAL(7, 2)"}, {"id":16,"name":"ss_ext_wholesale_cost","type":"DECIMAL(7, 2)"}, {"id":17,"name":"ss_ext_list_price","type":"DECIMAL(7, 2)"}, {"id":18,"name":"ss_ext_tax","type":"DECIMAL(7, 2)"}, {"id":19,"name":"ss_coupon_amt","type":"DECIMAL(7, 2)"}, {"id":20,"name":"ss_net_paid","type":"DECIMAL(7, 2)"}, {"id":21,"name":"ss_net_paid_inc_tax","type":"DECIMAL(7, 2)"}, {"id":22,"name":"ss_net_profit","type":"DECIMAL(7, 2)"}]
2	0	[{"id":0,"name":"ss_sold_date_sk","type":"INT"}, {"id":1,"name":"ss_item_sk","type":"INT NOT NULL"}, {"id":2,"name":"ss_ticket_number","type":"INT NOT NULL"}, {"id":3,"name":"ss_sold_time_sk","type":"INT"}, {"id":4,"name":"ss_customer_sk","type":"INT"}, {"id":5,"name":"ss_cdemo_sk","type":"INT"}, {"id":6,"name":"ss_hdemo_sk","type":"INT"}, {"id":7,"name":"ss_addr_sk","type":"INT"}, {"id":8,"name":"ss_store_sk","type":"INT"}, {"id":9,"name":"ss_promo_sk","type":"INT"}, {"id":10,"name":"ss_quantity","type":"INT"}, {"id":11,"name":"ss_wholesale_cost","type":"DECIMAL(7, 2)"}, {"id":12,"name":"ss_list_price","type":"DECIMAL(7, 2)"}, {"id":13,"name":"ss_sales_price","type":"DECIMAL(7, 2)"}, {"id":14,"name":"ss_ext_discount_amt","type":"DECIMAL(7, 2)"}]

[illegible]

```
java.io.UncheckedIOException: org.apache.paimon.fs.UnsupportedSchemeException: Could not find a file
io implementation for scheme 's3a' in the classpath. Hadoop FileSystem also cannot access this path
's3a://`.
```

**Versions prior to 3.1** Versions prior to 3.1 do not support the s3a protocol. If you must use it, you can temporarily add the s3a-related parameters as a workaround.

**Version 3.1 and above** Starting from version 3.1, explicitly adding s3a parameters is no longer necessary. If you need to override Paimon storage parameters, you can add parameters with the `paimon.fs.` prefix. Since Paimon internally uses the HDFS API, all `fs.s3a.*` parameters are supported.

For example:

```
CREATE CATALOG `paimon_hms_on_s3a` PROPERTIES (
 "type" = "paimon",
 "paimon.catalog.type" = "hms",
 "hive.metastore.uris" = "thrift://172.20.48.119:9383"
 "warehouse" = "s3a://bucket/paimon_warehouse",
 "s3.access_key" = "<ak>",
 "s3.secret_key" = "<sk>",
 "s3.region" = "ap-east-1",
 "s3.endpoint" = "https://s3.ap-east-1.amazonaws.com",
 -- explicitly add s3a parameters
 "fs.s3a.access.key" = "<ak>",
 "fs.s3a.secret.key" = "<sk>",
 "fs.s3a.endpoint.region" = "ap-east-1",
 "fs.s3a.endpoint" = "https://s3.ap-east-1.amazonaws.com",
 "fs.s3a.impl" = "org.apache.hadoop.fs.s3a.S3AFileSystem",
);
```

When using the s3 protocol, you need to explicitly add Paimon S3-related parameters, i.e., add the `paimon.s3.` prefix. For example:

```
CREATE CATALOG test_paimon_on_hms_aws_catalog PROPERTIES (
 'type' = 'paimon',
 'paimon.catalog.type' = 'hms',
 'warehouse' = 's3://bucket-hk/paimon_warehouse',
 'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
 's3.region' = 'ap-east-1',
 's3.endpoint' = 'https://s3.ap-east-1.amazonaws.com',
 's3.access_key' = '<ak>',
 's3.secret_key' = '<sk>',
 -- explicitly add s3a parameters
 'paimon.s3.region' = 'ap-east-1',
 'paimon.s3.endpoint' = 'ap-east-1',
 'paimon.s3.access-key' = '<ak>',
 'paimon.s3.secret-key' = '<sk>'
);
```

# MaxCompute Catalog

[MaxCompute](#) is an enterprise-level SaaS (Software as a Service) cloud data warehouse on Alibaba Cloud. Through the open storage SDK provided by MaxCompute, Doris can access MaxCompute table information and perform queries.

## Applicable Scenarios

Scenario	Description
Data Integration	Read MaxCompute data and write it to Doris internal tables.
Data Write-back	Not supported.

## Notes

- Starting from version 2.1.7, the MaxCompute Catalog is developed based on the [open storage SDK](#). Before this, it was developed based on the Tunnel API.
- There are certain restrictions on the use of the open storage SDK. Please refer to the Usage Restrictions section in this [document](#).
- Before Doris version 3.1.3, a Project in MaxCompute is equivalent to a Database in Doris. After 3.1.3, You can use the `mc.enable.namespace.schema` parameter to introduce the MaxCompute schema level.

## Configuring Catalog

### Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (
 'type' = 'max_compute',
 {McRequiredProperties},
 {McOptionalProperties},
 {CommonProperties}
);
```

- {McRequiredProperties}

Property Name	Description	Supported Doris Version
<code>mc.default.project</code>	The name of the MaxCompute project you want to access. You can create and manage it in the <a href="#">MaxCompute Project List</a> .	

Property Name	Description	Supported Doris Version
mc.access_key	AccessKey. You can create and manage it in the <a href="#">Alibaba Cloud Console</a> .	
mc.secret_key	SecretKey. You can create and manage it in the <a href="#">Alibaba Cloud Console</a> .	
mc.region	The region where MaxCompute is enabled. You can find the corresponding region from the Endpoint.	Before 2.1.7
mc.endpoint	The region where MaxCompute is enabled. Please refer to the section below on how to obtain Endpoint and Quota for configuration.	2.1.7 and later

- {McOptionalProperties}

Property Name	Default Value	Description	Supported Doris Version
mc.tunnel_endpoint	None	Refer to the appendix on Custom Service Address.	Before 2.1.7
mc.odps_endpoint	None	Refer to the appendix on Custom Service Address.	Before 2.1.7
mc.quota	pay-as-you-go	Quota name. Please refer to the section on how to obtain Endpoint and Quota for configuration.	2.1.7 and later
mc.split_strategy	byte_size	Sets the split strategy. Can be set to byte_size (split by byte size) or row_count (split by number of rows).	2.1.7 and later
mc.split_byte_size	268435456	The file size (in bytes) read by each split. Default is 256 MB. Effective only when "mc.split_strategy" = "byte_size".	2.1.7 and later
mc.split_row_count	1048576	The number of rows read by each split. Effective only when "mc.split_strategy" = "row_count".	2.1.7 and later
mc.split_cross_partition	false	Whether the generated split crosses partitions.	2.1.8 and later
mc.connect_timeout	10s	Timeout for connecting to MaxCompute.	2.1.8 and later
mc.read_timeout	120s	Timeout for reading from MaxCompute.	2.1.8 and later
mc.retry_count	4	Number of retries after a timeout.	2.1.8 and later
mc.datetime_predicate_push_down	true	Whether to allow pushdown of predicate conditions of timestamp/timestamp_ntz types. Doris will lose precision (9 -> 6) when synchronizing these two types. Therefore, if the original data has a precision higher than 6 digits, condition pushdown may lead to inaccurate results.	2.1.9/3.0.5 and later
mc.account_format	name	The account systems of Alibaba Cloud International and China are different. For users of the International site, if an error such as user 'RAM\$xxxxxx:xxxxx' is not a valid aliyun account occurs, you can specify this parameter as id.	3.0.9/3.1.1 later
mc.enable_namespace.schema	false	Whether MaxCompute's schema level is supported. For details, see: <a href="https://help.aliyun.com/zh/maxcompute/user-guide/schema-related-operations">https://help.aliyun.com/zh/maxcompute/user-guide/schema-related-operations</a>	3.1.3 and later

- [CommonProperties]

The CommonProperties section is used to fill in common properties. Please refer to the Catalog Overview section on [Common Properties](#).

## Supported MaxCompute Versions

Only the public cloud version of MaxCompute is supported. For support with the private cloud version, please contact the Doris community.

## Supported MaxCompute Formats

- Supports reading partitioned tables, clustered tables, and materialized views.
- Does not support reading MaxCompute external tables, logical views, or Delta Tables.

## Hierarchical Mapping

- mc.enable.namespace.schema is false

Doris	MaxCompute
Catalog	N/A
Database	Project
Table	Table

- mc.enable.namespace.schema is true

Doris	MaxCompute
Catalog	Project
Database	Schema
Table	Table

## Column Type Mapping

MaxCompute Type	Doris Type	Comment
boolean	boolean	
tiny	tinyint	
tinyint	tinyint	
smallint	smallint	
int	int	
bigint	bigint	
float	float	

MaxCompute Type	Doris Type	Comment
double	double	
decimal(P, S)	decimal(P, S)	1 <= P <= 38 ,0 <= scale <= 18
char(N)	char(N)	
varchar(N)	varchar(N)	
string	string	
date	date	
datetime	datetime(3)	Fixed mapping to precision 3. You can specify the time zone using SET [GLOBAL] time_zone = 'Asia/Shanghai'.
timestamp_ntz	datetime(6)	The precision of MaxCompute's timestamp_ntz is 9, but Doris' DATETIME supports a maximum precision of 6. Therefore, the extra part will be directly truncated when reading data.
timestamp	datetime(6)	Since 2.1.9 & 3.0.5. The precision of MaxCompute's timestamp is 9, but Doris' DATETIME supports a maximum precision of 6. Therefore, the extra part will be directly truncated when reading data.
array	array	
map	map	
struct	struct	
other	UNSUPPORTED	

## Examples

```
CREATE CATALOG mc_catalog PROPERTIES (
 'type' = 'max_compute',
 'mc.default.project' = 'project',
 'mc.access_key' = 'sk',
 'mc.secret_key' = 'ak',
 'mc.endpoint' = 'http://service.cn-beijing-vpc.MaxCompute.aliyun-inc.com/api'
);
```

If you are using a version earlier than 2.1.7 (exclusive), please use the following statements. (It is recommended to upgrade to 2.1.8 or later for usage)

```
CREATE CATALOG mc_catalog PROPERTIES (
 'type' = 'max_compute',
 'mc.region' = 'cn-beijing',
 'mc.default.project' = 'project',
 'mc.access_key' = 'ak',
 'mc.secret_key' = 'sk'
 'mc.odps_endpoint' = 'http://service.cn-beijing.maxcompute.aliyun-inc.com/api',
 'mc.tunnel_endpoint' = 'http://dt.cn-beijing.maxcompute.aliyun-inc.com'
);
```

Support Schema:

```
CREATE CATALOG mc_catalog PROPERTIES (
 'type' = 'max_compute',
 'mc.region' = 'cn-beijing',
 'mc.default.project' = 'project',
 'mc.access_key' = 'ak',
 'mc.secret_key' = 'sk'
 'mc.odps_endpoint' = 'http://service.cn-beijing.maxcompute.aliyun-inc.com/api',
 'mc.tunnel_endpoint' = 'http://dt.cn-beijing.maxcompute.aliyun-inc.com',
 'mc.enable.namespace.schema' = 'true'
);
```

## Query Operations

### Basic Query

```
-- 1. Switch to catalog, use database, and query
SWITCH mc_ctl;
USE mc_ctl;
SELECT * FROM mc_tbl LIMIT 10;

-- 2. Use mc database directly
USE mc_ctl.mc_db;
SELECT * FROM mc_tbl LIMIT 10;

-- 3. Use fully qualified name to query
SELECT * FROM mc_ctl.mc_db.mc_tbl LIMIT 10;
```

## Appendix

### How to Obtain Endpoint and Quota (For Doris 2.1.7 and Later)

#### 1. If using a dedicated resource group for Data Transmission Service (DTS)

Refer to the [documentation](#) under the section “**Use Dedicated Data Service Resource Groups**”, specifically “**2. Authorization**”, to enable the required permissions. Then, navigate to the “**Quota Management**” list to view and copy the corresponding QuotaName, and specify it using "mc.quota" = "QuotaName". At this point, you can choose to access MaxCompute via VPC or public network. However, VPC provides guaranteed bandwidth, while public network bandwidth is limited.

#### 2. If using pay-as-you-go

Refer to the [documentation](#) under the section “**Using Open Storage (Pay-As-You-Go)**” to enable the Open Storage (Storage API) switch and grant permissions to the user corresponding to the Ak and SK. In this case, mc.quota defaults to pay-as-you-go, and no additional value needs to be specified. When using the pay-as-you-go model, MaxCompute can only be accessed via VPC, and public network access is not available. Only prepaid users can access MaxCompute via the public network.

#### 3. Configure mc.endpoint based on the [Alibaba Cloud Endpoints Documentation](#)

For users accessing via VPC, refer to the “**VPC Network Endpoint**” column in the “**Regional Endpoint Table (Alibaba Cloud VPC Network Connection Method)**” to configure mc.endpoint.

For users accessing via the public network, you can choose from the “**Classic Network Endpoint**” column in the “**Regional Endpoint Table (Alibaba Cloud Classic Network Connection Method)**”, or the “**External Network Endpoint**” column in the “**Regional Endpoint Table (External Network Connection Method)**” to configure `mc.endpoint`.

## Custom Service Address (For Doris Versions before 2.1.7)

In Doris versions before 2.1.7, the **Tunnel SDK** is used to interact with MaxCompute. Therefore, the following two endpoint properties need to be configured:

- `mc.odps_endpoint`: MaxCompute Endpoint, used to retrieve MaxCompute metadata (e.g., database and table information).
- `mc.tunnel_endpoint`: Tunnel Endpoint, used to read MaxCompute data.

By default, the MaxCompute Catalog generates endpoints based on the values of `mc.region` and `mc.public_access`.

The generated endpoint formats are as follows:

<code>mc.public_access</code>	<code>mc.odps_endpoint</code>	<code>mc.tunnel_endpoint</code>
false	<code>http://service.{mc.region}.maxcompute.aliyun-inc.com/api</code>	<code>http://dt.{mc.region}.maxcompute.aliyun-inc.com</code>
true	<code>http://service.{mc.region}.maxcompute.aliyun.com/api</code>	<code>http://dt.{mc.region}.maxcompute.aliyun.com</code>

Users can also manually specify `mc.odps_endpoint` and `mc.tunnel_endpoint` to customize the service addresses. This is particularly useful for private deployments of MaxCompute environments.

For details on configuring MaxCompute Endpoint and Tunnel Endpoint, refer to the documentation on [Endpoints for Different Regions and Network Connection Methods](#).

## Resource Usage Control

Users can adjust the `parallel_pipeline_task_num` and `num_scanner_threads` session variables to control the [table-level request concurrency](#) and manage resource consumption in the data transmission service. The corresponding concurrency equals  $\max(\text{parallel\_pipeline\_task\_num} * \text{be\_num} * \text{num\_scanner\_threads})$ .

Note:

1. This method can only control the concurrent request count for a single table in a single query, and cannot control resource usage across multiple SQL statements.
2. Reducing the concurrency will increase the query time.

# Delta Lake Catalog

Delta Lake Catalog uses the [Trino Connector](#) compatibility framework to access Delta Lake tables through the Delta Lake Connector.

This feature is experimental and has been supported since version 3.0.1.

## Application Scenarios

Scenario	Description
Data Integration	Read Delta Lake data and write it into Doris internal tables.
Data Writeback	Not supported.

## Environment Preparation

### Compile the Delta Lake Connector Plugin

JDK 17 is required.

```
$ git clone https://github.com/apache/doris-thirdparty.git
$ cd doris-thirdparty
$ git checkout trino-435
$ cd plugin/trino-delta-lake
$ mvn clean install -DskipTests
$ cd ../../lib/trino-hdfs
$ mvn clean install -DskipTests
```

After compiling, you will find the `trino-delta-lake-435` directory under `trino/plugin/trino-delta-lake/target/` and the `hdfs` directory under `trino/lib/trino-hdfs/target/`.

You can also directly download the precompiled [trino-delta-lake-435-20240724.tar.gz](#) and [hdfs.tar.gz](#), then extract them.

### Deploy the Delta Lake Connector

Place the `trino-delta-lake-435/` directory in the `connectors/` directory of all FE and BE deployment paths(If it does not exist, you can create it manually) and extract `hdfs.tar.gz` into the `trino-delta-lake-435/` directory.

```
|— bin
|— conf
|— connectors
```

After deployment, it is recommended to restart the FE and BE nodes to ensure the Connector is loaded correctly.

## Configuring Catalog

### Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name
PROPERTIES (
 'type' = 'trino-connector', -- required
 'trino.connector.name' = 'delta_lake', -- required
 {TrinoProperties},
 {CommonProperties}
);
```

- {TrinoProperties}

The TrinoProperties section is used to specify properties that will be passed to the Trino Connector. These properties use the `trino.` prefix. In theory, all properties supported by Trino are also supported here. For more information about Delta Lake, refer to the [Trino documentation](#).

- [CommonProperties]

The CommonProperties section is used to specify general properties. Please refer to the [Catalog Overview](#) under the “Common Properties” section.

### Supported Delta Lake Versions

For more information about Delta Lake, refer to the [Trino documentation](#).

### Supported Metadata Services

For more information about Delta Lake, refer to the [Trino documentation](#).

### Supported Storage Systems

For more information about Delta Lake, refer to the [Trino documentation](#).

## Column Type Mapping

Delta Lake Type	Trino Type	Doris Type	Comment
boolean	boolean	boolean	
int	int	int	
byte	tinyint	tinyint	

Delta Lake Type	Trino Type	Doris Type	Comment
short	smallint	smallint	
long	bigint	bigint	
float	real	float	
double	double	double	
decimal(P, S)	decimal(P, S)	decimal(P, S)	
string	varchar	string	
binary	varbinary	string	
date	date	date	
timestamp_ntz	timestamp(N)	datetime(N)	
timestamp	timestamp with time zone(N)	datetime(N)	
array	array	array	
map	map	map	
struct	row	struct	

## Examples

```
CREATE CATALOG delta_lake_hms properties (
 'type' = 'trino-connector',
 'trino.connector.name' = 'delta_lake',
 'trino.hive.metastore' = 'thrift',
 'trino.hive.metastore.uri' = 'thrift://ip:port',
 'trino.hive.config.resources' = '/path/to/core-site.xml,/path/to/hdfs-site.xml'
);
```

## Query Operations

After configuring the Catalog, you can query the table data in the Catalog using the following methods:

```
-- 1. Switch to the catalog, use the database, and query
SWITCH delta_lake_ctl;
USE delta_lake_db;
SELECT * FROM delta_lake_tbl LIMIT 10;

-- 2. Use the Delta Lake database directly
USE delta_lake_ctl.delta_lake_db;
SELECT * FROM delta_lake_tbl LIMIT 10;

-- 3. Use the fully qualified name to query
SELECT * FROM delta_lake_ctl.delta_lake_db.delta_lake_tbl LIMIT 10;
```

# BigQuery Catalog

BigQuery Catalog uses the [Trino Connector](#) compatibility framework to access BigQuery tables through the BigQuery Connector.

This feature is experimental and has been supported since version 3.0.1.

## Application Scenarios

Scenario	Description
Data Integration	Read BigQuery data and write it into Doris internal tables.
Data Writeback	Not supported.

## Environment Preparation

### Compile the BigQuery Connector Plugin

JDK 17 is required.

```
$ git clone https://github.com/apache/doris-thirdparty.git
$ cd doris-thirdparty
$ git checkout trino-435
$ cd plugin/trino-bigquery
$ mvn clean install -DskipTests
```

After compilation, the `trino/plugin/trino-bigquery/target/` directory will contain the `trino-bigquery-435` folder.

You can also directly download the precompiled [trino-bigquery-435-20240724.tar.gz](#) and extract it.

### Deploy the BigQuery Connector

Place the `trino-bigquery-435/` directory into the `connectors/` directory of the deployment paths for all FE and BE nodes. (If the directory does not exist, you can create it manually.)

```
| bin
| conf
| connectors
| | trino-bigquery-435
...

```

After deployment, it is recommended to restart the FE and BE nodes to ensure the Connector is loaded correctly.

## Configuring Catalog

### Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name
PROPERTIES (
 'type' = 'trino-connector', -- required
 'trino.connector.name' = 'bigquery', -- required
 {TrinoProperties},
 {CommonProperties}
);
```

- {TrinoProperties}

The TrinoProperties section is used to specify properties that will be passed to the Trino Connector. These properties use the `trino.` prefix. In theory, all properties supported by Trino are also supported here. For more information about BigQuery, refer to the [Trino documentation](#).

- [CommonProperties]

The CommonProperties section is used to specify general properties. Please refer to the [Catalog Overview](#) under the “Common Properties” section.

### Supported BigQuery Versions

For more information about BigQuery properties, refer to the [Trino documentation](#).

### Column Type Mapping

BigQuery Type	Trino Type	Doris Type
boolean	boolean	boolean
int64	bigint	bigint
float64	double	double
numeric	decimal(P, S)	decimal(P, S)
bignumeric	decimal(P, S)	decimal(P, S)
string	varchar	string
bytes	varbinary	string
date	date	date
datetime	timestamp(6)	datetime(6)
time	time(6)	string
timestamp	timestamp with time zone(6)	datetime(6)

BigQuery Type	Trino Type	Doris Type
geography	varchar	string
array	array	array
map	map	map
struct	row	struct

## Examples

```
CREATE CATALOG bigquery_catalog PROPERTIES (
 'type' = 'trino-connector',
 'trino.connector.name' = 'bigquery',
 'trino.bigquery.project-id' = 'your-bigquery-project-id',
 'trino.bigquery.credentials-file' = '/path/to/application_default_credentials.json',
);
```

## Query Operations

After configuring the Catalog, you can query the table data in the Catalog using the following methods:

```
-- 1. switch to catalog, use database and query
SWITCH bigquery_ctl;
USE bigquery_db;
SELECT * FROM bigquery_tbl LIMIT 10;

-- 2. use bigquery database directly
USE bigquery_ctl.bigquery_db;
SELECT * FROM bigquery_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM bigquery_ctl.bigquery_db.bigquery_tbl LIMIT 10;
```

# Kudu Catalog

Kudu Catalog uses the [Trino Connector](#) compatibility framework to access Kudu tables through the Kudu Connector.

This feature is experimental and has been supported since version 3.0.1.

## Application Scenarios

Scenario	Description
Data Integration	Read Kudu data and write it into Doris internal tables.
Data Writeback	Not supported.

## Environment Preparation

### Compile the Kudu Connector Plugin

JDK 17 is required.

```
$ git clone https://github.com/apache/doris-thirdparty.git
$ cd doris-thirdparty
$ git checkout trino-435
$ cd plugin/trino-kudu
$ mvn clean package -Dmaven.test.skip=true
```

After compilation, the `trino/plugin/trino-kudu/target/` directory will contain the `trino-kudu-435` folder.

You can also directly download the precompiled [trino-kudu-435-20240724.tar.gz](#) and extract it.

### Deploy the Kudu Connector

Place the `trino-kudu-435/` directory into the `connectors/` directory of the deployment paths for all FE and BE nodes. (If the directory does not exist, you can create it manually.)

```
|— bin
|— conf
|— connectors
| |— trino-kudu-435
...

```

After deployment, it is recommended to restart the FE and BE nodes to ensure the Connector is loaded correctly.

# Configuring Catalog

## Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (
 'type' = 'trino-connector', -- required
 'trino.connector.name' = 'kudu', -- required
 {TrinoProperties},
 {CommonProperties}
);
```

- {TrinoProperties}

The `TrinoProperties` section is used to specify properties that will be passed to the Trino Connector. These properties are prefixed with `trino..` In theory, all properties supported by Trino are also supported here. For more information about Kudu properties, refer to the [Trino documentation](#).

- [CommonProperties]

The `CommonProperties` section is used to specify general properties. Please refer to the [Catalog Overview](#) under the “Common Properties” section.

## Supported Kudu Versions

For more information about Kudu, refer to the [Trino documentation](#).

## Supported Metadata Services

For more information about Kudu, refer to the [Trino documentation](#).

## Supported Storage Systems

For more information about Kudu, refer to the [Trino documentation](#).

## Column Type Mapping

Kudu Type	Trino Type	Doris Type	Comment
boolean	boolean	boolean	
int8	tinyint	tinyint	
int16	smallint	smallint	
int32	integer	int	
int64	bigint	bigint	
float	real	float	
double	double	double	
decimal(P, S)	decimal(P, S)	decimal(P, S)	

Kudu Type	Trino Type	Doris Type	Comment
binary	varbinary	string	Requires using HEX(col) in queries to return results displayed the same as in Trino.
string	varchar	string	
date	date	date	
unixtime_micros	timestamp(3) )	datetime(3)	
other		UNSUPPORTED	

## Examples

```
CREATE CATALOG kudu_catalog PROPERTIES (
 'type' = 'trino-connector',
 'trino.connector.name' = 'kudu',
 'trino.kudu.client.master-addresses' = 'ip1:port1,ip2:port2,ip3,port3',
 'trino.kudu.authentication.type' = 'NONE'
);
```

## Query Operations

After configuring the Catalog, you can query the table data in the Catalog using the following methods:

```
-- 1. switch to catalog, use database and query
SWITCH kudu_ctl;
USE kudu_db;
SELECT * FROM kudu_tbl LIMIT 10;

-- 2. use kudu database directly
USE kudu_ctl.kudu_db;
SELECT * FROM kudu_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM kudu_ctl.kudu_db.kudu_tbl LIMIT 10;
```

# Elasticsearch Catalog

Elasticsearch Catalog not only supports automatic mapping of ES metadata, but also combines Doris's distributed query planning capabilities with ES (Elasticsearch)'s full-text search capabilities to provide a more comprehensive OLAP analysis solution:

1. Multi-index distributed Join queries in ES.
2. Joint queries between tables in Doris and ES, with more complex full-text search filtering.

## Prerequisites

Supports Elasticsearch 5.x and above.

## Connecting to Elasticsearch

```
CREATE CATALOG es_catalog PROPERTIES (
 'type' = 'es',
 'hosts' = 'http://127.0.0.1:9200'
 {ElasticsearchProperties}
);
```

- {ElasticsearchProperties}

Parameter	Required	Default	Description
hosts	Yes		ES address, can be one or multiple, or ES load balancer address
user	No	Empty	ES username
password	No	Empty	Password for the corresponding user
doc_value_scan	No	true	Whether to enable getting query field values through ES/Lucene columnar storage
keyword_sniff	No	true	Whether to detect text fields for string tokenization types in ES and query through keyword. Setting to false will match based on tokenized content
nodes_discovery	No	true	Whether to enable ES node discovery, default is true. Set to false in network isolated environments to connect only to specified nodes
ssl	No	false	Whether ES enables https access mode, currently implemented in fe/be as trust all
mapping_es_id	No	false	Whether to map the _id field in ES index
like_push_down	No	true	Whether to convert like to wildcard and push down to ES, will increase ES CPU consumption
include_hidden_index	No	false	Whether to include hidden indexes, default is false

Notes:

1. Authentication currently only supports HTTP Basic authentication, and you need to ensure that the user has access to paths like `/_cluster/state/`, `_nodes/http` and Index read permissions; username and password are not required when cluster security authentication is not enabled.
2. In 5.x and 6.x versions, the first type is taken by default for multiple types in one Index.

## Hierarchy Mapping

Since Elasticsearch doesn't have the concept of Database, after connecting to ES, a unique Database will be automatically generated: `default_db`.

After switching to ES Catalog using the SWITCH command, it will automatically switch to `default_db`, no need to execute `USE default_db` command.

## Column Type Mapping

ES Type	Doris Type	Comment
null	null	
boolean	boolean	
byte	tinyint	
short	smallint	
integer	int	
long	bigint	
unsigned_long	largeint	
float	float	
half_float	float	
double	double	
scaled_float	double	
date	date	Only supports default/yyyy-MM-dd HH:mm:ss/yyyy-MM-dd/epoch_millis formats
keyword	string	
text	string	
ip	string	
constant_keyword	string	
wildcard	string	
nested	json	
object	json	
flattened	json	Supported since version 3.1.4, 4.0.3

ES Type	Doris Type	Comment
other	UNSUPPORTED	

## Array Types

Elasticsearch doesn't have an explicit array type, but its fields can contain [0 or more values](#).

To indicate that a field is an array type, you can add a specific `doris` structure annotation in the `_meta` section of the index mapping.

For Elasticsearch 6.x and earlier versions, please refer to [\\_meta](#).

For example, suppose there's an index `doc` containing the following data structure:

```
{
 "array_int_field": [1, 2, 3, 4],
 "array_string_field": ["doris", "is", "the", "best"],
 "id_field": "id-xxx-xxx",
 "timestamp_field": "2022-11-12T12:08:56Z",
 "array_object_field": [
 {
 "name": "xxx",
 "age": 18
 }
]
}
```

The array fields of this structure can be defined by adding field property definitions to the `_meta.doris` property of the target index mapping using the following commands.

```
ES 7.x and above
curl -X PUT "localhost:9200/doc/_mapping?pretty" -H 'Content-Type:application/json' -d '
{
 "_meta": {
 "doris":{
 "array_fields":[
 "array_int_field",
 "array_string_field",
 "array_object_field"
]
 }
 }
}'

ES 6.x and before
curl -X PUT "localhost:9200/doc/_mapping/_doc?pretty" -H 'Content-Type: application/json' -d '
{
 "_meta": {
 "doris":{
 "array_fields":[
 "array_int_field",
 "array_string_field",
 "array_object_field"
]
 }
 }
}'
```

```
}
}
```

array\_fields: Used to indicate fields that are array types.

## flattened Type

For flattened type, when the enable\_docvalue\_scan property is false, the JSON data format read out is flattened. If the enable\_docvalue\_scan property is true, then the original JSON format is read out. Example as follows:

Index definition:

```
"mappings": {
 "properties": {
 "column1": {
 "type": "keyword"
 },
 "extra": {
 "type": "flattened"
 }
 }
}
```

Data:

```
{
 "column1": 1,
 "extra": {
 "subcol1": "abc",
 "sub_array": [
 {"k1": "element1"},
 {"k2": "element2"},
 {"k3": "element3"}
]
 }
}
```

- When enable\_docvalue\_scan property is false

The query result for extra column is:

```
{
 "subcol1": "abc",
 "sub_array": [
 {"k1": "element1"},
 {"k2": "element2"},
 {"k3": "element3"}
]
}
```

- When enable\_docvalue\_scan property is true

The query result for extra column is:

```
["abc","element1","element2","element3"]
```

## Query Operations

After configuring the Catalog, you can query table data in the Catalog through the following methods:

```
-- 1. switch to catalog, use database and query
SWITCH es_ctl;
SELECT * FROM es_tbl LIMIT 10;

-- 2. use default_db directly
USE es_ctl.default_db;
SELECT * FROM es_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM es_ctl.default_db.es_tbl LIMIT 10;
```

For more advanced query features, please refer to the [Best Practices](#) section.

## Best Practices

### Filter Predicate Pushdown

ES Catalog supports filter predicate pushdown: filter conditions are pushed down to ES, so only data that truly meets the conditions will be returned, which can significantly improve query performance and reduce CPU, Memory, IO usage of Doris and Elasticsearch.

The following operators will be optimized into the corresponding ES Query:

SQL syntax	ES 5.x+ syntax
=	term query
in	terms query
> , < , >= , <=	range query
and	bool.filter
or	bool.should
not	bool.must_not
not in	bool.must_not + terms query
is_not_null	exists query
is_null	bool.must_not + exists query
esquery	ES native json form QueryDSL

### Enable Columnar Scan to Optimize Query Speed (enable\_docvalue\_scan=true)

Set "enable\_docvalue\_scan" = "true"

After enabling, Doris will follow these two principles when getting data from ES:

- **Best Effort:** Automatically detect whether the fields to be read have columnar storage enabled (doc\_value: true). If all fields have columnar storage, Doris will get all field values from columnar storage.
- **Automatic Degradation:** If any field to be retrieved doesn't have columnar storage, all field values will be parsed and retrieved from row storage \_source.

### Advantages:

By default, Doris On ES will get all required columns from row storage, i.e., \_source. \_source storage uses row-based + JSON format, which has inferior batch reading performance compared to columnar storage, especially when only a few columns are needed. In cases where only a few columns are needed, docvalue performance is about ten times better than \_source performance.

### Notes:

1. text type fields don't have columnar storage in ES, so if any field value to be retrieved is of text type, it will automatically degrade to getting from \_source.
2. When the number of fields to retrieve is too many ( $\geq 25$ ), the performance of getting field values from docvalue will be basically the same as getting field values from \_source.
3. keyword type fields may appear empty due to the [ignore\\_above](#) parameter limitation for long text fields that exceed this limit. In this case, you need to disable enable\_docvalue\_scan and get results from \_source.

### Detect Keyword Type Fields

Set "enable\_keyword\_sniff" = "true"

In ES, you can import data directly without establishing an index. In this case, ES will automatically create a new index. For string type fields, ES will create fields that have both text type and keyword type, which is ES's multi fields feature, with mapping as follows:

```
"k4": {
 "type": "text",
 "fields": {
 "keyword": {
 "type": "keyword",
 "ignore_above": 256
 }
 }
}
```

When filtering on k4, such as =, Doris On ES will convert the query to ES's TermQuery.

SQL filter condition:

```
k4 = "Doris On ES"
```

Converted to ES query DSL:

```
"term" : {
 "k4": "Doris On ES"
}
```

Because k4's first field type is text, during data import it will be tokenized according to k4's configured tokenizer (if not set, it's the standard tokenizer) to get three Terms: doris, on, es, as analyzed by ES analyze API:

```
POST /_analyze
{
 "analyzer": "standard",
 "text": "Doris On ES"
}
```

The tokenization result is:

```
{
 "tokens": [
 {
 "token": "doris",
 "start_offset": 0,
 "end_offset": 5,
 "type": "<ALPHANUM>",
 "position": 0
 },
 {
 "token": "on",
 "start_offset": 6,
 "end_offset": 8,
 "type": "<ALPHANUM>",
 "position": 1
 },
 {
 "token": "es",
 "start_offset": 9,
 "end_offset": 11,
 "type": "<ALPHANUM>",
 "position": 2
 }
]
}
```

The query uses:

```
"term" : {
 "k4": "Doris On ES"
}
```

The term Doris On ES cannot match any term in the dictionary and won't return any results. Enabling `enable_keyword_sniff: true` will automatically convert `k4 = "Doris On ES"` to `k4.keyword = "Doris On ES"` to completely match SQL semantics. The converted ES query DSL is:

```
"term" : {
 "k4.keyword": "Doris On ES"
}
```

```
}
```

k4.keyword type is keyword, and data is written to ES as a complete term, so it can match.

### Enable Node Auto Discovery (nodes\_discovery=true)

Set "nodes\_discovery" = "true"

When configured as true, Doris will find all available related data nodes (allocated shards above) from ES. If ES data node addresses are not accessible by Doris BE, set to false. ES cluster is deployed in an intranet isolated from the public Internet, and users access through proxy.

### Whether ES Cluster Enables HTTPS Access Mode

Set "ssl" = "true"

Currently FE/BE implementation is trust all, this is a temporary solution, real user configured certificates will be used later.

### Extended esquery() Function

Use esquery(field, QueryDSL) function to push down some queries that cannot be expressed in SQL, such as match\_phrase, geoshape, etc., to ES for filtering. The first column name parameter of esquery is used to associate index, and the second parameter is the JSON representation of ES's basic Query DSL, enclosed in curly braces {}. The JSON root key must have one and only one, such as match\_phrase, geo\_shape, bool, etc.

match\_phrase query:

```
select * from es_table where esquery(k4, '{
 "match_phrase": {
 "k4": "doris on es"
 }
}');
```

geo related queries:

```
select * from es_table where esquery(k4, '{
 "geo_shape": {
 "location": {
 "shape": {
 "type": "envelope",
 "coordinates": [
 [
 13,
 53
],
 [
 14,
 52
]
]
 }
 },
 "relation": "within"
 }
}');
```

```

 }
 }
}');

```

bool query:

```

select * from es_table where esquery(k4, ' {
 "bool": {
 "must": [
 {
 "terms": {
 "k1": [
 11,
 12
]
 }
 },
 {
 "terms": {
 "k2": [
 100
]
 }
 }
]
 }
}');

```

## Time Type Field Usage Recommendations

Only applicable to ES external tables. In ES Catalog, date types are automatically mapped to Date or Datetime.

In ES, time type fields are very flexible to use, but in ES external tables, if time type fields are not properly configured, filter conditions cannot be pushed down.

When creating an index, set time type format for maximum format compatibility:

```

"dt": {
 "type": "date",
 "format": "yyyy-MM-dd HH:mm:ss||yyyy-MM-dd||epoch_millis"
}

```

When establishing this field in Doris, it's recommended to set it as date or datetime, or it can be set as varchar type. Using the following SQL statements can directly push filter conditions down to ES:

```

select * from doe where k2 > '2020-06-21';

select * from doe where k2 < '2020-06-21 12:00:00';

select * from doe where k2 < 1593497011;

select * from doe where k2 < now();

select * from doe where k2 < date_format(now(), '%Y-%m-%d');

```

**Note:**

- If you don't set format for time type fields in ES, the default time type field format is:

```
strict_date_optional_time||epoch_millis
```

- If date fields imported to ES are timestamps, they need to be converted to ms. ES processes timestamps internally in ms, otherwise ES external tables will have display errors.

## Getting ES Metadata Field ID

When importing documents without specifying `_id`, ES will assign a globally unique `_id` (primary key) to each document. Users can also specify a `_id` with special business meaning when importing.

If you need to get this field value in ES external tables, you can add a `_id` field of `varchar` type when creating the table:

```
CREATE EXTERNAL TABLE `doe` (
 `_id` varchar COMMENT "",
 `city` varchar COMMENT ""
) ENGINE=ELASTICSEARCH
PROPERTIES (
 "hosts" = "http://127.0.0.1:8200",
 "user" = "root",
 "password" = "root",
 "index" = "doe"
}
```

If you need to get this field value in ES Catalog, please set `"mapping_es_id" = "true"`.

### Note:

1. Filter conditions for `_id` field only support `=` and `in`.
2. `_id` field must be of `varchar` type.

## Getting Globally Ordered Query Results

In scenarios like relevance ranking and priority display of important content, it's very useful for ES query results to be sorted by score. Doris queries ES to fully utilize the advantages of MPP architecture by pulling data according to the shard distribution of ES indexes. To get globally ordered sorting results, ES needs to be queried from a single point. This can be controlled by the session variable `enable_es_parallel_scroll` (default is `true`). When `enable_es_parallel_scroll=false` is set, Doris will send `scroll` queries without `shard_preference` and sort information to the ES cluster, thus getting globally ordered results. Note: Use with caution when the query result set is large.

## Modifying scroll Request batch Size

The default batch size for `scroll` requests is 4064. It can be modified through the session variable `batch_size`.

## Frequently Asked Questions

### 1. Does it support ES clusters with X-Pack authentication?

Supports all ES clusters using HTTP Basic authentication.

### 2. Some queries are much slower than requesting ES directly

Yes, such as `_count` related queries, etc. ES will directly read metadata related to the number of documents that meet the conditions internally, without filtering actual data.

### 3. Can aggregation operations be pushed down?

Currently Doris On ES doesn't support pushing down aggregation operations like sum, avg, min/max, etc. The calculation method is to batch stream all documents meeting the conditions from ES, then calculate in Doris.

## Appendix

### Principle of Doris Querying ES

1. FE will request the hosts specified when creating the table to get HTTP port information of all nodes and shard distribution information of indexes, etc. If the request fails, it will traverse the host list sequentially until success or complete failure.
2. When querying, a query plan will be generated and sent to corresponding BE nodes based on some node information and index metadata information obtained by FE.
3. BE nodes will request ES nodes deployed locally first according to the proximity principle. BE gets data concurrently from each shard of ES index through HTTP Scroll method streaming from `_source` or `docvalue`.
4. After Doris completes the calculation, it returns the results to the user.

# LakeSoul Catalog

**Note!**

This feature is deprecated since 3.1.0. For usage inquiries, please contact the developers.

Doris supports accessing and reading LakeSoul table data using metadata stored in PostgreSQL.

[Quickly Experience Apache Doris & LakeSoul with Docker](#)

## Applicable Scenarios

Scenario	Description
Data Integration	Read LakeSoul data and write it to Doris internal tables, or perform ZeroETL operations using the Doris computing engine.
Data Write-back	Not supported.

## Configuring Catalog

### Syntax

```
CREATE CATALOG lakesoul_catalog PROPERTIES (
 'type' = 'lakesoul',
 {LakeSoulProperties},
 {CommonProperties}
);
```

- {LakeSoulProperties}

Property	Description	Example
lakesoul.pg.username	Username for the PG source database	
lakesoul.pg.password	Password for the PG source database	
lakesoul.pg.url	JDBC URL for the PG metadata database	jdbc:postgresql://127.0.0.1:5432/lakesoul_test?stringtype=unspecified

- [CommonProperties]

The CommonProperties section is for filling in general properties. Please refer to the [Data Catalog Overview](#) under the “Common Properties” section.

If LakeSoul data is stored on HDFS, place `core-site.xml`, `hdfs-site.xml`, and `hive-site.xml` in the `conf/` directory of both FE and BE. The Hadoop configuration files in the `conf/` directory are read first, followed by the configuration files specified by the `HADOOP_CONF_DIR` environment variable.

## Supported LakeSoul Versions

The currently supported LakeSoul version is 2.6.2.

## Supported LakeSoul Formats

- Supports LakeSoul primary key and non-primary key tables.
- Supports reading LakeSoul MOR (Merge-On-Read) tables.

## Column Type Mapping

LakeSoul Type	Doris Type	Comment
boolean	boolean	
int8	tinyint	
int16	smallint	
int32	int	
int64	bigint	
float	float	
double	double	
decimal(P, S)	decimal(P, S)	
string	string	
date	date	
timestamp(S)	datetime(S)	
list	array	
map	map	
row	struct	
other	UNSUPPORTED	

## Examples

```
CREATE CATALOG lakesoul PROPERTIES (
 'type' = 'lakesoul',
 'lakesoul.pg.username' = 'lakesoul_test',
 'lakesoul.pg.password' = 'lakesoul_test',
```

```
'lakesoul.pg.url' = 'jdbc:postgresql://127.0.0.1:5432/lakesoul_test?stringtype=unspecified'
);
```

## Query Operations

### Basic Query

Once the Catalog is configured, you can query the table data in the Catalog as follows:

```
-- 1. switch to catalog, use database and query
SWITCH ls_ctl;
USE ls_db;
SELECT * FROM ls_tbl LIMIT 10;

-- 2. use lakesoul database directly
USE ls_ctl.ls_db;
SELECT * FROM ls_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM ls_ctl.ls_db.ls_tbl LIMIT 10;
```

# JDBC Catalog

JDBC Catalog supports connecting to databases that are compatible with the JDBC protocol through a standard JDBC interface.

This document introduces the general configuration and usage of the JDBC Catalog. For different JDBC sources, please refer to the respective documentation.

### Note

The JDBC Catalog feature in Doris relies on the Java layer to read and process data, and its overall performance can be affected by the JDK version. Some internal libraries in older versions of the JDK (such as JDK 8) are less efficient and may lead to higher resource consumption. If higher performance is required, it is recommended to use Doris 3.0, which is compiled with JDK 17 by default and offers better overall performance.

## Applicable Scenarios

The JDBC Catalog is only suitable for data integration, such as importing small amounts of data from a data source into Doris or performing join queries on small tables in a JDBC data source. The JDBC Catalog cannot accelerate queries on the data source or access large amounts of data at once.

## Supported Databases

Doris JDBC Catalog supports connections to the following databases:

Supported Data Sources
<a href="#">MySQL</a>
<a href="#">PostgreSQL</a>
<a href="#">Oracle</a>
<a href="#">SQL Server</a>
<a href="#">IBM DB2</a>
<a href="#">ClickHouse</a>
<a href="#">SAP HANA</a>
<a href="#">Oceanbase</a>

You can refer to the [Developer Guide](#) to develop support for new, unsupported JDBC data sources.

# Configuring Catalog

## Syntax

```
CREATE CATALOG [IF NOT EXISTS] catalog_name PROPERTIES (
 'type' = 'jdbc', -- required
 {JdbcProperties},
 {CommonProperties}
);
```

- {JdbcProperties}
  - Required Properties

Parameter Name	Description	Example
user	Data source username	
password	Data source password	
jdbc_url	Data source connection URL	jdbc:mysql://host:3306
driver_url	Path to the JDBC driver file. For driver package security, see the appendix.	Supports three methods, see below.
driver_class	Class name of the JDBC driver	

driver\_url supports the following three specifications:

1. Filename. For example, mysql-connector-j-8.3.0.jar. The Jar file must be pre-placed in the jdbc\_drivers/ directory under the FE and BE deployment directories. The system will automatically search in this directory. The location can also be modified by the jdbc\_drivers\_dir configuration in fe.conf and be.conf.
2. Local absolute path. For example, file:///path/to/mysql-connector-j-8.3.0.jar. The Jar file must be pre-placed in the specified path on all FE/BE nodes.
3. HTTP URL. For example: https://repo1.maven.org/maven2/com/mysql/mysql-connector-j/8.3.0/mysql-connector-j-8.3.0.jar. The system will download the driver file from this HTTP address. Only supports HTTP services without authentication.

- Optional Properties

Parameter Name	Default Value	Description
lower_case_meta_names	false	Whether to synchronize the database, table, and column names from the external data source in lowercase
meta_names_mapping		When the external data source has names that differ only in case, such as MY_TABLE and my_table, Doris will report an error due to ambiguity when querying the Catalog. You need to configure the meta_names_mapping parameter to resolve conflicts.
only_specified_database	false	Whether to synchronize only the database specified in the jdbc_url (this Database maps to the Database level in Doris)

Parameter Name	Default Value	Description
connection_pool_min_size	1	Defines the minimum number of connections in the connection pool, used to initialize the pool and ensure at least this number of active connections when keep-alive is enabled.
connection_pool_max_size	30	Defines the maximum number of connections in the connection pool. Each FE or BE node corresponding to each Catalog can hold up to this number of connections.
connection_pool_max_wait_time	5000	Defines the maximum wait time in milliseconds for a client to wait for a connection if none are available in the pool.
connection_pool_max_lifetime	1800000	Sets the maximum active duration (in milliseconds) for a connection in the pool. Connections exceeding this time will be recycled. Additionally, half of this value is used as the minimum eviction idle time for the pool, making connections reaching this time eligible for eviction.
connection_pool_keep_alive	false	Effective only on BE nodes, it determines whether to keep connections active that have reached the minimum eviction idle time but not the maximum lifetime. Disabled by default to reduce unnecessary resource usage.

- [CommonProperties]

The CommonProperties section is used to configure common properties. Please refer to the [Catalog Overview](#) section on **Common Properties**.

## Query Operations

### Basic Query

```
-- 1. switch to catalog, use database and query
SWITCH mysql_ctl;
USE mysql_db;
SELECT * FROM mysql_tbl LIMIT 10;

-- 2. use mysql database directly
USE mysql_ctl.mysql_db;
SELECT * FROM mysql_tbl LIMIT 10;

-- 3. use full qualified name to query
SELECT * FROM mysql_ctl.mysql_db.mysql_tbl LIMIT 10;
```

### Query Optimization

#### Predicate Pushdown

When the JDBC Catalog accesses a data source, it essentially selects a BE node, uses the JDBC Client to send a generated SQL query to the source, and retrieves the data. Therefore, the performance depends solely on how efficiently the generated SQL executes on the source side. Doris will attempt to push down predicate conditions and incorporate them into the generated SQL. You can use the EXPLAIN SQL statement to view the generated SQL.

```
EXPLAIN SELECT smallint_u, sum(int_u)
FROM all_types WHERE smallint_u > 10 GROUP BY smallint_u;
```

```

...
| 0:VJdbcScanNode(206) |
| TABLE: `doris_test`.`all_types` |
| QUERY: SELECT `smallint_u`, `int_u` FROM `doris_test`.`all_types` WHERE ((`smallint_u` > 10)) |
| PREDICATES: (smallint_u[#1] > 10) |
| final projections: smallint_u[#1], int_u[#3] |
| final project output tuple id: 1 |
...

```

## Function Pushdown

For predicate conditions, the semantics or behavior in Doris and external data sources may be inconsistent. Therefore, Doris restricts and controls predicate pushdown in JDBC external table queries through the following parameter variables:

Note: Currently, Doris only supports predicate pushdown for MySQL, Clickhouse, and Oracle data sources. More data sources will be supported in the future.

- `enable_jdbc_oracle_null_predicate_push_down`

Session variable. The default is `false`. That is, when the predicate condition contains a `NULL` value, the predicate will not be pushed down to the Oracle data source. This is because, before Oracle version 21, Oracle does not support `NULL` as an operator.

This parameter is supported since 2.1.7 and 3.0.3.

- `enable_jdbc_cast_predicate_push_down`

Session variable. The default is `false`. That is, when there is an explicit or implicit `CAST` in the predicate condition, the predicate will not be pushed down to the JDBC data source. Since the behavior of `CAST` is inconsistent across different databases, to ensure correctness, `CAST` is not pushed down by default. However, users can manually verify whether the behavior of `CAST` is consistent. If so, this parameter can be set to `true` to allow more predicates to be pushed down for better performance.

This parameter is supported since 2.1.7 and 3.0.3.

- Function pushdown blacklist and whitelist

Functions with the same signature may have inconsistent semantics in Doris and external data sources. Doris has predefined some blacklists and whitelists for function pushdown:

Data Source	Blacklist	Whitelist	Description
MySQL	- DATE_TRUNC - MONEY_FORMAT - NEGATIVE		MySQL can also set additional blacklist items through the FE configuration item <code>jdbc_mysql_unsupported_pushdown_functions</code> , e.g.: <code>jdbc_mysql_unsupported_pushdown_functions==func1,func2</code>

Data Source	Blacklist	Whitelist	Description
Clickhouse		- FROM_UNIX TIME - UNIX_TIME STAMP	
Oracle		- NVL - IFNULL	

- Function rewrite rules

There are some functions in Doris and external data sources that have consistent behavior but different names. Doris supports rewriting these functions during function pushdown. The following rewrite rules are currently built-in:

Data Source	Doris Function	Target Function
MySQL	nvl	ifnull
MySQL	to_date	date
Clickhouse	from_unixtime	FROM_UNIXTIME
Clickhouse	unix_timestamp	toUnixTimestamp
Oracle	ifnull	nvl

- Custom function pushdown and rewrite rules

In subsequent versions after 3.0.7, Doris supports more flexible function pushdown and rewrite rules. Users can set function pushdown and rewrite rules for a specific Catalog in the Catalog properties:

```
create catalog jdbc properties (
...
'function_rules' = '{"pushdown" : {"supported": ["to_date"], "unsupported" : ["abs"]}, "rewrite" : {"to_date" : "date2"}}'
)
```

Through `function_rules`, the following rules can be specified:

- pushdown

Specifies function pushdown rules. The supported and unsupported arrays specify the function names that can and cannot be pushed down, respectively. If a function exists in both arrays, supported takes precedence.

Doris will first apply the system's predefined blacklists and whitelists, and then apply the user-specified blacklists and whitelists.

- rewrite

Defines function rewrite rules. As in the example above, the function name `to_date` will be rewritten as `date2` and pushed down.

Note: Only functions that are allowed to be pushed down will be rewritten.

## Row Count Limitation

If a query includes the LIMIT keyword, Doris will push the LIMIT clause down to the data source to reduce data transfer volume. You can use the EXPLAIN statement to confirm whether the generated SQL includes the LIMIT clause.

## Write Operations

Doris supports writing data back to the corresponding data source via the JDBC protocol.

```
INSERT INTO mysql_table SELECT * FROM internal.doris_db.doris_tbl;
```

## Statement Passthrough

### Applicable Scenarios

Doris supports directly executing corresponding DDL, DML, and query statements in the JDBC data source through statement passthrough. This feature is applicable in the following scenarios:

- Improving Complex Query Performance

By default, the Doris query optimizer parses the original SQL and generates the SQL to be sent to the data source based on certain rules. This generated SQL is typically a simple single-table query and cannot include operators like aggregation or join queries. For example, consider the following query:

```
SELECT smallint_u, sum(int_u)
FROM all_types WHERE smallint_u > 10 GROUP BY smallint_u;
```

The final generated SQL would be:

```
SELECT smallint_u, int_u
FROM all_types
WHERE smallint_u > 10;
```

In this case, the aggregation operation is performed within Doris. Therefore, in some scenarios, a large amount of data may need to be read from the source over the network, resulting in low query efficiency. With statement passthrough, the original SQL can be directly passed to the data source, leveraging the data source's own computation capabilities to execute the SQL, thereby improving query performance.

- Unified Management

In addition to query SQL, the statement passthrough feature can also pass DDL and DML statements. This allows users to perform database and table operations on the source data directly through Doris, such as creating, deleting tables, or modifying table structures.

## Passthrough SQL

```
SELECT * FROM
QUERY(
 'catalog' = 'mysql_catalog',
 'query' = 'SELECT smallint_u, sum(int_u) FROM db.all_types WHERE smallint_u > 10 GROUP BY smallint_u;'
);
```

The QUERY table function takes two parameters:

- catalog: The name of the catalog, which should match the name of the catalog.
- query: The query statement to execute, written directly using the syntax of the corresponding data source.

## Passthrough DDL and DML

```
CALL EXECUTE_STMT("jdbc_catalog", "insert into db1.tbl1 values(1,2), (3, 4)");

CALL EXECUTE_STMT("jdbc_catalog", "delete from db1.tbl1 where k1 = 2");

CALL EXECUTE_STMT("jdbc_catalog", "create table db1.tbl2 (k1 int)");
```

The EXECUTE\_STMT() function takes two parameters:

- First parameter: The name of the catalog. Currently, only JDBC-type catalogs are supported.
- Second parameter: The SQL statement to execute. Currently, only DDL and DML statements are supported, and they must be written using the syntax of the corresponding data source.

## Usage Restrictions

When using the CALL EXECUTE\_STMT() command, Doris directly sends the user-written SQL statement to the JDBC data source associated with the catalog for execution. As a result, this operation has the following restrictions:

- The SQL statement must follow the syntax of the corresponding data source. Doris does not perform syntax or semantic checks.
- Table names referenced in the SQL statement should preferably use fully qualified names, such as db.tbl. If the database is not specified, the database name in the JDBC URL of the JDBC catalog will be used.
- The SQL statement cannot reference databases or tables outside the JDBC data source, nor can it reference Doris's databases or tables. However, it can reference tables within the JDBC data source that are not synchronized with the Doris JDBC catalog.
- When executing DML statements, the number of rows inserted, updated, or deleted cannot be retrieved; only the success or failure of the command can be determined.
- Only users with LOAD permission on the catalog can execute the CALL EXECUTE\_STMT() command.
- Only users with SELECT permission on the catalog can execute the query() table function.

- The JDBC user specified when creating the catalog must have the necessary permissions on the source to execute the corresponding statements.
- The data types of the results read by the query ( ) table function are consistent with the data types supported by the queried catalog type.

## Appendix

### Case Sensitivity Settings

By default, database and table names in Doris are case-sensitive, while column names are case-insensitive. This behavior can be modified through configuration parameters. Additionally, the case sensitivity rules for database, table, and column names in some JDBC data sources may differ from those in Doris. This discrepancy can cause naming conflicts during name mapping via the JDBC Catalog. The following section explains how to resolve such issues.

### Display Name and Query Name

In Doris, an object name (here we use table names as an example) can be divided into a **Display Name** and a **Query Name**. For instance, for a table name, the **Display Name** refers to the name shown in the result of SHOW TABLES, while the **Query Name** refers to the name that can be used in a SELECT statement.

For example, if the actual name of a table is MyTable, the **Display Name** and **Query Name** of this table may differ depending on the configuration of the Frontend (FE) parameter lower\_case\_table\_names:

Configuration	Description	Actual Name	Display Name	Query Name
lower_case_table_names=0	Default configuration. The original name is stored and displayed, and queries are case-sensitive.	MyTable	MyTable	Case-sensitive in queries, must use: MyTable
lower_case_table_names=1	The name is stored and displayed in lowercase, and queries are case-insensitive.	MyTable	mytable	Case-insensitive in queries, e.g., you can use MyTable or mytable.
lower_case_table_names=2	The original name is stored and displayed, but queries are case-insensitive.	MyTable	MyTable	Case-insensitive in queries, e.g., you can use MyTable or mytable.

### JDBC Catalog Name Case Sensitivity Rules

Doris itself only allows configuration of the case sensitivity rules for **table names**. However, JDBC Catalog requires additional handling for **database names** and **column names**. Therefore, we use an additional Catalog property, lower\_case\_meta\_names, to work in conjunction with lower\_case\_table\_names.

Configuration	Description
lower_case_meta_names	Specified via properties when creating a Catalog, and it applies only to that Catalog. The default value is false. When set to true, Doris converts all database, table, and column names to lowercase for storage and display. Queries must use the lowercase names in Doris.
lower_case_table_names	A Frontend (FE) configuration item, configured in fe.conf, and it applies to the entire cluster. The default value is 0.

Note: If lower\_case\_meta\_names = true, the lower\_case\_table\_names configuration will be ignored, and all database, table, and column names will be converted to lowercase.

Based on the combinations of lower\_case\_meta\_names (true/false) and lower\_case\_table\_names (0/1/2), the behavior of database, table, and column names during **storage** and **queries** is shown in the following table (“Original” means retaining the case from the external data source, “Lowercase” means automatically converting to lowercase, and “Any Case” means queries can use any case):

lower_case_table_names & lower_case_meta_names	Database Display Name	Table Display Name	Column Display Name	Database Query Name	Table Query Name	Column Query Name
0 & false	Original	Original	Original	Original	Original	Any Case
0 & true	Lowercase	Lowercase	Lowercase	Lowercase	Lowercase	Any Case
1 & false	Original	Lowercase	Original	Original	Any Case	Any Case
1 & true	Lowercase	Lowercase	Lowercase	Lowercase	Any Case	Any Case
2 & false	Original	Original	Original	Original	Any Case	Any Case
2 & true	Lowercase	Lowercase	Lowercase	Lowercase	Any Case	Any Case

## Case Conflict Check

When performing name mapping through a JDBC Catalog, naming conflicts may occur. For example, if the source column names are case-sensitive and there are two columns, ID and id. If lower\_case\_meta\_names = true is set, these two columns will conflict after being converted to lowercase. Doris performs conflict checks according to the following rules:

- In any scenario, Doris will check for **column name** case conflicts (e.g., whether id and ID exist simultaneously).
- When lower\_case\_meta\_names = true, Doris will check for case conflicts in database names, table names, and column names (e.g., whether DORIS and doris exist simultaneously).
- When lower\_case\_meta\_names = false and lower\_case\_table\_names is set to 1 or 2, Doris will check for **table name** conflicts (e.g., whether orders and ORDERS exist simultaneously).
- When lower\_case\_table\_names = 0, database and table names are case-sensitive, and no additional conversion is required.

## Solutions to Case Conflicts

When conflicts occur, Doris will throw an error, and the conflicts must be resolved using the following approach.

For cases where databases, tables, or columns with only case differences (e.g., DORIS and doris) cause Doris to be unable to distinguish them properly, you can resolve the conflict by setting `meta_names_mapping` for the Catalog to specify manual mappings.

### Examples

```
{
 "databases": [
 {
 "remoteDatabase": "DORIS",
 "mapping": "doris_1"
 },
 {
 "remoteDatabase": "doris",
 "mapping": "doris_2"
 }
],
 "tables": [
 {
 "remoteDatabase": "DORIS",
 "remoteTable": "DORIS",
 "mapping": "doris_1"
 },
 {
 "remoteDatabase": "DORIS",
 "remoteTable": "doris",
 "mapping": "doris_2"
 }
],
 "columns": [
 {
 "remoteDatabase": "DORIS",
 "remoteTable": "DORIS",
 "remoteColumn": "DORIS",
 "mapping": "doris_1"
 },
 {
 "remoteDatabase": "DORIS",
 "remoteTable": "DORIS",
 "remoteColumn": "doris",
 "mapping": "doris_2"
 }
]
}
```

## Driver Package Security

Driver packages are uploaded by users to the Doris cluster, which poses certain security risks. Users can enhance security through the following measures:

1. Doris considers all driver packages in the `jdbc_drivers_dir` directory to be secure and does not perform path checks on them. Administrators must manage the files in this directory themselves to ensure their security.

2. If a driver package is specified using a local path or an HTTP path, Doris performs the following checks:

- The allowed driver package paths are controlled via the FE configuration item `jdbc_driver_secure_path`. This configuration can include multiple paths, separated by semicolons. When this configuration is set, Doris checks whether the `driver_url` path prefix is included in `jdbc_driver_secure_path`. If it is not included, the creation will be denied.

Example:

If `jdbc_driver_secure_path = "file:///path/to/jdbc_drivers;http:///path/to/jdbc_drivers"` is configured, only driver package paths starting with `file:///path/to/jdbc_drivers` or `http:///path/to/jdbc_drivers` are allowed.

- This parameter defaults to `*`. If it is empty or set to `*`, all Jar package paths are allowed.

3. When creating a data directory, you can specify the checksum of the driver package using the `checksum` parameter. After loading the driver package, Doris will validate the checksum, and if the validation fails, the creation will be denied.

## Connection Pool Cleanup

In Doris, each FE and BE node maintains a connection pool to avoid the frequent opening and closing of individual data source connections. Each connection in the pool can be used to establish a connection with the data source and execute queries. After the task is completed, these connections are returned to the pool for reuse, which not only improves performance but also reduces the system overhead of establishing connections and helps prevent reaching the connection limit of the data source.

The size of the connection pool can be adjusted according to actual needs to better accommodate different workloads. Typically, the minimum number of connections in the pool should be set to 1 to ensure that at least one connection remains active when the keep-alive mechanism is enabled. The maximum number of connections should be set to a reasonable value to avoid excessive resource consumption.

To prevent the accumulation of unused connection pool caches on the BE, you can set the `jdbc_connection_pool_cache_clear_time_sec` parameter on the BE to specify the cache cleanup interval. The default value is 28,800 seconds (8 hours), after which the BE will forcibly clear all connection pool caches that have not been used within this time.

## Credential Update

When using the JDBC Catalog to connect to external data sources, it is important to carefully update database credentials.

Doris maintains active connections through the connection pool to respond quickly to queries. However, after changing credentials, the connection pool might continue using the old credentials to attempt new connections and fail. Since the system tries to maintain a certain number of active connections, these erroneous attempts will be repeated, and in some database systems, frequent failures might lead to account lockout.

It is recommended to update the Doris JDBC Catalog configuration in sync when credentials must be changed and restart the Doris cluster to ensure all nodes use the latest credentials, preventing connection failures and

potential account lockouts.

Possible account lockouts include:

MySQL: account is locked

Oracle: ORA-28000: the account is locked

SQL Server: Login is locked out

## Connection Pool Troubleshooting

### 1. HikariPool Connection Timeout Error: Connection is not available, request timed out after 5000ms

#### ◦ Possible Causes

- Cause 1: Network issues (e.g., server unreachable)
- Cause 2: Authentication issues, such as invalid username or password
- Cause 3: High network latency causing connection creation to exceed the 5-second timeout
- Cause 4: Too many concurrent queries exceeding the maximum connections configured in the pool

#### ◦ Solutions

- If you only encounter the error Connection is not available, request timed out after 5000ms, check Causes 3 and 4:

- Check for high network latency or resource exhaustion.
- Increase the maximum number of connections in the pool:

```
ALTER CATALOG catalog_name SET PROPERTIES ('connection_pool_max_size' = '100');
```

- Increase the connection timeout:

```
ALTER CATALOG catalog_name SET PROPERTIES ('connection_pool_max_wait_time' = '10000');
```

- If there are additional error messages besides Connection is not available, request timed out after 5000ms, check these additional errors:
  - Network issues (e.g., server unreachable) may cause connection failures. Ensure the network connection is stable.
  - Authentication issues (e.g., invalid username or password) may also cause connection failures. Verify the database credentials in the configuration to ensure the username and password are correct.

- Investigate issues related to network, database, or authentication based on the specific error messages to identify the root cause.

# MySQL JDBC Catalog

---

Doris JDBC Catalog supports connecting to MySQL databases via the standard JDBC interface. This document describes how to configure MySQL database connections.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

## Usage Notes

To connect to a MySQL database, you need:

- MySQL 5.7, 8.0, or higher.
- The JDBC driver for MySQL, which you can download from the [Maven Repository](#). It is recommended to use MySQL Connector/J version 8.0.31 or above.
- Network connection between each Doris FE and BE node and the MySQL server, with the default port being 3306.

## Connecting to MySQL

```
CREATE CATALOG mysql_catalog PROPERTIES (
 'type' = 'jdbc',
 'user' = 'username',
 'password' = 'pwd',
 'jdbc_url' = 'jdbc:mysql://host:3306',
 'driver_url' = 'mysql-connector-j-8.3.0.jar',
 'driver_class' = 'com.mysql.cj.jdbc.Driver'
);
```

The `jdbc_url` defines the connection information and parameters to be passed to the MySQL JDBC driver. Supported URL parameters can be found in the [MySQL Developer Guide](#).

## Connection Security

If the user has configured TLS with a globally trusted certificate installed on the data source, TLS can be enabled between the cluster and the data source by appending parameters to the JDBC connection string set in the `jdbc_url` property.

For example, for MySQL Connector/J 8.0, use the `sslMode` parameter to secure the connection via TLS. By default, this parameter is set to `PREFERRED`, which can secure the connection if the server is enabled. This parameter can also be set to `REQUIRED`, which will cause the connection to fail if TLS is not established.

It can be configured by adding the `sslMode` parameter in the `jdbc_url`:

```
'jdbc_url' = 'jdbc:mysql://host:3306/?sslMode=REQUIRED'
```

For more information on TLS configuration options, please refer to the [MySQL JDBC Security Documentation](#).

## Hierarchical Mapping

When mapping MySQL, a Database in Doris corresponds to a Database in MySQL. A Table under a Database in Doris corresponds to Tables under that Database in MySQL. The mapping relationship is as follows:

Doris	MySQL
Catalog	MySQL Server
Database	Database
Table	Table

## Column Type Mapping

MySQL Type	Doris Type	Comment
boolean	tinyint	
tinyint	tinyint	
smallint	smallint	
mediumint	int	
int	int	
bigint	bigint	
unsigned tinyint	smallint	Doris does not support unsigned data types, so unsigned data types are mapped to the corresponding larger data type in Doris.
unsigned mediumint	int	Same as above.
unsigned int	bigint	Same as above.
unsigned bigint	largeint	Same as above.
float	float	
double	double	
decimal(P, S)	decimal(P, S)	
unsigned decimal(P, S)	decimal(P + 1, S) / string	If it exceeds the maximum precision supported by Doris, it will be handled by String. Note that when this type is mapped to String, it only supports queries and cannot write to MySQL.
date	date	
timestamp(S)	datetime(S)	
datetime(S)	datetime(S)	
year	smallint	Doris does not support the year type, so the year type is mapped to smallint.
time	string	Doris does not support the time type, so the time type is mapped to string.
char	char	
varchar	varchar	

MySQL Type	Doris Type	Comment
json	string	For better balance between reading and computing performance, Doris maps the json type to the string type.
set	string	
enum	string	
bit	boolean / string	Doris does not support the bit type, so the bit type is mapped to boolean when bit(1), and to string in other cases.
tinytext, text, mediumtext, longtext	string	
blob, mediumblob, longblob, tinyblob, binary, varbinary	string/varbinary	Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is <code>false</code> , which maps to <code>string</code> ; when <code>true</code> , it maps to <code>varbinary</code> type.
other	UNSUPPORTED	

## Appendix

### Time Zone Issues

When accessing data through JDBC Catalog, the JNI part of BE uses the JVM time zone. The JVM time zone defaults to the time zone of the BE deployment machine, which affects time zone conversion when JDBC reads data. To ensure time zone consistency, it is recommended to set the JVM time zone in `be.conf`'s `JAVA_OPTS` to be consistent with the Doris session variable `time_zone`.

When reading MySQL's timestamp type, add the parameters `connectionTimeZone=LOCAL` and `forceConnectionTimeZoneToSession=true` in the JDBC URL. These parameters are applicable to MySQL Connector/J version 8 and above, ensuring that the read time is the Doris BE JVM time zone, not the MySQL server's time zone.

## Common Issues

### Connection Exception Troubleshooting

- Communications link failure The last packet successfully received from the server was 7 milliseconds ago.
  - Cause:
    - Network issues:
      - Unstable network or connection interruption.
      - High network latency between the client and server.
    - MySQL server settings
      - The MySQL server may have configured connection timeout parameters, such as `wait_timeout` or `interactive_timeout`, causing the connection to be closed due

to timeout.

- Firewall settings
    - Firewall rules may block communication between the client and server.
  - Connection pool settings
    - The configuration `connection_pool_max_life_time` in the connection pool may cause the connection to be closed or recycled, or not kept alive in time.
  - Server resource issues
    - The MySQL server may lack resources to handle new connection requests.
  - Client configuration
    - Incorrect client JDBC driver configuration, such as the `autoReconnect` parameter not set or set improperly.
- Solution
- Check network connection:
    - Ensure stable network connection between the client and server, avoiding high network latency.
  - Check MySQL server configuration:
    - Review and adjust the MySQL server's `wait_timeout` and `interactive_timeout` parameters to ensure they are set reasonably.
  - Check firewall configuration:
    - Ensure firewall rules allow communication between the client and server.
  - Adjust connection pool settings:
    - Review and adjust the connection pool's configuration parameters `connection_pool_max_life_time`, ensuring it is less than MySQL's `wait_timeout` and `interactive_timeout` parameters and greater than the longest execution time of SQL.
  - Monitor server resources:
    - Monitor the MySQL server's resource usage to ensure there are enough resources to handle connection requests.
  - Optimize client configuration:
    - Ensure the JDBC driver's configuration parameters are correct, such as `autoReconnect=true`, to ensure the connection can automatically reconnect after interruption.

- java.io.EOFException MESSAGE: Can not read response from server. Expected to read 819 bytes, read 686 bytes before connection was unexpectedly lost.
  - Cause: Connection was killed by MySQL or MySQL crashed
  - Solution: Check if MySQL has a mechanism to actively kill connections, or if a large query crashed MySQL

## Other Issues

### 1. Garbled characters when reading and writing MySQL emoji

When Doris queries MySQL, the default utf8 encoding in MySQL is utf8mb3, which cannot represent emoji that require 4-byte encoding. Here, you need to change MySQL's encoding to utf8mb4 to support 4-byte encoding.

You can globally modify the configuration item

```
Modify the my.ini file in the mysql directory (for Linux systems, it is the my.cnf file in the etc directory)
[client]
default-character-set=utf8mb4

[mysql]
Set mysql default character set
default-character-set=utf8mb4

[mysqld]
Set mysql character set server
character-set-server=utf8mb4
collation-server=utf8mb4_unicode_ci
init_connect='SET NAMES utf8mb4'

Modify the type of the corresponding table and column
ALTER TABLE table_name MODIFY colum_name VARCHAR(100) CHARACTER SET utf8mb4 COLLATE
utf8mb4_unicode_ci;
ALTER TABLE table_name CHARSET=utf8mb4;
SET NAMES utf8mb4
```

### 2. Exception when reading MySQL DATE/DATETIME type

```
ERROR 1105 (HY000): errCode = 2, detailMessage = (10.16.10.6)[INTERNAL_ERROR]UdfRuntimeException: get
next block failed:
CAUSED BY: SQLException: Zero date value prohibited
CAUSED BY: DataReadException: Zero date value prohibited
```

In JDBC, illegal DATE/DATETIME is handled by default by throwing an exception. The behavior can be controlled by the URL parameter `zeroDateTimeBehavior`. The optional parameters are: `exception`, `convertToNull`, `round`, which are: `exception error`; `convert to NULL value`; `convert to "0001-01-01 00:00:00"`

You need to add `zeroDateTimeBehavior=convertToNull` to the JDBC connection string at the end of the `jdbc_url` when creating the Catalog, such as `"jdbc_url" = "jdbc:mysql://127.0.0.1:3306/test?zeroDateTimeBehavior=convertToNull"`. In this case, JDBC

will convert 0000-00-00 or 0000-00-00 00:00:00 to null, and then Doris will handle all Date/DateTime type columns of the current Catalog as nullable types, so they can be read normally.

3. When reading MySQL Catalog or other JDBC Catalog, class loading failure occurs, such as failed to load driver class `com.mysql.cj.jdbc.driver` in either of hikariconfig class loader

This is because the `driver_class` filled in when creating the Catalog is incorrect and needs to be filled in correctly, such as the example above is a case issue, it should be filled in as `'driver_class' = 'com.mysql.cj.jdbc.Driver'`

4. Communication link exception when reading MySQL

```
ERROR 1105 (HY000): errCode = 2, detailMessage = PoolInitializationException: Failed to initialize pool:
Communications link failure
```

```
The last packet successfully received from the server was 7 milliseconds ago. The last packet sent
successfully to the server was 4 milliseconds ago.
```

```
CAUSED BY: CommunicationsException: Communications link failure
```

```
The last packet successfully received from the server was 7 milliseconds ago. The last packet sent
successfully to the server was 4 milliseconds ago.
```

```
CAUSED BY: SSLHandshakeException
```

You can check the `be.out` log of `be`, if it contains the following information:

```
WARN: Establishing SSL connection without server's identity verification is not recommended.
```

```
According to MySQL 5.5.45+, 5.6.26+ and 5.7.6+ requirements SSL connection must be established by default if
explicit option isn't set.
```

```
For compliance with existing applications not using SSL the verifyServerCertificate property is set to
'false'.
```

```
You need either to explicitly disable SSL by setting useSSL=false, or set useSSL=true and provide truststore
for server certificate verification.
```

You can add `useSSL=false` in the `jdbc_url`, such as `'jdbc_url' = 'jdbc:mysql://127.0.0.1:3306/test?useSSL=false'`.

- When querying large amounts of data from MySQL, if the query occasionally succeeds and occasionally reports the following error, and when this error occurs, all connections to MySQL are disconnected and cannot connect to the MySQL Server, but after a while, MySQL returns to normal, but the previous connections are gone:

```
ERROR 1105 (HY000): errCode = 2, detailMessage = [INTERNAL_ERROR]UdfRuntimeException: JDBC executor
sql has error:
```

```
CAUSED BY: CommunicationsException: Communications link failure
```

```
The last packet successfully received from the server was 4,446 milliseconds ago. The last packet sent
successfully to the server was 4,446 milliseconds ago.
```

When the above phenomenon occurs, it may be that the MySQL Server's own memory or CPU resources are exhausted, causing the MySQL service to be unavailable. You can try to increase the memory or CPU configuration of the MySQL Server.

- During the process of querying MySQL, if you find that the query results are inconsistent with those in the MySQL database

First, check whether there are case-sensitive situations in the query fields. For example, if there are two pieces of data "aaa" and "AAA" in a field c\_1 in the Table, if the MySQL database is not specified to distinguish case when initialized, MySQL does not distinguish case by default, but Doris strictly distinguishes case, so the following situation will occur:

```
MySQL behavior:
select count(c_1) from table where c_1 = "aaa"; Does not distinguish case, so the result is: 2

Doris behavior:
select count(c_1) from table where c_1 = "aaa"; Strictly distinguishes case, so the result is: 1
```

If the above phenomenon occurs, you need to adjust according to the requirements, as follows:

- Add the "BINARY" keyword in MySQL queries to force case sensitivity: `select count(c_1) from table where BINARY c_1 = "aaa";`
- Or specify when creating a table in MySQL: `CREATE TABLE table (c_1 VARCHAR(255) CHARACTER SET binary);`
- Or specify collation rules to distinguish case when initializing the MySQL database:

```
``text
[mysqld]
character-set-server=utf8
collation-server=utf8_bin
[client]
default-character-set=utf8
[mysql]
default-character-set=utf8
````
```

- When querying MySQL, if it gets stuck for a long time without returning results, or gets stuck for a long time and a large number of write lock logs appear in fe.warn.log.

You can try adding `socketTimeout` to the URL, for example: `jdbc:mysql://host:port/database?socketTimeout=30000`, to prevent the JDBC client from waiting indefinitely after being closed by MySQL.

- During the use of MySQL Catalog, if you find that the JVM memory or Threads number of FE continues to grow without decreasing, and may simultaneously report Forward to master connection timed out error

Print the FE thread stack `jstack fe_pid > fe.js`, if a large number of `mysql-cj-abandoned-connection-cleanup` threads appear, it indicates a problem with the MySQL JDBC driver.

Handle it as follows:

- Upgrade the MySQL JDBC driver to version 8.0.31 or above
- Add the parameter `-Dcom.mysql.cj.disableAbandonedConnectionCleanup=true` in the `JAVA_OPTS` of the FE and BE conf files to disable the connection cleanup function of the MySQL JDBC driver, and restart the cluster

Note: If the version of Doris is 2.0.13 or above, or 2.1.5 or above, there is no need to add this parameter, because Doris has already disabled the connection cleanup function of the MySQL JDBC driver by default. Just replace the MySQL JDBC driver version. However, you need to restart the Doris cluster to clean up the previously leaked threads.

PostgreSQL JDBC Catalog

Doris JDBC Catalog supports connecting to PostgreSQL databases via the standard JDBC interface. This document describes how to configure a PostgreSQL database connection.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to a PostgreSQL database, you need

- PostgreSQL 11.x or higher
- JDBC driver for PostgreSQL database, which you can download the latest or specified version from [Maven Repository](#). It is recommended to use PostgreSQL JDBC Driver version 42.5.x or above.
- Network connection between each FE and BE node of Doris and the PostgreSQL server, with the default port being 5432.

Connecting to PostgreSQL

```
CREATE CATALOG postgresql_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password' = 'pwd',  
  'jdbc_url' = 'jdbc:postgresql://host:5432/postgres',  
  'driver_url' = 'postgresql-42.5.6.jar',  
  'driver_class' = 'org.postgresql.Driver'  
);
```

`jdbc_url` defines the connection information and parameters to be passed to the PostgreSQL JDBC driver. Supported URL parameters can be found in the [PostgreSQL JDBC Driver Documentation](#).

Connection Security

If you have configured TLS with a globally trusted certificate installed on the data source, you can enable TLS between the cluster and the data source by appending parameters to the JDBC connection string set in the `jdbc_url` property.

For example, for version 42 of the PostgreSQL JDBC driver, enable TLS by adding the `ssl=true` parameter to the `jdbc_url` configuration property:

```
"jdbc_url"="jdbc:postgresql://example.net:5432/database?ssl=true"
```

For more information on TLS configuration options, please refer to the [PostgreSQL JDBC Driver Documentation](#).

Hierarchical Mapping

When mapping PostgreSQL, a Database in Doris corresponds to a Schema under a specified database in PostgreSQL (as in the example `jdbc_url` parameter under `postgres`). A Table under a Database in Doris corresponds to Tables under that Schema in PostgreSQL. The mapping relationship is as follows:

| Doris | PostgreSQL |
|----------|------------|
| Catalog | Database |
| Database | Schema |
| Table | Table |

Column Type Mapping

| PostgreSQL Type | Doris Type | |
|---|------------------------|---|
| boolean | boolean | |
| smallint/int2 | smallint | |
| integer/int4 | int | |
| bigint/int8 | bigint | |
| decimal/numeric | decimal(P, S) / string | Numeric without precision will be mapped to string type, and needs to be converted to decimal type for numerical calculations, and does not support write-back. |
| real/float4 | float | |
| double | double | |
| smallserial | smallint | |
| serial | int | |
| bigserial | bigint | |
| char(N) | char(N) | |
| varchar/text | string | |
| timestamp(S)/timestampz(S) | datetime(S) | |
| date | date | |
| json/jsonb | string | For better reading and computing performance balance, Doris maps JSON type to STRING type. |
| time | string | Doris does not support time type, time type will be mapped to string. |
| interval | string | |
| point/line/lseg/box/path/polygon/circle | string | |
| cidr/inet/macaddr | string | |
| uuid | string | |
| bit | boolean / string | Doris does not support bit type, bit type will be mapped to boolean when bit(1), otherwise mapped to string. |

| PostgreSQL Type | Doris Type | |
|-----------------|-------------|---|
| bytea | varbinary | Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is <code>false</code> , which maps to <code>string</code> ; when <code>true</code> , it maps to <code>varbinary</code> type. |
| array | array | Please refer to the following explanation regarding the mapping methods for array types. |
| other | UNSUPPORTED | |

- Array Types

In PostgreSQL, array types can be defined as follows:

```
col1 text[]
col2 int4[][]
```

However, the array dimensions cannot be directly obtained from the PostgreSQL metadata. For example, `text []` could be a one-dimensional array or a two-dimensional array. The array dimensions can only be determined after data is written.

Doris requires the array dimensions to be explicitly declared. Therefore, Doris can only map correctly if the corresponding array column in PostgreSQL contains data; otherwise, the array column will be mapped as `UNSUPPORTED`.

Appendix

Time Zone Issues

Since Doris does not support timestamp types with time zones, when reading the `timestampz` type from PostgreSQL, Doris will map it to `DATETIME` type and convert it to local time zone time when reading.

And because when reading data from JDBC type Catalog, the Java part of BE uses the JVM time zone. The JVM time zone defaults to the time zone of the BE deployment machine, which affects the time zone conversion when JDBC reads data.

To ensure time zone consistency, it is recommended to set the JVM time zone in `JAVA_OPTS` of `be.conf` to be consistent with the `time_zone` of Doris session.

Oracle JDBC Catalog

Apache Doris JDBC Catalog supports connecting to Oracle databases via the standard JDBC interface. This document describes how to configure Oracle database connections.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to an Oracle database, you need

- Oracle 19c, 18c, 12c, 11g, or 10g.
- The JDBC driver for Oracle databases, which you can download from the [Maven Repository](#) for Ojdbc8 and above versions of the Oracle JDBC driver.
- Network connection between each FE and BE node of Apache Doris and the Oracle server, with the default port being 1521; if Oracle RAC is ONS-enabled, port 6200 is also required.

Connecting to Oracle

```
CREATE CATALOG oracle_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password'='pwd',  
  'jdbc_url' = 'jdbc:oracle:thin:@example.net:1521:orcl',  
  'driver_url' = 'ojdbc8.jar',  
  'driver_class' = 'oracle.jdbc.driver.OracleDriver'  
)
```

jdbc_url defines the connection information and parameters to be passed to the JDBC driver. When using the Oracle JDBC Thin driver, the syntax of the URL may vary depending on your Oracle configuration. For example, if you are connecting to an Oracle SID or Oracle service name, the connection URL will differ. For more information, please refer to the [Oracle Database JDBC Driver Documentation](#). The above example URL connects to an Oracle SID named orcl.

Hierarchical Mapping

When mapping Oracle, a Database in Apache Doris corresponds to a User in Oracle. And a Table under a Database in Apache Doris corresponds to a Table accessible by that User in Oracle. The mapping relationship is as follows:

| Doris | Oracle |
|----------|----------|
| Catalog | Database |
| Database | User |
| Table | Table |

Column Type Mapping

| Oracle Type | Doris Type | Comment |
|-----------------------------------|--------------------------------------|---|
| number(P) / number(P, 0) | tinyint/smallint/int/bigint/largeint | Doris will choose the corresponding type based on the size of P: P < 3: TINYINT; P < 5: SMALLINT; P < 10: INT; P < 19: BIGINT; P > 19: LARGEINT |
| number(P, S), if (S > 0 && P > S) | decimal(P, S) | |
| number(P, S), if (S > 0 && P < S) | decimal(S, S) | |
| number(P, S), if (S < 0) | tinyint/smallint/int/bigint/largeint | In the case of S < 0, Doris will set P to P + S , and perform the same mapping as number(P) / number(P, 0) |
| number | | Doris currently does not support the number type without specified P and S |
| decimal(P, S) | decimal(P, S) | |
| float/real | double | |
| date | date | |
| timestamp | datetime(S) | |
| char/nchar | string | |
| varchar2/nvarchar2 | string | |
| long/raw/long raw/internal | string | |
| BLOB | varbinary | Controlled by the enable.mapping.varbinary property of Catalog (supported since 4.0.2). The default is false, which maps to string; when true, it maps to varbinary type. |
| other | UNSUPPORTED | |

Common Issues

1. ONS configuration failed occurs when creating or querying Oracle Catalog

Add -Doracle.jdbc.fanEnabled=false to JAVA_OPTS in be.conf and upgrade the driver to <https://repo1.maven.org/maven2/com/oracle/database/jdbc/ojdbc8/19.23.0.0/ojdbc8-19.23.0.0.jar>

2. Non supported character set (add orai18n.jar in your classpath): ZHS16GBK exception occurs when creating or querying Oracle Catalog

Download [orai18n.jar](#) and place it in the custom_lib/ directory under each FE and BE (create manually if it does not exist) and restart each FE and BE.

SQL Server JDBC Catalog

Doris JDBC Catalog supports connecting to SQL Server databases through the standard JDBC interface. This document describes how to configure the SQL Server database connection.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to a SQL Server database, you need

- SQL Server 2012 or later, or Azure SQL Database.
- JDBC driver for SQL Server database, which you can download the latest or specified version from [Maven Repository](#). It is recommended to use SQL Server JDBC Driver 11.2.x and above.
- Network connection between each FE and BE node of Doris and the SQL Server server, with the default port being 1433.

Connecting to SQL Server

```
CREATE CATALOG sqlserver_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password' = 'pwddd',  
  'jdbc_url' = 'jdbc:sqlserver://<host>:<port>;databaseName=<databaseName>;encrypt=false',  
  'driver_url' = 'mssql-jdbc-11.2.3.jre8.jar',  
  'driver_class' = 'com.microsoft.sqlserver.jdbc.SQLServerDriver'  
)
```

`jdbc_url` defines the connection information and parameters to be passed to the SQL Server JDBC driver. The parameters supported by the URL are provided in the [SQL Server JDBC Driver Documentation](#).

Connection Security

The JDBC driver and connector automatically use Transport Layer Security (TLS) encryption and certificate verification. This requires configuring appropriate TLS certificates on the SQL Server database host.

If you have not established the necessary configuration, you can disable encryption in the connection string using the `encrypt` property:

```
'jdbc_url' = 'jdbc:sqlserver://<host>:<port>;databaseName=<databaseName>;encrypt=false'
```

The TLS section of the [SQL Server JDBC Driver Documentation](#) details other parameters such as `trustServerCertificate`, `hostNameInCertificate`, `trustStore`, and `trustStorePassword`.

Hierarchical Mapping

When mapping SQLServer, a Database in Doris corresponds to a Schema under the specified Database in SQL Server (<databaseName> parameter in jdbc_url). A Table under a Database in Doris corresponds to Tables under a Schema in SQLServer. The mapping relationship is as follows:

| Doris | SQL Server |
|----------|------------|
| Catalog | Database |
| Database | Schema |
| Table | Table |

Column Type Mapping

| SQL Server Type | Doris Type | Comment |
|---------------------------------------|---------------|---|
| bit | boolean | |
| tinyint | smallint | SQLServer's tinyint is unsigned, so it is mapped to Doris's smallint |
| smallint | smallint | |
| int | int | |
| bigint | bigint | |
| real | float | |
| float | double | |
| money | decimal(19,4) | |
| smallmoney | decimal(10,4) | |
| decimal(P, S)/numeric(P, S) | decimal(P, S) | |
| date | date | |
| datetime/datetime2/smalldatetime | datetime(S) | |
| char/varchar/text/nchar/nvarchar/text | string | |
| time/datetimeoffset | string | |
| timestamp | string | Displays hexadecimal representation of binary data, no actual meaning |
| image/binary/varbinary | varbinary | Controlled by the enable.mapping.varbinary property of Catalog (supported since 4.0.2). The default is false, which maps to string; when true, it maps to varbinary type. |
| other | UNSUPPORTED | |

Common Issues

1. Certificate authentication exception when connecting to SQL Server

```
SQLException: The driver could not establish a secure connection to SQL Server by using Secure Sockets Layer (SSL) encryption.  
Error: "sun.security.validator.ValidatorException: PKIX path building failed:  
sun.security.provider.certpath.SunCertPathBuilderException:  
unable to find valid certification path to requested target". ClientConnectionId:a92f3817-e8e6-4311-bc21-7c66
```

You can add `encrypt=false` to the end of the JDBC connection string when creating the Catalog, such as `"jdbc_url" = "jdbc:sqlserver://127.0.0.1:1433;DataBaseName=doris_test;encrypt=false"`

2. TLS exception when connecting to SQL Server

```
The server selected protocol version TLS10 is not accepted by client preferences [TLS13, TLS12]
```

This is because the TLS protocol version between SQL Server and the JDBC client does not match. The connected SQL Server only supports TLS 1.0, while the JAVA environment where the JDBC client is located has TLS 1.0 disabled by default.

The solution is as follows:

1. Enable TLS 1.2 on SQL Server. Refer to: [SQL Server TLS 1.2 Support](#)
2. Enable TLS 1.0 for JDK.

```
vim ${JAVA_HOME}/lib/security/java.security  
# Find this section  
jdk.tls.disabledAlgorithms=SSLv3, TLSv1, TLSv1.1, RC4, DES, MD5withRSA, \  
DH keySize < 1024, EC keySize < 224, 3DES_EDE_CBC, anon, NULL, \  
include jdk.disabled.namedCurves  
  
# Remove TLSv1, TLSv1.1, change it to the following  
jdk.tls.disabledAlgorithms=SSLv3, RC4, DES, MD5withRSA, \  
DH keySize < 1024, EC keySize < 224, anon, NULL, \  
include jdk.disabled.namedCurves
```

IBM Db2 JDBC Catalog

The Doris JDBC Catalog supports connecting to IBM Db2 databases through the standard JDBC interface. This document describes how to configure the IBM Db2 database connection.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to an IBM Db2 database, you need:

- IBM Db2 11.5.x or higher
- The JDBC driver for the IBM Db2 database, which you can download from the [Maven Repository](#) for the latest or specified version of the IBM Db2 driver. It is recommended to use IBM db2 jcc version 11.5.8.0.
- Network connection between each Doris FE and BE node and the IBM Db2 server, with the default port being 51000.

Connecting to IBM Db2

```
CREATE CATALOG db2_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'USERNAME',  
  'password' = 'PASSWORD',  
  'jdbc_url' = 'jdbc:db2://host:port/database',  
  'driver_url' = 'jcc-11.5.8.0.jar',  
  'driver_class' = 'com.ibm.db2.jcc.DB2Driver'  
)
```

The `jdbc_url` defines the connection information and parameters to be passed to the IBM Db2 driver. Supported URL parameters can be found in the [Db2 JDBC Driver Documentation](#).

Hierarchical Mapping

When mapping IBM Db2, Doris's Database corresponds to a Schema under the specified DataBase in DB2 (the "database" parameter in `jdbc_url`). And the Table under Doris's Database corresponds to the Tables under the Schema in DB2. The mapping relationship is as follows:

| Doris | IBM Db2 |
|----------|----------|
| Catalog | DataBase |
| Database | Schema |
| Table | Table |

Column Type Mapping

| IBM Db2 Type | Doris Type | Comment |
|------------------|---------------|--|
| smallint | smallint | |
| int | int | |
| bigint | bigint | |
| double | double | |
| double precision | double | |
| float | double | |
| real | float | |
| decimal(P, S) | decimal(P, S) | |
| decfloat(P, S) | decimal(P, S) | |
| date | date | |
| timestamp(S) | datetime(S) | |
| char(N) | char(N) | |
| varchar(N) | varchar(N) | |
| long varchar(N) | varchar(N) | |
| vargraphic | string | |
| long vargraphic | string | |
| time | string | |
| clob | string | |
| xml | string | |
| BLOB | varbinary | Controlled by the <code>enable.mapping.varbinary</code> property of Catalog (supported since 4.0.2). The default is false, which maps to string; when true, it maps to varbinary type. |
| other | UNSUPPORTED | |

Common Issues

1. When reading IBM Db2 data through JDBC Catalog, an `Invalid operation: result set is closed`. `ERRORCODE=-4470` exception occurs.

Add connection parameters to the `jdbc_url` connection string when creating the IBM Db2 Catalog:
`allowNextOnExhaustedResultSet=1;resultSetHoldability=1;` For example:

```
jdbc:db2://host:port/database:allowNextOnExhaustedResultSet=1;resultSetHoldability=1;
```

.

2. Caught java.io.CharConversionException

This issue may be caused by a character set problem. You can try adding the configuration – `Ddb2.jcc.charsetDecoderEncoder=3` to the `JAVA_OPTS` in `be.conf`, then restart the BE to see if it resolves the issue. You may also experiment with values such as 1 or 2. For more details, please refer to: <https://www.ibm.com/docs/en/content-collector/4.0.1?topic=manager-jdbc-throws-javaiocharconversionexception>

Clickhouse JDBC Catalog

The Doris JDBC Catalog supports connecting to the ClickHouse database via the standard JDBC interface. This document describes how to configure the ClickHouse database connection.

For an overview of the JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to the ClickHouse database, you need

- ClickHouse version 23.x or higher (versions below this have not been fully tested).
- The JDBC driver for the ClickHouse database, which you can download from the [Maven Repository](#) for the latest or specified version of the ClickHouse JDBC driver. It is recommended to use version 0.4.6 of the ClickHouse JDBC Driver.
- Network connection between each FE and BE node of Doris and the ClickHouse server, with the default port being 8123.

Connecting to ClickHouse

```
CREATE CATALOG clickhouse PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password' = 'pwd',  
  'jdbc_url' = 'jdbc:clickhouse://example.net:8123/',  
  'driver_url' = 'clickhouse-jdbc-0.4.6-all.jar',  
  'driver_class' = 'com.clickhouse.jdbc.ClickHouseDriver'  
)
```

The `jdbc_url` defines the connection information and parameters to be passed to the ClickHouse JDBC driver. Supported URL parameters can be found in the [ClickHouse JDBC Driver Configuration](#).

Connection Security

If you have configured TLS with a globally trusted certificate installed on the data source, you can enable TLS between the cluster and the data source by appending parameters to the JDBC connection string set in the `jdbc_url` property.

For example, enable TLS by adding the `ssl=true` parameter to the `jdbc_url` configuration property:

```
'jdbc_url' = 'jdbc:clickhouse://example.net:8123/db?ssl=true'
```

For more information on TLS configuration options, please refer to the [Clickhouse JDBC Driver Documentation SSL Configuration Section](#)

Hierarchical Mapping

When mapping ClickHouse, a Database in Doris corresponds to a Database in ClickHouse. And a Table under a Database in Doris corresponds to Tables under that Database in ClickHouse. The mapping relationship is as follows:

| Doris | ClickHouse |
|----------|-------------------|
| Catalog | ClickHouse Server |
| Database | Database |
| Table | Table |

Column Type Mapping

| ClickHouse Type | Doris Type | Comment |
|---------------------------|-------------------------|---|
| bool | boolean | |
| string | string | |
| date/date32 | date | |
| datetime(S)/datetime64(S) | datetime(S) | |
| float32 | float | |
| float64 | double | |
| int8 | tinyint | |
| int16/uint8 | smallint | Doris does not have UNSIGNED data types, so it is scaled up by one magnitude |
| int32/uint16 | int | Same as above |
| int64/uint32 | bigint | Same as above |
| int128/uint64 | largeint | Same as above |
| int256/uint128/uint256 | string | Doris does not have data types of this magnitude, so it is handled with STRING |
| decimal(P, S) | decimal(P, S) or string | If it exceeds the maximum precision supported by Doris, use string to handle it |
| enum/ipv4/ipv6/uuid | string | |
| array | array | |
| other | UNSUPPORTED | |

Related Parameters

- `jdbc_clickhouse_query_final`

Session variable, default is false. When set to true, `SETTINGS final = 1` will be appended to the SQL statements sent to Clickhouse.

Common Issues

1. Encountering `NoClassDefFoundError: net/jpountz/lz4/LZ4Factory` error message when reading Clickhouse data

You can first download the [lz4-1.3.0.jar](#) package and place it in the `custom_lib/` directory under each FE and BE directory (if it does not exist, create it manually).

SAP HANA JDBC Catalog

The Doris JDBC Catalog supports connecting to the SAP HANA database through the standard JDBC interface. This document describes how to configure the SAP HANA database connection.

For an overview of the JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to the SAP HANA database, you need

- SAP HANA 2.0 or higher.
- The JDBC driver for the SAP HANA database, which you can download from the [Maven Repository](#). It is recommended to use version ngdbc 2.4.51 or above.
- Network connection between each Doris FE and BE node and the SAP HANA server, with the default port being 30015.

Connecting to SAP HANA

```
CREATE CATALOG saphana_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password' = 'pwd',  
  'jdbc_url' = 'jdbc:sap://Hostname:Port/?optionalparameters',  
  'driver_url' = 'ngdbc-2.4.51.jar',  
  'driver_class' = 'com.sap.db.jdbc.Driver'  
)
```

For more information on the JDBC URL format and parameters supported by the SAP HANA JDBC driver, please refer to [SAP HANA](#).

Hierarchical Mapping

When mapping SAP HANA, the Database in Doris corresponds to a Schema under the specified DataBase in SAP HANA (the “DATABASE” in the `jdbc_url` parameter). The Table under the Database in Doris corresponds to the Tables under the Schema in SAP HANA. The mapping relationship is as follows:

| Doris | SAP HANA |
|----------|----------|
| Catalog | Database |
| Database | Schema |
| Table | Table |

Column Type Mapping

| SAP HANA Type | Doris Type | Comment |
|--------------------|-----------------------------------|---|
| boolean | boolean | |
| tinyint | tinyint | |
| smallint | smallint | |
| integer | int | |
| bigint | bigint | |
| smalldecimal(P, S) | decimal(P, S) or double or string | If precision is not specified, the double type is used. If the precision exceeds the maximum precision supported by Doris, the string type is used. |
| decimal(P, S) | decimal(P, S) or double or string | Same as above. |
| real | float | |
| double | double | |
| date | date | |
| time | string | |
| timestamp(S) | datetime(S) | |
| seconddate | datetime(S) | |
| varchar | string | |
| nvarchar | string | |
| alphanum | string | |
| shorttext | string | |
| char(N) | char(N) | |
| nchar(N) | char(N) | |
| other | UNSUPPORTED | |

Oceanbase JDBC Catalog

Doris JDBC Catalog supports connecting to OceanBase database through the standard JDBC interface. This document describes how to configure the OceanBase database connection.

For an overview of JDBC Catalog, please refer to: [JDBC Catalog Overview](#)

Usage Notes

To connect to the OceanBase database, you need

- OceanBase 3.1.0 or higher
- JDBC driver for OceanBase database, which you can download the latest or specified version of OceanBase JDBC driver from [Maven Repository](#). It is recommended to use OceanBase Connector/J 2.4.8 or above.
- Network connection between each FE and BE node of Doris and the OceanBase server.

Connect to OceanBase

```
CREATE CATALOG oceanbase_catalog PROPERTIES (  
  'type' = 'jdbc',  
  'user' = 'username',  
  'password' = 'pwd',  
  'jdbc_url' = 'jdbc:oceanbase://host:port/db',  
  'driver_url' = 'oceanbase-client-2.4.8.jar',  
  'driver_class' = 'com.oceanbase.jdbc.Driver'  
)
```

`jdbc_url` defines the connection information and parameters to be passed to the OceanBase JDBC driver. Supported URL parameters can be found in [OceanBase JDBC Driver Configuration](#).

Schema Compatibility

When creating an OceanBase Catalog, Doris will automatically recognize whether OceanBase is in MySQL or Oracle mode to correctly parse metadata.

The hierarchy mapping, type mapping, and query optimization in different modes are handled in the same way as the Catalog of MySQL or Oracle databases, and you can refer to the documentation

- [MySQL Catalog](#)
- [Oracle Catalog](#)

Analyze Files on S3/HDFS

Through the Table Value Function feature, Doris can directly query and analyze files on object storage or HDFS as a Table. It also supports automatic column type inference.

For more usage methods, refer to the Table Value Function documentation:

- [S3](#): Supports file analysis on S3-compatible object storage.
- [HDFS](#): Supports file analysis on HDFS.

Basic Usage

Here we illustrate how to analyze files on object storage using the S3 Table Value Function as an example.

Query

```
SELECT * FROM S3 (  
  'uri' = 's3://bucket/path/to/tvf_test/test.parquet',  
  'format' = 'parquet',  
  's3.endpoint' = 'https://s3.us-east-1.amazonaws.com',  
  's3.region' = 'us-east-1',  
  's3.access_key' = 'ak',  
  's3.secret_key' = 'sk'  
)
```

The S3(...) is a TVF (Table Value Function). A Table Value Function is essentially a table, so it can appear in any SQL statement where a “table” can appear.

The attributes of a TVF include the file path to be analyzed, file format, connection information of the object storage, etc. The file path (URI) can use wildcards to match multiple files. The following file paths are valid:

- Match a specific file
`s3://bucket/path/to/tvf_test/test.parquet`
- Match all files starting with test_
`s3://bucket/path/to/tvf_test/test_*`
- Match all files with the .parquet suffix
`s3://bucket/path/to/tvf_test/*.parquet`
- Match all files in the tvf_test directory
`s3://bucket/path/to/tvf_test/*`
- Match files with test in the filename
`s3://bucket/path/to/tvf_test/*test*`

Automatic Inference of File Column Types

You can view the Schema of a TVF using the DESC FUNCTION syntax:

```
DESC FUNCTION s3 (
  "URI" = "s3://bucket/path/to/tvf_test/test.parquet",
  "s3.access_key"= "ak",
  "s3.secret_key" = "sk",
  "format" = "parquet",
  "use_path_style"="true"
);
```

| Field | Type | Null | Key | Default | Extra |
|---------------|--------------|------|-------|---------|-------|
| p_partkey | INT | Yes | false | NULL | NONE |
| p_name | TEXT | Yes | false | NULL | NONE |
| p_mfgr | TEXT | Yes | false | NULL | NONE |
| p_brand | TEXT | Yes | false | NULL | NONE |
| p_type | TEXT | Yes | false | NULL | NONE |
| p_size | INT | Yes | false | NULL | NONE |
| p_container | TEXT | Yes | false | NULL | NONE |
| p_retailprice | DECIMAL(9,0) | Yes | false | NULL | NONE |
| p_comment | TEXT | Yes | false | NULL | NONE |

Doris infers the Schema based on the following rules:

- For Parquet and ORC formats, Doris obtains the Schema from the file metadata.
- In the case of matching multiple files, the Schema of the first file is used as the TVF's Schema.
- For CSV and JSON formats, Doris parses the **first line of data** to obtain the Schema based on fields, delimiters, etc.

By default, all column types are string. You can specify column names and types individually using the csv_schema attribute. Doris will use the specified column types for file reading. The format is: name1:type1;name2:type2;... For example:

```
S3 (
  'uri' = 's3://bucket/path/to/tvf_test/test.parquet',
  's3.endpoint' = 'https://s3.us-east-1.amazonaws.com',
  's3.region' = 'us-east-1',
  's3.access_key' = 'ak',
  's3.secret_key'='sk',
  'format' = 'csv',
  'column_separator' = '|',
  'csv_schema' = 'k1:int;k2:int;k3:int;k4:decimal(38,10)'
)
```

The currently supported column type names are as follows:

| Column Type Name |
|------------------|
| tinyint |
| smallint |
| int |

| Column Type Name |
|------------------|
| bigint |
| largeint |
| float |
| double |
| decimal(p,s) |
| date |
| datetime |
| char |
| varchar |
| string |
| boolean |

- For columns with mismatched formats (e.g., the file contains a string, but the user defines it as int; or other files have a different Schema than the first file), or missing columns (e.g., the file has 4 columns, but the user defines 5 columns), these columns will return null.

Applicable Scenarios

Query Analysis

TVF is very suitable for directly analyzing independent files on storage systems without having to import the data into Doris in advance.

You can use any SQL statement for file analysis, such as:

```
SELECT * FROM s3(
  'uri' = 's3://bucket/path/to/tvf_test/test.parquet',
  'format' = 'parquet',
  's3.endpoint' = 'https://s3.us-east-1.amazonaws.com',
  's3.region' = 'us-east-1',
  's3.access_key' = 'ak',
  's3.secret_key'='sk'
)
ORDER BY p_partkey LIMIT 5;
```

| p_partkey | p_name | p_mfgr | p_brand | p_type |
|-----------|--|----------------|----------|-------------------------|
| 1 | goldenrod lavender spring chocolate lace | Manufacturer#1 | Brand#13 | PROMO BURNISHED COPPER |
| 7 | JUMBO PKG 901 ly. slyly ironi | | | |
| 2 | blush thistle blue yellow saddle | Manufacturer#1 | Brand#13 | LARGE BRUSHED BRASS |
| 1 | LG CASE 902 lar accounts amo | | | |
| 3 | spring green yellow purple cornsilk | Manufacturer#4 | Brand#42 | STANDARD POLISHED BRASS |
| 21 | WRAP CASE 903 egular deposits hag | | | |
| 4 | cornflower chocolate smoke green pink | Manufacturer#3 | Brand#34 | SMALL PLATED BRASS |
| 14 | MED DRUM 904 p furiously r | | | |
| 5 | forest brown coral puff cream | Manufacturer#3 | Brand#32 | STANDARD POLISHED TIN |

Notes

1. If the specified `uri` does not match any files, or all matched files are empty, the TVF will return an empty result set. In this case, using `DESC FUNCTION` to view the Schema of this TVF will yield a virtual column `__dummy_col`, which is meaningless and only serves as a placeholder.
2. If the specified file format is `csv`, and the file read is not empty but the first line of the file is empty, an error `The first line is empty, can not parse column numbers` will be prompted, as the Schema cannot be parsed from the first line of the file.

Hive Metastore

This document describes all supported parameters when connecting to and accessing Hive MetaStore services through the CREATE CATALOG statement.

Supported Catalog Types

| Catalog Type | Type Identifier (type) | Description |
|--------------|------------------------|--|
| Hive | hms | Catalog for connecting to Hive Metastore |
| Iceberg | iceberg | Catalog for Iceberg table format |
| Paimon | paimon | Catalog for Apache Paimon table format |

Common Parameters Overview

The following parameters are common to different Catalog types.

| Parameter Name | Former Name | Required | Description |
|------------------------------------|-----------------------------------|----------|---|
| hive.metastore.uris | | Yes | URI address of Hive Metastore, supports multiple URIs separated by commas. Example: 'hive.metastore.uris' = 'thrift://127.0.0.1:9083','hive.metastore.uris' = 'thrift://127.0.0.1:9083,thrift://127.0.0.1:9084' |
| hive.metastore.authentication.type | hadoop.security.authentication | No | Metastore authentication method: supports simple (default) or kerberos. In versions 3.0 and earlier, authentication method was determined by hadoop.security.authentication property. Starting from version 3.1, Hive Metastore authentication method can be specified separately. Example: 'hive.metastore.authentication.type' = 'kerberos' |
| hive.metastore.service.principal | hive.metastore.kerberos.principal | No | Hive server principal, supports _HOST placeholder. Example: 'hive.metastore.service.principal' = 'hive/_HOST@EXAMPLE.COM' |
| hive.metastore.client.principal | hadoop.kerberos.principal | No | Kerberos principal used by Doris to connect to Hive MetaStore service. |

Note:

For versions before 3.1.0, please use the former names.

Required Parameters

- `hive.metastore.uris`: Must specify the URI address of Hive Metastore

Optional Parameters

- `hive.metastore.authentication.type`: Authentication method, default is `simple`, optional `kerberos`
- `hive.metastore.service.principal`: Kerberos principal of Hive MetaStore service, must be specified when using Kerberos authentication.
- `hive.metastore.client.principal`: Kerberos principal used by Doris to connect to Hive MetaStore service, must be specified when using Kerberos authentication.
- `hive.metastore.client.keytab`: Kerberos keytab file path, must be specified when using Kerberos authentication.
- `hive.metastore.username`: Username for connecting to Hive MetaStore service, used in non-Kerberos mode, default is `hadoop`.
- `hive.conf.resources`: `hive-site.xml` configuration file path, used when configuration for connecting to Hive Metastore service needs to be read from configuration files.

Authentication Methods

Simple Authentication

- `simple`: Non-Kerberos mode, directly connects to Hive Metastore service.

Kerberos Authentication

To use Kerberos authentication to connect to Hive Metastore service, configure the following parameters:

- `hive.metastore.authentication.type`: Set to `kerberos`
- `hive.metastore.service.principal`: Kerberos principal of Hive MetaStore service
- `hive.metastore.client.principal`: Kerberos principal used by Doris to connect to Hive MetaStore service
- `hive.metastore.client.keytab`: Kerberos keytab file path

```
'hive.metastore.authentication.type' = 'kerberos',  
'hive.metastore.service.principal' = 'hive/_HOST@EXAMPLE.COM',  
'hive.metastore.client.principal' = 'hive/doris.cluster@EXAMPLE.COM',  
'hive.metastore.client.keytab' = '/etc/security/keytabs/hive.keytab'
```

When using Hive MetaStore service with Kerberos authentication enabled, ensure that the same keytab file exists on all FE nodes, the user running the Doris process has read permission to the keytab file, and the krb5 configuration file is properly configured.

For detailed Kerberos configuration, refer to Kerberos Authentication.

Configuration File Parameters

`hive.conf.resources`

If you need to read configuration for connecting to Hive Metastore service through configuration files, you can configure the `hive.conf.resources` parameter to set the conf file path.

Note: The `hive.conf.resources` parameter only supports relative paths, do not use absolute paths. The default path is under the `${DORIS_HOME}/plugins/hadoop_conf/` directory. You can specify other directories by modifying `hadoop_config_dir` in `fe.conf`.

Example: `'hive.conf.resources' = 'hms-1/hive-site.xml'`

Catalog Type-Specific Data

The following parameters are specific to each Catalog type, in addition to the common parameters.

Hive Catalog

| Parameter Name | Former Name | Required | Default | Description |
|----------------------------------|-------------|----------|--------------------|--|
| <code>type</code> | | Yes | None | Catalog type, fixed as <code>hms</code> for Hive Catalog |
| <code>hive.metastore.type</code> | | No | <code>'hms'</code> | Metadata Catalog type, fixed as <code>hms</code> for Hive Metastore, must be <code>hms</code> when using HiveMetaStore |

Examples

1. Create a Hive Catalog using unauthenticated Hive Metastore as metadata service, with S3 storage service.

```
CREATE CATALOG hive_hms_s3_test_catalog PROPERTIES (  
  'type' = 'hms',  
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',  
  's3.access_key' = 'S3_ACCESS_KEY',  
  's3.secret_key' = 'S3_SECRET_KEY',  
  's3.region' = 's3.ap-east-1.amazonaws.com'  
);
```

2. Create a Hive Catalog using Hive Metastore with Kerberos authentication enabled as metadata service, with S3 storage service.

```
CREATE CATALOG hive_hms_on_oss_kerberos_new_catalog PROPERTIES (
  'type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
  'hive.metastore.client.principal'='hive/presto-master.docker.cluster@LABS.TERADATA.COM',
  'hive.metastore.client.keytab' = '/mnt/keytabs/hive-presto-master.keytab',
  'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
  'hive.metastore.authentication.type'='kerberos',
  'hadoop.security.auth_to_local' = 'RULE: [2:\$1@\$0](.*@LABS.TERADATA.COM)s/@.*//
                                RULE: [2:\$1@\$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
                                RULE: [2:\$1@\$0](.*@OTHERREALM.COM)s/@.*//
                                DEFAULT',
  'oss.access_key' = 'OSS_ACCESS_KEY',
  'oss.secret_key' = 'OSS_SECRET_KEY',
  'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com'
);
```

Iceberg Catalog

| Parameter Name | Former Name | Required | Default | Description |
|----------------------|-------------|----------|---------|--|
| type | | Yes | None | Catalog type, fixed as iceberg for Iceberg |
| iceberg.catalog.type | | No | None | Metadata Catalog type, fixed as hms for Hive Metastore, must be hms when using HiveMetaStore |
| warehouse | | No | None | Iceberg warehouse path |

Examples

1. Create an Iceberg Catalog using Hive Metastore as metadata service, with S3 storage service.

```
CREATE CATALOG iceberg_hms_s3_test_catalog PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
  'warehouse' = 's3://doris/iceberg_warehouse/',
  's3.access_key' = 'S3_ACCESS_KEY',
  's3.secret_key' = 'S3_SECRET_KEY',
  's3.region' = 's3.ap-east-1.amazonaws.com'
);
```

2. Create an Iceberg Catalog using Hive Metastore with Kerberos authentication enabled as metadata service in a multi-Kerberos environment, with S3 storage service.

```
CREATE CATALOG IF NOT EXISTS iceberg_hms_on_oss_kerberos_new_catalog PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'hms',
  'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
  'warehouse' = 'oss://doris/iceberg_warehouse/',
  'hive.metastore.client.principal'='hive/presto-master.docker.cluster@LABS.TERADATA.COM',
  'hive.metastore.client.keytab' = '/mnt/keytabs/hive-presto-master.keytab',
  'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
  'hive.metastore.authentication.type'='kerberos',
  'hadoop.security.auth_to_local' = 'RULE: [2:\$1@\$0](.*@LABS.TERADATA.COM)s/@.*//
                                RULE: [2:\$1@\$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
                                RULE: [2:\$1@\$0](.*@OTHERREALM.COM)s/@.*//
```

```

        DEFAULT',
        'oss.access_key' = 'OSS_ACCESS_KEY',
        'oss.secret_key' = 'OSS_SECRET_KEY',
        'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com'
    );

```

Paimon Catalog

| Parameter Name | Former Name | Required | Default | Description |
|---------------------|-------------|----------|------------|--|
| type | | Yes | None | Catalog type, fixed as paimon for Paimon |
| paimon.catalog.type | | No | filesystem | Must be hms when using HiveMetaStore, default is filesystem for storing metadata in filesystem |
| warehouse | | Yes | None | Paimon warehouse path |

Examples

1. Create a Paimon Catalog using Hive Metastore as metadata service, with S3 storage service.

```

CREATE CATALOG IF NOT EXISTS paimon_hms_s3_test_catalog PROPERTIES (
    'type' = 'paimon',
    'paimon.catalog.type' = 'hms',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9383',
    'warehouse' = 's3://doris/paimon_warehouse/',
    's3.access_key' = 'S3_ACCESS_KEY',
    's3.secret_key' = 'S3_SECRET_KEY',
    's3.region' = 's3.ap-east-1.amazonaws.com'
);

```

2. Create a Paimon Catalog using Hive Metastore with Kerberos authentication enabled as metadata service in a multi-Kerberos environment, with S3 storage service.

```

CREATE CATALOG IF NOT EXISTS paimon_hms_on_oss_kerberos_new_catalog PROPERTIES (
    'type' = 'paimon',
    'paimon.catalog.type' = 'hms',
    'hive.metastore.uris' = 'thrift://127.0.0.1:9583',
    'warehouse' = 's3://doris/iceberg_warehouse/',
    'hive.metastore.client.principal'='hive/presto-master.docker.cluster@LABS.TERADATA.COM',
    'hive.metastore.client.keytab' = '/mnt/keytabs/hive-presto-master.keytab',
    'hive.metastore.service.principal' = 'hive/hadoop-master@LABS.TERADATA.COM',
    'hive.metastore.authentication.type'='kerberos',
    'hadoop.security.auth_to_local' = 'RULE: [2:\$1@\$0](.*@LABS.TERADATA.COM)s/@.*//
        RULE: [2:\$1@\$0](.*@OTHERLABS.TERADATA.COM)s/@.*//
        RULE: [2:\$1@\$0](.*@OTHERREALM.COM)s/@.*//
        DEFAULT',
    'oss.access_key' = 'OSS_ACCESS_KEY',
    'oss.secret_key' = 'OSS_SECRET_KEY',
    'oss.endpoint' = 'oss-cn-beijing.aliyuncs.com'
);

```

HMS Access Port Requirements

Doris requires at least the following ports to be open to access HMS:

| Service | Port Purpose | Default Port | Protocol |
|----------------|--------------------------|--------------|----------|
| Hive Metastore | Thrift (metadata access) | 9083 | TCP |

Notes: - Ports may be customized in `hive-site.xml`. Always follow your actual configuration. - When Kerberos authentication is enabled, ensure network connectivity from Doris to the Kerberos KDC. The KDC listens on TCP port 88 by default, unless customized in your KDC configuration.

Frequently Asked Questions (FAQ)

- Q1: Is `hive-site.xml` mandatory?

No, it's only used when configuration needs to be read from it.

- Q2: Must the keytab file exist on every node?

Yes, all FE nodes must be able to access the specified path.

- Q3: What should be noted when using write-back functionality, i.e., creating Hive/Iceberg databases/tables in Doris?

Since creating tables involves metadata operations on the storage side, i.e., accessing the storage system, the Hive MetaStore service server side needs to configure corresponding storage parameters, such as access parameters for S3, OSS and other storage services. When using object storage as the underlying storage system, ensure that the bucket being written to matches the configured Region.

AWS Glue

This document describes the parameter configuration when using **AWS Glue Catalog** to access **Iceberg tables** or **Hive tables** through CREATE CATALOG.

Supported Glue Catalog Types

AWS Glue Catalog currently supports three types of Catalogs:

| Catalog Type | Type Identifier (type) | Description |
|--------------|------------------------|--|
| Hive | glue | Catalog for connecting to Hive Metastore |
| Iceberg | glue | Catalog for connecting to Iceberg table format |
| Iceberg | rest | Catalog for connecting to Iceberg table format via Glue Rest Catalog |

This documentation provides detailed parameter descriptions for each type to facilitate user configuration.

Common Parameters Overview

| Parameter Name | Description | Required | Default Value |
|------------------|---|----------|---------------|
| glue.region | AWS Glue region, e.g., us-east-1 | Yes | None |
| glue.endpoint | AWS Glue endpoint, e.g., https://glue.us-east-1.amazonaws.com | Yes | None |
| glue.access_key | AWS Access Key ID | Yes | Empty |
| glue.secret_key | AWS Secret Access Key | Yes | Empty |
| glue.catalog_id | Glue Catalog ID (not supported yet) | No | Empty |
| glue.role_arn | IAM Role ARN for accessing Glue (supported since 3.1.2+) | No | Empty |
| glue.external_id | IAM External ID for accessing Glue (supported since 3.1.2+) | No | Empty |

Authentication Parameters

Accessing Glue requires authentication information, supporting the following two methods:

1. Access Key Authentication

Authenticate access to Glue through Access Key provided by glue.access_key and glue.secret_key.

2. IAM Role Authentication (supported since 3.1.2+)

Authenticate access to Glue through IAM Role provided by glue.role_arn.

This method requires Doris to be deployed on AWS EC2, and the EC2 instance needs to be bound to an IAM Role that has permission to access Glue.

If access through External ID is required, you need to configure `glue.external_id` as well.

Notes:

- At least one of the two methods must be configured. If both methods are configured, Access Key authentication takes priority.

Example:

```
```sql
CREATE CATALOG hive_glue_catalog PROPERTIES (
 'type' = 'hms',
 'hive.metastore.type' = 'glue',
 'glue.region' = 'us-east-1',
 'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
 -- Using Access Key authentication
 'glue.access_key' = '<YOUR_ACCESS_KEY>',
 'glue.secret_key' = '<YOUR_SECRET_KEY>'
 -- Or using IAM Role authentication
 -- 'glue.role_arn' = '<YOUR_ROLE_ARN>',
 -- 'glue.external_id' = '<YOUR_EXTERNAL_ID>'
);
```
```

Hive Glue Catalog

Hive Glue Catalog is used to access Hive tables through AWS Glue's Hive Metastore compatible interface. Configuration as follows:

| Parameter Name | Description | Required | Default Value |
|---------------------|---|----------|---------------|
| type | Fixed as hms | Yes | None |
| hive.metastore.type | Fixed as glue | Yes | None |
| glue.region | AWS Glue region, e.g., us-east-1 | Yes | None |
| glue.endpoint | AWS Glue endpoint, e.g., https://glue.us-east-1.amazonaws.com | Yes | None |
| glue.access_key | AWS Access Key ID | No | Empty |
| glue.secret_key | AWS Secret Access Key | No | Empty |
| glue.catalog_id | Glue Catalog ID (not supported yet) | No | Empty |
| glue.role_arn | IAM Role ARN for accessing Glue | No | Empty |
| glue.external_id | IAM External ID for accessing Glue | No | Empty |

Example

```
CREATE CATALOG hive_glue_catalog PROPERTIES (
  'type' = 'hms',
  'hive.metastore.type' = 'glue',
  'glue.region' = 'us-east-1',
  'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
  'glue.access_key' = 'YOUR_ACCESS_KEY',
```

```
'glue.secret_key' = 'YOUR_SECRET_KEY'
);
```

Iceberg Glue Catalog

Iceberg Glue Catalog accesses Glue through Glue Client. Configuration as follows:

| Parameter Name | Description | Required | Default Value |
|----------------------|--|----------|---------------|
| type | Fixed as iceberg | Yes | None |
| iceberg.catalog.type | Fixed as glue | Yes | None |
| warehouse | Iceberg data warehouse path, e.g., s3://my-bucket/iceberg-warehouse/ | Yes | s3://doris |
| glue.region | AWS Glue region, e.g., us-east-1 | Yes | None |
| glue.endpoint | AWS Glue endpoint, e.g., https://glue.us-east-1.amazonaws.com | Yes | None |
| glue.access_key | AWS Access Key ID | No | Empty |
| glue.secret_key | AWS Secret Access Key | No | Empty |
| glue.catalog_id | Glue Catalog ID (not supported yet) | No | Empty |
| glue.role_arn | IAM Role ARN for accessing Glue (not supported yet) | No | Empty |
| glue.external_id | IAM External ID for accessing Glue (not supported yet) | No | Empty |

Example

```
CREATE CATALOG iceberg_glue_catalog PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'glue',
  'glue.region' = 'us-east-1',
  'glue.endpoint' = 'https://glue.us-east-1.amazonaws.com',
  'glue.access_key' = '<YOUR_ACCESS_KEY>',
  'glue.secret_key' = '<YOUR_SECRET_KEY>'
);
```

Iceberg Glue Rest Catalog

Iceberg Glue Rest Catalog accesses Glue through Glue Rest Catalog interface. Currently only supports Iceberg tables stored in AWS S3 Table Bucket. Configuration as follows:

| Parameter Name | Description | Required | Default Value |
|----------------------|--|----------|---------------|
| type | Fixed as iceberg | Yes | None |
| iceberg.catalog.type | Fixed as rest | Yes | None |
| iceberg.rest.uri | Glue Rest service endpoint, e.g., https://glue.ap-east-1.amazonaws.com/iceberg | Yes | None |
| warehouse | Iceberg data warehouse path, e.g., <account_id>:s3tablescatalog/<bucket_name> | Yes | None |

| Parameter Name | Description | Required | Default Value |
|--------------------------------|---|----------|---------------|
| iceberg.rest.sigv4-enabled | Enable V4 signature format, fixed as true | Yes | None |
| iceberg.rest.signing-name | Signature type, fixed as glue | Yes | Empty |
| iceberg.rest.access-key-id | Access Key for accessing Glue (also used for accessing S3 Bucket) | Yes | Empty |
| iceberg.rest.secret-access-key | Secret Key for accessing Glue (also used for accessing S3 Bucket) | Yes | Empty |
| iceberg.rest.signing-region | AWS Glue region, e.g., us-east-1 | Yes | Empty |

Example

```
CREATE CATALOG glue_s3 PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'https://glue.<region>.amazonaws.com/iceberg',
  'warehouse' = '<account_id>:s3tablescatalog/<s3_table_bucket_name>',
  'iceberg.rest.sigv4-enabled' = 'true',
  'iceberg.rest.signing-name' = 'glue',
  'iceberg.rest.access-key-id' = '<ak>',
  'iceberg.rest.secret-access-key' = '<sk>',
  'iceberg.rest.signing-region' = '<region>'
);
```

Permission Policies

Depending on usage scenarios, they can be divided into **read-only** and **read-write** policies.

1. Read-Only Permissions

Only allows reading database and table information from Glue Catalog.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GlueCatalogReadOnly",
      "Effect": "Allow",
      "Action": [
        "glue:GetCatalog",
        "glue:GetDatabase",
        "glue:GetDatabases",
        "glue:GetTable",
        "glue:GetTables",
        "glue:GetPartitions"
      ],
      "Resource": [
        "arn:aws:glue:<region>:<account-id>:catalog",
        "arn:aws:glue:<region>:<account-id>:database/*",
        "arn:aws:glue:<region>:<account-id>:table/*/*"
      ]
    }
  ]
}
```

```
]
}
```

2. Read-Write Permissions

Based on read-only permissions, allows creating/modifying/deleting databases and tables.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GlueCatalogReadWrite",
      "Effect": "Allow",
      "Action": [
        "glue:GetCatalog",
        "glue:GetDatabase",
        "glue:GetDatabases",
        "glue:GetTable",
        "glue:GetTables",
        "glue:GetPartitions",
        "glue:CreateDatabase",
        "glue:UpdateDatabase",
        "glue>DeleteDatabase",
        "glue:CreateTable",
        "glue:UpdateTable",
        "glue>DeleteTable"
      ],
      "Resource": [
        "arn:aws:glue:<region>:<account-id>:catalog",
        "arn:aws:glue:<region>:<account-id>:database/*",
        "arn:aws:glue:<region>:<account-id>:table/*/*"
      ]
    }
  ]
}
```

Notes

1. Placeholder Replacement

- <region> → Your AWS region (e.g., us-east-1).
- <account-id> → Your AWS account ID (12-digit number).

2. Principle of Least Privilege

- If only querying, do not grant write permissions.
- Can replace * with specific database/table ARNs to further restrict permissions.

3. S3 Permissions

- The above policies only involve Glue Catalog.
- If you need to read data files, additional S3 permissions are required (such as s3:GetObject, s3:ListBucket, etc.).

Google Dataproc

This document describes the supported parameters when connecting to and accessing Google Dataproc Metastore through the CREATE CATALOG statement.

| Property Name | Description | Default Value | Required |
|--------------------|---|---------------|----------|
| hive.metastore.uri | The URI address of the Metastore. Can be obtained from the Dataproc Metastore Services page | None | Yes |

Aliyun DLF

This document describes how to use the CREATE CATALOG statement to connect and access Alibaba Cloud [Data Lake Formation \(DLF\)](#) metadata service.

DLF Version Notes

- For DLF 1.0 version, Doris accesses DLF through DLF's Hive Metastore compatible interface. Supports Paimon Catalog and Hive Catalog.
- For DLF versions 2.5 and later, Doris accesses DLF through DLF's Rest interface. Only supports Paimon Catalog.

DLF 1.0

| Parameter Name | Legacy Name | Description | Default Value | Required |
|----------------|----------------|---|---------------|----------|
| dlf.endpoint | - | DLF endpoint, see: Alibaba Cloud Documentation | None | Yes |
| dlf.region | - | DLF region, see: Alibaba Cloud Documentation | None | Yes |
| dlf.uid | - | Alibaba Cloud account ID. Can be viewed in personal information at the top right corner of the console. | None | Yes |
| dlf.access_key | - | Alibaba Cloud AccessKey for accessing DLF service. | None | Yes |
| dlf.secret_key | - | Alibaba Cloud SecretKey for accessing DLF service. | None | Yes |
| dlf.catalog_id | dlf.catalog.id | Catalog ID. Used to specify metadata catalog. If not set, the default catalog is used. | None | No |
| warehouse | - | Storage path of the Warehouse, only required for Paimon Catalog. Note that the object storage path must end with /. | None | No |

Note:

For versions before 3.1.0, please use the former names.

DLF 2.5+ (Rest Catalog)

Supported since version 3.1.0

| Parameter Name | Legacy Name | Description | Default Value | Required |
|-----------------------------------|-------------|---|---------------|----------|
| uri | - | DLF REST URI.
Example: http://cn-beijing-vpc.dlf.aliyuncs.com | None | Yes |
| warehouse | - | Warehouse name. Note: directly fill in the name of the Catalog to connect to, not the Paimon table storage path | None | Yes |
| paimon.rest.token.provider | - | Token provider, fixed value dlf | None | Yes |
| paimon.rest.dlf.access-key-id | - | Alibaba Cloud AccessKey for accessing DLF service. | None | Yes |
| paimon.rest.dlf.access-key-secret | - | Alibaba Cloud SecretKey for accessing DLF service. | None | Yes |

DLF Rest Catalog does not require providing storage service (OSS) Endpoint and Region information. Doris will use DLF Rest Catalog's Vended Credential to obtain temporary credential information for accessing OSS.

Examples

DLF 1.0

Create a Hive Catalog with DLF as the metadata service:

```
CREATE CATALOG hive_dlf_catalog WITH (  
  'type' = 'hms',  
  'hive.metastore.type' = 'dlf',  
  'dlf.endpoint' = '<DLF_ENDPOINT>',  
  'dlf.region' = '<DLF_REGION>',  
  'dlf.uid' = '<YOUR_ALICLOUD_UID>',  
  'dlf.access_key' = '<YOUR_ACCESS_KEY>',  
  'dlf.secret_key' = '<YOUR_SECRET_KEY>' )  
);
```

Create a Paimon Catalog with DLF as the metadata service:

```
CREATE CATALOG paimon_dlf PROPERTIES (  
  'type' = 'paimon',  
  'paimon.catalog.type' = 'dlf',  
  'warehouse' = 'oss://xx/yy/',  
  'dlf.proxy.mode' = 'DLF_ONLY',  
  'dlf.endpoint' = '<DLF_ENDPOINT>',  
  'dlf.region' = '<DLF_REGION>',  
  'dlf.uid' = '<YOUR_ALICLOUD_UID>',  
  'dlf.access_key' = '<YOUR_ACCESS_KEY>',  
  'dlf.secret_key' = '<YOUR_SECRET_KEY>' )  
;
```

DLF 2.5+ (Rest Catalog)

```
CREATE CATALOG paimon_dlf_test PROPERTIES (  
  'type' = 'paimon',  
  'paimon.catalog.type' = 'rest',  
  'uri' = 'http://cn-beijing-vpc.dlf.aliyuncs.com',  
  'warehouse' = 'my_catalog_name',  
  'paimon.rest.token.provider' = 'dlf',  
  'paimon.rest.dlf.access-key-id' = '<YOUR_ACCESS_KEY>',  
  'paimon.rest.dlf.access-key-secret' = '<YOUR_SECRET_KEY>' )  
;
```

Iceberg Rest Catalog API

This document describes the supported parameters when connecting to and accessing metadata services that support the Iceberg Rest Catalog interface through the `CREATE CATALOG` statement.

Parameter Overview

| Property Name | Legacy Name | Description | Default Value | Required |
|---|-------------|---|---------------|----------|
| iceberg.rest.uri | uri | Specifies the Rest service address | - | Yes |
| warehouse | warehouse | Specifies the iceberg warehouse | - | Yes |
| iceberg.rest.security.type | | Specifies the Rest service authentication method, supports oauth2, defaults to none (no authentication) | none | No |
| iceberg.rest.oauth2.token | | Bearer token when using oauth2 authentication | - | No |
| iceberg.rest.oauth2.scope | | Specifies the resource scope and permission level that users can access after authorization when using oauth2 authentication | - | No |
| iceberg.rest.oauth2.credential | | oauth2 credentials used to access server-uri to obtain token | - | No |
| iceberg.rest.oauth2.server-uri | | URI address for obtaining oauth2 token, used in conjunction with iceberg.rest.oauth2.credential | - | No |
| iceberg.rest.vended-credentials-enabled | | Whether to enable vended-credentials functionality. When enabled, it will obtain storage system access credentials such as access-key and secret-key from the rest server, eliminating the need for manual specification. Requires rest server support for this capability. | false | No |

| Property Name | Legacy Name | Description | Default Value | Required |
|---------------------------------------|-------------|--|---------------|----------|
| iceberg.rest.nested-namespace-enabled | | (Supported since version 3.1.2+) Whether to enable support for Nested Namespace. Default is false. If true, Nested Namespace will be flattened and displayed as Database names, such as parent_ns.child_ns. Some Rest Catalog services do not support Nested Namespace, such as AWS Glue, so this parameter should be set to false | No | |

Note:

1. OAuth2 authentication and vended-credentials functionality are supported starting from version 3.1.0.
2. For versions prior to 3.1.0, please use the legacy names.
3. For AWS Glue Rest Catalog, please refer to the [AWS Glue documentation](#)

Nested Namespace

Since 3.1.2, to fully access Nested Namespace, in addition to setting `iceberg.rest.nested-namespace-enabled` to `true` in the Catalog properties, you also need to enable the following global parameter:

```
SET GLOBAL enable_nested_namespace=true;
```

Assuming the Catalog is “ice”, Namespace is “ns1.ns2”, and Table is “tbl1”, you can access Nested Namespace in the following ways:

```
mysql> USE ice.ns1.ns2;
mysql> SELECT k1 FROM ice.`ns1.ns2`.tbl1;
mysql> SELECT tbl1.k1 FROM `ns1.ns2`.tbl1;
mysql> SELECT `ns1.ns2`.tbl1.k1 FROM ice.`ns1.ns2`.tbl1;
mysql> SELECT ice.`ns1.ns2`.tbl1.k1 FROM tbl1;
mysql> REFRESH CATALOG ice;
mysql> REFRESH DATABASE ice.`ns1.ns2`;
mysql> REFRESH TABLE ice.`ns1.ns2`.tbl1;
```

Example Configurations

- Rest Catalog service without authentication

```
CREATE CATALOG minio_iceberg PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'uri' = 'http://172.21.0.1:8181',
  's3.access_key' = '<ak>',
  's3.secret_key' = '<sk>',
  's3.endpoint' = 'http://10.0.0.1:9000',
  's3.region' = 'us-east-1'
);
```

- Connecting to AWS Glue Rest Catalog

```
CREATE CATALOG glue_iceberg PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'https://glue.<region>.amazonaws.com/iceberg',
  'warehouse' = '<account_id>:s3tables/catalog/<s3_table_bucket_name>',
  'iceberg.rest.sigv4-enabled' = 'true',
  'iceberg.rest.signing-name' = 'glue',
  'iceberg.rest.access-key-id' = '<ak>',
  'iceberg.rest.secret-access-key' = '<sk>',
  'iceberg.rest.signing-region' = '<region>'
);
```

- Connecting to Databricks Unity Iceberg Rest Catalog

```
CREATE CATALOG unity_iceberg properties(
  "uri" = "https://dbc-59918a85-6c3a.cloud.databricks.com/api/2.1/unity-catalog/iceberg-rest/",
  "type" = "iceberg",
  "warehouse" = "<catalog_name>",
  "iceberg.catalog.type" = "rest",
  "iceberg.rest.security.type" = "oauth2",
  "iceberg.rest.oauth2.token" = "<token>",
  "iceberg.rest.vended-credentials-enabled" = "true",
  's3.endpoint' = 'https://s3.us-east-2.amazonaws.com',
  's3.region' = 'us-east-2'
);
```

- Connecting to Apache Polaris Rest Catalog

```
-- Enable vended-credentials
CREATE CATALOG polaris_iceberg PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'http://YOUR_POLARIS_HOST:8181/api/catalog',
  'warehouse' = '<catalog_name>',
  'iceberg.rest.security.type' = 'oauth2',
  'iceberg.rest.oauth2.credential' = 'client_id:client_secret',
  'iceberg.rest.oauth2.server-uri' = 'http://YOUR_POLARIS_HOST:8181/api/catalog/v1/oauth/tokens',
  'iceberg.rest.oauth2.scope' = 'PRINCIPAL_ROLE:doris_pr_role',
  'iceberg.rest.vended-credentials-enabled' = 'true',
  's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',
  's3.region' = 'us-west-2'
);

-- Disable vended-credentials
CREATE CATALOG polaris_iceberg PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
```

```

'iceberg.rest.uri' = 'http://YOUR_POLARIS_HOST:8181/api/catalog',
'warehouse' = '<catalog_name>',
'iceberg.rest.security.type' = 'oauth2',
'iceberg.rest.oauth2.credential' = '6e155b128dc06c13:ce9fbb4cc91c43ff2955f2c6545239d7',
'iceberg.rest.oauth2.server-uri' = 'http://YOUR_POLARIS_HOST:8181/api/catalog/v1/oauth/tokens',
'iceberg.rest.oauth2.scope' = 'PRINCIPAL_ROLE:doris_pr_role',
's3.access_key' = '<ak>',
's3.secret_key' = '<sk>',
's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',
's3.region' = 'us-west-2'
);

```

- Connecting to Snowflake Open Catalog (Since 3.1.2)

```

-- Enable vended-credentials
CREATE CATALOG snowflake_open_catalog PROPERTIES (
  'type' = 'iceberg',
  'warehouse' = '<catalog_name>',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'https://<open_catalog_account>.snowflakecomputing.com/polaris/api/catalog',
  'iceberg.rest.security.type' = 'oauth2',
  'iceberg.rest.oauth2.credential' = '<client_id>:<client_secret>',
  'iceberg.rest.oauth2.scope' = 'PRINCIPAL_ROLE:<principal_role>',
  'iceberg.rest.vended-credentials-enabled' = 'true',
  's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',
  's3.region' = 'us-west-2',
  'iceberg.rest.nested-namespace-enabled' = 'true'
);

```

```

-- Disable vended-credentials
CREATE CATALOG snowflake_open_catalog PROPERTIES (
  'type' = 'iceberg',
  'warehouse' = '<catalog_name>',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'https://<open_catalog_account>.snowflakecomputing.com/polaris/api/catalog',
  'iceberg.rest.security.type' = 'oauth2',
  'iceberg.rest.oauth2.credential' = '<client_id>:<client_secret>',
  'iceberg.rest.oauth2.scope' = 'PRINCIPAL_ROLE:<principal_role>',
  's3.access_key' = '<ak>',
  's3.secret_key' = '<sk>',
  's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',
  's3.region' = 'us-west-2',
  'iceberg.rest.nested-namespace-enabled' = 'true'
);

```

- Connecting to Apache Gravitino Rest Catalog

```

-- Enable vended-credentials
CREATE CATALOG gravitino_iceberg PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'http://127.0.0.1:9001/iceberg/',
  'warehouse' = 's3://gravitino-iceberg-demo/warehouse',
  'iceberg.rest.vended-credentials-enabled' = 'true',
  's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',
  's3.region' = 'us-west-2'
);

-- Disable vended-credentials
CREATE CATALOG gravitino_iceberg PROPERTIES (

```

```
'type' = 'iceberg',  
'iceberg.catalog.type' = 'rest',  
'iceberg.rest.uri' = 'http://127.0.0.1:9001/iceberg/',  
'warehouse' = 's3://gravitino-iceberg-demo/warehouse',  
'iceberg.rest.vended-credentials-enabled' = 'false',  
's3.access_key' = '<ak>',  
's3.secret_key' = '<sk>',  
's3.endpoint' = 'https://s3.us-west-2.amazonaws.com',  
's3.region' = 'us-west-2'  
);
```

File System

Iceberg Catalog and Paimon Catalog support accessing metadata directly from the file system.

For related connection information, please refer to the documentation of each respective Catalog and the parameters related to the corresponding

HDFS | Storages

HDFS

This document describes the parameters required for accessing HDFS. These parameters apply to:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties
- Backup and restore

Parameter Overview

| Property Name | Legacy Name | Description | Default Value | Required |
|--|------------------------------------|--|---------------|----------|
| hdfs.authentication.type | hadoop.security.authenti
cation | Specifies the authentication type. Optional values are kerberos or simple. If kerberos is selected, the system will use Kerberos authentication to interact with HDFS; if simple is used, it means no authentication is used, suitable for open HDFS clusters. Selecting kerberos requires configuring the corresponding principal and keytab. | simple | No |
| hdfs.authentication.kerberos.principal | hadoop.kerberos.princip
al | When the authentication type is kerberos, specify the Kerberos principal. A Kerberos principal is a unique identity string that typically includes service name, hostname, and domain name. | - | No |

| Property Name | Legacy Name | Description | Default Value | Required |
|-------------------------------------|------------------------|---|-------------------|----------|
| hdfs.authentication.kerberos.keytab | hadoop.kerberos.keytab | This parameter specifies the keytab file path for Kerberos authentication. The keytab file stores encrypted credentials, allowing the system to authenticate automatically without requiring users to manually enter passwords. | - | No |
| hdfs.impersonation.enabled | - | If true, enables HDFS impersonation functionality. Uses the proxy user configured in core-site.xml to proxy Doris login users for HDFS operations | Not supported yet | - |
| hadoop.username | - | When the authentication type is simple, this user will be used to access HDFS. By default, the Linux system user running the Doris process will be used for access | - | - |
| hadoop.config.resources | - | Specifies the HDFS configuration file directory (must include hdfs-site.xml and core-site.xml), using relative paths. The default directory is /plugins/hadoop/conf/ under the (FE/BE) deployment directory (can be changed by modifying hadoop_config_dir in fe.conf/be.conf to change the default path). All FE and BE nodes need to configure the same relative path.
Example:
hadoop/conf/core-site.xml,hadoop/conf/hdfs-site.xml | - | - |

| Property Name | Legacy Name | Description | Default Value | Required |
|------------------|-------------|---|---------------|----------|
| dfs.nameservices | - | Manually configure HDFS high availability cluster parameters. If using <code>hadoop.config.resources</code> configuration, parameters will be automatically read from <code>hdfs-site.xml</code> . Need to be used with the following parameters:
<code>dfs.ha.namenodes.your-nameservice</code> ,
<code>dfs.namenode.rpc-address.your-nameservice.nn1</code> ,
<code>dfs.client.failover.proxy.provider</code> , etc. | - | - |

For versions before 3.1, please use the legacy names.

Authentication Configuration

HDFS supports two authentication methods:

- Simple
- Kerberos

Simple Authentication

Simple authentication is suitable for HDFS clusters that have not enabled Kerberos.

Using Simple authentication, you can set the following parameters or use the default values directly:

```
"hdfs.authentication.type" = "simple"
```

In Simple authentication mode, you can use the `hadoop.username` parameter to specify the username. If not specified, it defaults to the username of the current process.

Examples:

Using `lakers` username to access HDFS

```
"hdfs.authentication.type" = "simple",
"hadoop.username" = "lakers"
```

Using default system user to access HDFS

```
"hdfs.authentication.type" = "simple"
```

Kerberos Authentication

Kerberos authentication is suitable for HDFS clusters with Kerberos enabled.

Using Kerberos authentication, you need to set the following parameters:

```
"hdfs.authentication.type" = "kerberos",  
"hdfs.authentication.kerberos.principal" = "<your_principal>",  
"hdfs.authentication.kerberos.keytab" = "<your_keytab>"
```

In Kerberos authentication mode, you need to set the Kerberos principal and keytab file path.

Doris will access HDFS with the identity specified by the `hdfs.authentication.kerberos.principal` property, using the keytab specified by `keytab` to authenticate the Principal.

Note:

The keytab file must exist on every FE and BE node with the same path, and the user running the Doris process must have read permissions for the keytab file.

Example:

```
"hdfs.authentication.type" = "kerberos",  
"hdfs.authentication.kerberos.principal" = "hdfs/hadoop@HADOOP.COM",  
"hdfs.authentication.kerberos.keytab" = "/etc/security/keytabs/hdfs.keytab",
```

HDFS HA Configuration

If HDFS HA mode is enabled, need to configure `dfs.nameservices` related parameters:

```
'dfs.nameservices' = '<your-nameservice>',  
'dfs.ha.namenodes.<your-nameservice>' = '<nn1>,<nn2>',  
'dfs.namenode.rpc-address.<your-nameservice>.<nn1>' = '<nn1_host:port>',  
'dfs.namenode.rpc-address.<your-nameservice>.<nn2>' = '<nn2_host:port>',  
'dfs.client.failover.proxy.provider.<your-nameservice>' =  
'org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider',
```

Example:

```
'dfs.nameservices' = 'nameservice1',  
'dfs.ha.namenodes.nameservice1' = 'nn1,nn2',  
'dfs.namenode.rpc-address.nameservice1.nn1' = '172.21.0.2:8088',  
'dfs.namenode.rpc-address.nameservice1.nn2' = '172.21.0.3:8088',  
'dfs.client.failover.proxy.provider.nameservice1' =  
'org.apache.hadoop.hdfs.server.namenode.ha.ConfiguredFailoverProxyProvider',
```

Configuration Files

This feature is supported since version 3.1.0

Doris supports specifying the HDFS configuration file directory through the `hadoop.config.resources` parameter.

The configuration file directory must contain `hdfs-site.xml` and `core-site.xml` files. The default directory is `/plugins/hadoop_conf/` under the (FE/BE) deployment directory. All FE and BE nodes need to configure the same relative path.

If the configuration files contain the above parameters mentioned in this document, user-explicitly configured parameters take priority. Configuration files can specify multiple files, separated by commas, such as `hadoop/conf/core-site.xml,hadoop/conf/hdfs-site.xml`.

Examples:

```
-- Multiple configuration files
'hadoop.config.resources'='hdfs-cluster-1/core-site.xml,hdfs-cluster-1/hdfs-site.xml'
-- Single configuration file
'hadoop.config.resources'='hdfs-cluster-2/hdfs-site.xml'
```

HDFS IO Optimization

In some cases, high HDFS load may cause reading data replicas on HDFS to take a long time, thereby slowing down overall query efficiency. The following introduces some related optimization configurations.

Hedged Read

HDFS Client provides Hedged Read functionality. This feature can start another read thread to read the same data when a read request exceeds a certain threshold without returning, using whichever returns first.

Note: This feature may increase the load on the HDFS cluster, please use it judiciously.

You can enable this feature in the following way:

```
"dfs.client.hedged.read.threadpool.size" = "128",
"dfs.client.hedged.read.threshold.millis" = "500"
```

- `dfs.client.hedged.read.threadpool.size`

Represents the number of threads used for Hedged Read, which are shared by one HDFS Client. Usually, for one HDFS cluster, BE nodes share one HDFS Client.

- `dfs.client.hedged.read.threshold.millis`

Read threshold in milliseconds. When a read request exceeds this threshold without returning, it will trigger Hedged Read.

After enabling, you can see related parameters in Query Profile:

- TotalHedgedRead

Number of times Hedged Read was initiated.

- HedgedReadWins

Number of successful Hedged Read attempts (initiated and returned faster than the original request).

Note that the values here are cumulative values for a single HDFS Client, not values for a single query. The same HDFS Client is reused by multiple queries.

dfs.client.socket-timeout

`dfs.client.socket-timeout` is a client configuration parameter in Hadoop HDFS used to set the socket timeout when the client establishes connections or reads data with DataNode or NameNode, in milliseconds. The default value of this parameter is usually 60,000 milliseconds.

Reducing this parameter value allows the client to timeout faster and retry or switch to other nodes when encountering network delays, slow DataNode responses, or connection exceptions. This helps reduce wait times and improve system response speed. For example, in some tests, setting `dfs.client.socket-timeout` to a smaller value (such as 5000 milliseconds) can quickly detect DataNode delays or failures, avoiding long waits.

Note:

- Setting the timeout too small may cause frequent timeout errors during network fluctuations or high node load, affecting task stability.
- It is recommended to reasonably adjust this parameter value based on actual network environment and system load conditions to balance response speed and system stability.
- This parameter should be set in the client configuration file (such as `hdfs-site.xml`) to ensure the client uses the correct timeout when communicating with HDFS.

In summary, properly configuring the `dfs.client.socket-timeout` parameter can improve I/O response speed while ensuring system stability and reliability.

HDFS Access Port Requirements (NameNode & DataNode only)

Doris requires the following ports to be open to access HDFS:

| Service | Port Purpose | Default Port | Protocol |
|----------|------------------------------|--------------|----------|
| NameNode | RPC (client/metadata access) | 8020 | TCP |
| DataNode | Data transfer (block I/O) | 9866 | TCP |

Notes: - Ports may be customized in `core-site.xml` & `hdfs-site.xml`. Use actual configs. - When Kerberos authentication is enabled, Doris must also be able to reach the Kerberos KDC service. The KDC listens on TCP port 88 by default, but the actual port should follow your KDC configuration.

Debugging HDFS

Hadoop environment configuration is complex, and in some cases, connectivity issues and poor access performance may occur. Here are some third-party tools to help users quickly troubleshoot connectivity issues and basic performance problems.

HDFS Client

- Java: <https://github.com/morningman/hdfs-client-java>
- CPP: <https://github.com/morningman/hdfs-client-cpp>

These two tools can be used to quickly verify HDFS connectivity and read performance. Most of their Hadoop dependencies are the same as Doris's own Hadoop dependencies, so they can simulate Doris's HDFS access scenarios to the greatest extent.

The Java version uses Java to access HDFS and can simulate the logic of Doris FE side accessing HDFS.

The CPP version accesses HDFS through C++ calling libhdfs and can simulate the logic of Doris BE side accessing HDFS.

For specific usage, please refer to the README in each code repository.

S3 | Storages

S3

This document describes the parameters required for accessing AWS S3. These parameters apply to:

- Catalog properties.
- Table Valued Function properties.
- Broker Load properties.
- Export properties.
- Outfile properties.

Configure BE CA Certificate for HTTPS

Starting from Doris 2.1, you can explicitly configure `ca_cert_file_paths` in `be.conf` when Doris BE accesses S3 over HTTPS.

By default, if `ca_cert_file_paths` is not configured, Doris uses the operating system's default CA certificates. In most environments, you do not need to set this parameter manually. Configure it in the following cases:

- The BE node is missing system CA certificates, or the installed CA bundle is too old.
- The BE node runs in a minimal container or image that does not include the `ca-certificates` package.
- The default CA file path on the BE node is invalid, or the Doris process does not have read permission on the CA file.
- Your environment uses a self-signed certificate, a private CA, or a corporate proxy or gateway that re-signs TLS traffic.
- You encounter errors such as `Problem with the SSL CA cert` or `curl 77: Problem with the SSL CA cert (path? access rights?)` when accessing S3.

Example:

```
# be.conf
ca_cert_file_paths = /etc/ssl/certs/ca-certificates.crt
```

Common CA bundle paths:

- Debian / Ubuntu: `/etc/ssl/certs/ca-certificates.crt`
- CentOS / RockyLinux: `/etc/pki/ca-trust/extracted/openssl/ca-bundle.trust.crt`

Configure this item on every BE node that may access S3, and ensure that the certificate file exists and is readable by the Doris process. After updating `be.conf`, restart the affected BE nodes to apply the change.

Parameter Overview

| Property Name | Legacy Name | Description | Default | Required |
|-------------------------------|-------------|--|---------|----------|
| s3.endpoint | | S3 service access endpoint, e.g., s3.us-east-1.amazonaws.com | None | No |
| s3.access_key | | AWS Access Key for authentication | None | No |
| s3.secret_key | | AWS Secret Key for authentication | None | No |
| s3.region | | S3 region, e.g., us-east-1. Strongly recommended | None | Yes |
| s3.use_path_style | | Whether to use path-style access | FALSE | No |
| s3.connection.maximum | | Maximum number of connections for high concurrency scenarios | 50 | No |
| s3.connection.request.timeout | | Request timeout (milliseconds), controls connection acquisition timeout | 3000 | No |
| s3.connection.timeout | | Connection establishment timeout (milliseconds) | 1000 | No |
| s3.role_arn | | Role ARN specified when using Assume Role mode | None | No |
| s3.external_id | | External ID used with s3.role_arn | None | No |
| s3.credentials_provider_type | | Credentials provider type for AWS authentication (used without AK/SK; used as STS source credentials in IAM Role mode) | DEFAULT | No |

Version note: s3.credentials_provider_type is supported since **3.1.4** and **4.0.3**.

Authentication Configuration

Doris supports the following three methods to access S3:

1. Direct Access Key and Secret Key (AK/SK)

```
"s3.access_key"="your-access-key",  
"s3.secret_key"="your-secret-key",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

2. IAM Role (Assume Role) mode

Suitable for cross-account and temporary authorization access. Doris automatically obtains temporary credentials through role authorization.

```
"s3.role_arn"="arn:aws:iam::123456789012:role/demo-role",  
"s3.external_id"="external-identifier",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

Configure s3.credentials_provider_type in IAM Role mode

When s3.role_arn is configured, s3.credentials_provider_type controls which source credentials provider is used for STS AssumeRole:

1. Get source credentials from s3.credentials_provider_type.
2. Call STS AssumeRole with source credentials.
3. Access S3 with the returned temporary credentials.

IAM Role + s3.credentials_provider_type examples

Example 1: EC2 Instance Profile as STS source credentials

```
"s3.role_arn"="arn:aws:iam::123456789012:role/demo-role",  
"s3.external_id"="external-identifier",  
"s3.credentials_provider_type"="INSTANCE_PROFILE",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

Example 2: Web Identity (for example IRSA) as STS source credentials

```
"s3.role_arn"="arn:aws:iam::123456789012:role/demo-role",  
"s3.credentials_provider_type"="WEB_IDENTITY",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

Example 3: Container metadata as STS source credentials

```
"s3.role_arn"="arn:aws:iam::123456789012:role/demo-role",  
"s3.credentials_provider_type"="CONTAINER",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

Example 4: Default provider chain as STS source credentials

```
"s3.role_arn"="arn:aws:iam::123456789012:role/demo-role",  
"s3.credentials_provider_type"="DEFAULT",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

3. Specify credential source with `s3.credentials_provider_type`

This is suitable for scenarios without explicit AK/SK, such as EC2 Instance Profile, container metadata, or Web Identity.

```
"s3.credentials_provider_type"="INSTANCE_PROFILE",  
"s3.endpoint"="https://s3.us-east-1.amazonaws.com",  
"s3.region"="us-east-1"
```

Supported values for `s3.credentials_provider_type`

| Value | Description |
|-------------------|---|
| DEFAULT | Use default provider chain |
| ENV | Read credentials from environment variables |
| SYSTEM_PROPERTIES | Read credentials from system properties |
| WEB_IDENTITY | Use Web Identity Token credentials |
| CONTAINER | Use container metadata credentials |
| INSTANCE_PROFILE | Use EC2 Instance Profile credentials |
| ANONYMOUS | Anonymous access (for public buckets) |

Effective rules when configured together

1. If `s3.access_key` and `s3.secret_key` are both configured, AK/SK is used first.
2. If AK/SK is not configured and `s3.role_arn` is configured, IAM Role is used. In this case, `s3.credentials_provider_type` is used to select STS source credentials.
3. If neither AK/SK nor `s3.role_arn` is configured, `s3.credentials_provider_type` directly determines the credentials provider used by the S3 client.

Note: `s3.access_key` and `s3.secret_key` must be configured together.

Accessing S3 Directory Bucket

This feature is supported since version 3.1.0.

Amazon S3 Express One Zone (also known as Directory Bucket) provides higher performance, but has a different endpoint format.

- Regular bucket: `s3.us-east-1.amazonaws.com`
- Directory Bucket: `s3express-usw2-az1.us-west-2.amazonaws.com`

For more available regions, refer to: [AWS Official Documentation](#)

Example:

```
"s3.access_key"="ak",
"s3.secret_key"="sk",
"s3.endpoint"="https://s3express-usw2-az1.us-west-2.amazonaws.com",
"s3.region"="us-west-2"
```

Permission Policies

Depending on the use case, permissions can be categorized into **read-only** and **read-write** policies.

1. Read-only Permissions

Only allows reading objects from S3. Suitable for LOAD, TVF, querying EXTERNAL CATALOG, and other scenarios.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:GetObjectVersion",
      ],
      "Resource": "arn:aws:s3:::<your-bucket>/your-prefix/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::<your-bucket>"
    }
  ]
}
```

2. Read-write Permissions

Based on read-only permissions, additionally allows deleting, creating, and modifying objects. Suitable for EXPORT, OUTFILE, and EXTERNAL CATALOG write-back scenarios.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:GetObjectVersion",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion",
        "s3:AbortMultipartUpload",
        "s3:ListMultipartUploadParts"
      ]
    }
  ]
}
```

```
    ],
    "Resource": "arn:aws:s3:::<your-bucket>/<your-prefix>/*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "s3:ListBucket",
      "s3:GetBucketLocation",
      "s3:GetBucketVersioning",
      "s3:GetLifecycleConfiguration"
    ],
    "Resource": "arn:aws:s3:::<your-bucket>"
  }
]
```

Notes

1. Placeholder Replacement

- <bucket> → Your S3 Bucket name.
- <account-id> → Your AWS account ID (12-digit number).

2. Principle of Least Privilege

- If only querying, do not grant write permissions.

Azure Blob

Starting from version 3.1.3, Doris supports accessing Azure Blob storage.

This document describes the parameters required to access Microsoft Azure Blob storage, which apply to the following scenarios:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties
- Backup / Restore properties

Azure Blob Storage currently does not support ARM architectures.

Configure BE CA Certificate for HTTPS

Starting from Doris 3.1.5 and 4.0.5, you can explicitly configure `ca_cert_file_paths` in `be.conf` when Doris BE accesses Azure Blob Storage over HTTPS.

By default, if `ca_cert_file_paths` is not configured, Doris uses the operating system's default CA certificates. In most environments, you do not need to set this parameter manually. Configure it in the following cases:

- The BE node is missing system CA certificates, or the installed CA bundle is too old.
- The BE node runs in a minimal container or image that does not include the `ca-certificates` package.
- The default CA file path on the BE node is invalid, or the Doris process does not have read permission on the CA file.
- Your environment uses a self-signed certificate, a private CA, or a corporate proxy or gateway that re-signs TLS traffic.
- You encounter errors such as `Problem with the SSL CA cert` or `curl 77: Problem with the SSL CA cert (path? access rights?)` when accessing Azure Blob Storage.

Example:

```
# be.conf
ca_cert_file_paths = /etc/ssl/certs/ca-certificates.crt
```

Common CA bundle paths:

- Debian / Ubuntu: `/etc/ssl/certs/ca-certificates.crt`
- CentOS / RockyLinux: `/etc/pki/ca-trust/extracted/openssl/ca-bundle.trust.crt`

Configure this item on every BE node that may access Azure Blob Storage, and ensure that the certificate file exists and is readable by the Doris process. After updating `be.conf`, restart the affected BE nodes to apply the change.

Parameter Overview

| Property Name | Former Name | Description | Default Value | Required |
|--------------------|-------------|--|---------------|----------|
| azure.account_name | | Azure storage account name (Account Name), which is the storage account name created in the Azure portal. | | Yes |
| azure.account_key | | Account Key for Azure Blob storage | | Yes |
| azure.endpoint | | Access endpoint for Azure Blob storage, typically formatted as <code>https://.blob.core.windows.net</code> | | Yes |
| fs.azure.support | | Whether to enable Azure Blob storage | true | Yes |

- Enable Azure Blob Storage

You must explicitly configure `"provider" = "AZURE"` or `"fs.azure.support" = "true"` to indicate that Azure Blob storage is enabled.

- Get `azure.account_name`

1. Log in to [Azure Portal](#)
2. Open **Storage Accounts** and select the target account
3. You can see the **Storage Account Name** on the **Overview** page

```
"azure.account_name" = "myblobstorage"
```

- Get `azure.account_key`

1. Log in to [Azure Portal](#)
2. Open **Storage Accounts** and select the target account
3. Select **Access keys** in the left navigation bar
4. Click "Show key" in **key1** or **key2**, and copy the **Key value**

```
"azure.account_key" = "EXAMPLE_I_A...=="
```

Google Cloud Storage | Storages

Google Cloud Storage

The document is under development.

Aliyun OSS

This document describes the parameters required to access Alibaba Cloud OSS, which are applicable to the following scenarios:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties

OSS

Doris uses S3 Client to access Alibaba Cloud OSS through S3-compatible protocol.

Parameter Overview

| Property Name | Legacy Name | Description | Default Value |
|--------------------------------|-------------------------------|---|---------------|
| oss.endpoint | s3.endpoint | OSS endpoint, specifies the access endpoint for Alibaba Cloud OSS. Note that OSS and OSS HDFS have different endpoints. | None |
| oss.access_key | s3.access_key | OSS Access Key for authentication | None |
| oss.secret_key | s3.secret_key | OSS Secret Key, used together with Access Key | None |
| oss.region | s3.region | OSS region, specifies the region of Alibaba Cloud OSS | None |
| oss.use_path_style | s3.use_path_style | Whether to use path-style access. Recommended to set to true for compatibility with MinIO and other non-AWS S3 services | FALSE |
| oss.connection.maximum | s3.connection.maximum | Maximum number of connections, specifies the maximum number of connections established with OSS service | 50 |
| oss.connection.request.timeout | s3.connection.request.timeout | Request timeout (milliseconds), specifies the request timeout when connecting to OSS service | 3000 |
| oss.connection.timeout | s3.connection.timeout | Connection timeout (milliseconds), specifies the timeout when establishing connection with OSS service | 1000 |

Before version 3.1, use legacy name

Example Configuration

```
"oss.access_key" = "your-access-key",  
"oss.secret_key" = "your-secret-key",
```

```
"oss.endpoint" = "oss-cn-beijing.aliyuncs.com",  
"oss.region" = "cn-beijing"
```

For versions before 3.1:

```
"s3.access_key" = "your-access-key",  
"s3.secret_key" = "your-secret-key",  
"s3.endpoint" = "oss-cn-beijing.aliyuncs.com",  
"s3.region" = "cn-beijing"
```

Usage Recommendations

- It is recommended to use the `oss.` prefix for configuration parameters to ensure consistency and clarity with Alibaba Cloud OSS.
- For versions before 3.1, please use the legacy name `s3.` as the prefix.
- Configuring `oss.region` can improve access accuracy and performance, recommended to set.
- Connection pool parameters can be adjusted according to concurrency requirements to avoid connection blocking.

OSS-HDFS

OSS-HDFS service (JindoFS service) is an Alibaba Cloud native data lake storage functionality. Based on unified metadata management capabilities, it is compatible with HDFS file system interfaces and meets data lake computing scenarios in big data and AI fields.

Accessing data stored on OSS-HDFS is slightly different from directly accessing OSS services. Please refer to this documentation for details.

Parameter Overview

| Property Name | Legacy Name | Description | Default Value | Required |
|----------------------------------|----------------|---|---------------|----------|
| oss.hdfs.endpoint | oss.endpoint | Alibaba Cloud OSS-HDFS service endpoint, e.g., cn-hangzhou.oss-dls.aliyuncs.com. | None | Yes |
| oss.hdfs.access_key | oss.access_key | OSS Access Key for authentication | None | Yes |
| oss.hdfs.secret_key | oss.secret_key | OSS Secret Key, used together with Access Key | None | Yes |
| oss.hdfs.region | oss.region | Region ID where the OSS bucket is located, e.g., cn-beijing. | None | Yes |
| oss.hdfs.fs.defaultFS | | Supported in version 3.1. Specifies the file system access path for OSS, e.g., <code>oss://my-bucket/</code> . | None | No |
| oss.hdfs.hadoop.config.resources | | Supported in version 3.1. Specifies the path containing OSS file system configuration. Requires relative path. Default directory is <code>/plugins/hadoop_conf/</code> under the (FE/BE) deployment directory (can be changed by modifying <code>hadoop_config_dir</code> in <code>fe.conf/be.conf</code>). All FE and BE nodes need to configure the same relative path. Example: <code>hadoop/conf/core-site.xml, hadoop/conf/hdfs-site.xml</code> . | None | No |

| Property Name | Legacy Name | Description | Default Value | Required |
|---------------------|------------------|---|---------------|----------|
| fs.oss-hdfs.support | oss.hdfs.enabled | Supported in version 3.1. Explicitly declares the enabling of OSS-HDFS functionality. Needs to be set to true | None | No |

For versions before 3.1, please use legacy names.

Endpoint Configuration

`oss.hdfs.endpoint`: Used to specify the OSS-HDFS service endpoint.

Endpoint is the entry address for accessing Alibaba Cloud OSS, formatted as `<region>.oss-dls.aliyuncs.com`, e.g., `cn-hangzhou.oss-dls.aliyuncs.com`.

We perform strict format validation to ensure the endpoint conforms to the Alibaba Cloud OSS endpoint format.

For backward compatibility, the endpoint configuration allows the inclusion of `https://` or `http://` prefixes. The system will automatically parse and ignore the protocol part during format validation.

When using legacy names, the system determines whether it's an OSS-HDFS service based on whether the endpoint contains `oss-dls`.

Configuration Files

Supported in version 3.1

OSS-HDFS supports specifying HDFS-related configuration file directories through the `oss.hdfs.hadoop.config.resources` parameter.

The configuration file directory must contain `hdfs-site.xml` and `core-site.xml` files. The default directory is `/plugins/hadoop_conf/` under the (FE/BE) deployment directory. All FE and BE nodes need to configure the same relative path.

If the configuration files contain the parameters mentioned above in this document, the explicitly configured parameters by the user take precedence. Configuration files can specify multiple files, separated by commas, such as `hadoop/conf/core-site.xml,hadoop/conf/hdfs-site.xml`.

Example Configuration

```
"fs.oss-hdfs.support" = "true",
"oss.hdfs.access_key" = "your-access-key",
"oss.hdfs.secret_key" = "your-secret-key",
"oss.hdfs.endpoint" = "cn-hangzhou.oss-dls.aliyuncs.com",
"oss.hdfs.region" = "cn-hangzhou"
```

For versions before 3.1:

```
"oss.hdfs.enabled" = "true",  
"oss.access_key" = "your-access-key",  
"oss.secret_key" = "your-secret-key",  
"oss.endpoint" = "cn-hangzhou.oss-dls.aliyuncs.com",  
"oss.region" = "cn-hangzhou"
```

Tencent COS

This document describes the parameters required to access Tencent Cloud COS, which apply to the following scenarios:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties

Doris uses S3 Client to access Tencent Cloud COS through S3-compatible protocol.

Parameter Overview

| Property Name | Legacy Name | Description | Default Value | Required |
|--------------------------------|-------------------------------|--|---------------|----------|
| cos.endpoint | s3.endpoint | COS endpoint, specifies the access endpoint for Tencent Cloud COS | | Yes |
| cos.access_key | s3.access_key | COS access key, used for authentication to access COS | | Yes |
| cos.secret_key | s3.secret_key | COS secret key, used together with access key for authentication | | Yes |
| cos.region | s3.region | COS region, specifies the region of Tencent Cloud COS | | No |
| cos.connection.maximum | s3.connection.maximum | S3 maximum connections, specifies the maximum number of connections to COS service | 50 | No |
| cos.connection.request.timeout | s3.connection.request.timeout | S3 request timeout in milliseconds, specifies the request timeout when connecting to COS service | 3000 | No |
| cos.connection.timeout | s3.connection.timeout | S3 connection timeout in milliseconds, specifies the timeout when establishing connection to COS service | 1000 | No |

Before version 3.1, use legacy name

Configuration Examples

```
"cos.access_key" = "your-access-key",  
"cos.secret_key" = "your-secret-key",  
"cos.endpoint" = "cos.ap-beijing.myqcloud.com",  
"cos.region" = "ap-beijing"
```

For versions before 3.1:

```
"s3.access_key" = "ak",  
"s3.secret_key" = "sk",  
"s3.endpoint" = "cos.ap-beijing.myqcloud.com",  
"s3.region" = "ap-beijing"
```

Usage Recommendations

- It is recommended to use the `cos.` prefix for configuration parameters to ensure consistency and clarity with Tencent Cloud COS.
- For versions before 3.1, please use the legacy `s3.` prefix.
- Configuring `cos.region` can improve access accuracy and performance, and it is recommended to set it.
- Connection pool parameters can be adjusted according to concurrency requirements to avoid connection blocking.

Huawei OBS

This document describes the parameters required to access Huawei Cloud OBS, which are applicable to the following scenarios:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties

Doris uses S3 Client to access Huawei Cloud OBS through S3-compatible protocol.

Parameter Overview

| Property Name | Former Name | Description | Default Value | Required |
|--------------------------------|-------------------------------|---|---------------|----------|
| obs.endpoint | s3.endpoint | OBS endpoint, specifies the access endpoint for Huawei Cloud OBS | | Yes |
| obs.access_key | s3.access_key | OBS access key, used for authentication | | Yes |
| obs.secret_key | s3.secret_key | OBS secret key, used together with access key for authentication | | Yes |
| obs.region | s3.region | OBS region, specifies the region of Huawei Cloud OBS | | No |
| obs.use_path_style | s3.use_path_style | Whether to use path-style access. Recommended to set to true for compatibility with non-AWS S3 services like MinIO/Ceph | FALSE | No |
| obs.connection.maximum | s3.connection.maximum | Maximum number of connections to OBS service | 50 | No |
| obs.connection.request.timeout | s3.connection.request.timeout | Request timeout in milliseconds for connecting to OBS service | 3000 | No |
| obs.connection.timeout | s3.connection.timeout | Connection timeout in milliseconds for establishing connection to OBS service | 1000 | No |

Before version 3.1, use legacy name

Example Configuration

```
"obs.access_key" = "your-access-key",
"obs.secret_key" = "your-secret-key",
"obs.endpoint" = "obs.cn-north-4.myhuaweicloud.com",
"obs.region" = "cn-north-4"
```

For versions before 3.1:

```
"s3.access_key" = "your-access-key",  
"s3.secret_key" = "your-secret-key",  
"s3.endpoint" = "obs.cn-north-4.myhuaweicloud.com",  
"s3.region" = "cn-north-4",
```

Usage Recommendations

- It is recommended to use the `obs.` prefix for configuration parameters to ensure consistency and clarity with Huawei Cloud OBS.
- For versions before 3.1, please use the former name with `s3.` prefix.
- Configuring `obs.region` can improve access accuracy and performance, it is recommended to set it.
- Connection pool parameters can be adjusted according to concurrency requirements to avoid connection blocking.

Baidu BOS

Document is under development.

MinIO | Storages

MinIO

This document describes the parameters required to access MinIO, which apply to the following scenarios:

- Catalog properties
- Table Valued Function properties
- Broker Load properties
- Export properties
- Outfile properties

Doris uses S3 Client to access MinIO through S3-compatible protocol.

Parameter Overview

| Property Name | Legacy Name | Description | Default Value | Required |
|----------------------------------|-------------------------------|---|---------------|----------|
| minio.endpoint | s3.endpoint | MinIO endpoint, the access endpoint for MinIO | | Yes |
| minio.access_key | s3.access_key | MinIO access key, the MinIO access key used for authentication | | Yes |
| minio.secret_key | s3.secret_key | MinIO secret key, the secret key used together with access key | | Yes |
| minio.connection.maximum | s3.connection.maximum | S3 maximum connections, specifies the maximum number of connections established with MinIO service | 50 | No |
| minio.connection.request.timeout | s3.connection.request.timeout | S3 request timeout, in milliseconds, specifies the request timeout when connecting to MinIO service | 3000 | No |
| minio.connection.timeout | s3.connection.timeout | S3 connection timeout, in milliseconds, specifies the timeout when establishing connection with MinIO service | 1000 | No |
| minio.use_path_style | s3.use_path_style | Whether to use path-style access. Recommended to set to true for compatibility with MinIO and other non-AWS S3 services | FALSE | No |

Using Path-style Access

MinIO uses Host-style access by default, but also supports Path-style access. You can switch by setting the `minio.use_path_style` parameter.

- Host-style access (default): `https://bucket.minio.example.com`
- Path-style access (when enabled): `https://minio.example.com/bucket`

Example Configuration

```
"minio.access_key" = "your-access-key",  
"minio.secret_key" = "your-secret-key",  
"minio.endpoint" = "http://minio.example.com:9000"
```

For versions before 3.1:

```
"s3.access_key" = "your-access-key",  
"s3.secret_key" = "your-secret-key",  
"s3.endpoint" = "http://minio.example.com:9000"
```

Usage Recommendations

- It is recommended to use the `minio.` prefix for configuration parameters to ensure consistency and clarity with MinIO.
- For versions before 3.1, please use the legacy name `s3.` as the prefix.
- Connection pool parameters can be adjusted according to concurrency requirements to avoid connection

Parquet | File Formats

Parquet

This document introduces the support for reading and writing Parquet file formats in Doris. It applies to the following features:

- Reading and writing data in the Catalog.
- Reading data using Table Valued Functions.
- Reading data with Broker Load.
- Writing data during Export.
- Writing data with Outfile.

Supported Compression Formats

- uncompressed
- snappy
- lz4
- zstd
- gzip
- lzo
- brotli

Parameters

Session Variables

- `enable_parquet_lazy_mat` (2.1+, 3.0+)

Controls whether the Parquet Reader enables lazy materialization. Default is true.

- `hive_parquet_use_column_names` (2.1.6+, 3.0.3+)

When reading Parquet data types from Hive tables, Doris will, by default, read data from columns in the Parquet file that have the same name as the columns in the Hive table. When this variable is set to `false`, Doris will read data from the Parquet file based on the column order in the Hive table, regardless of column names. This is similar to the `parquet.column.index.access` variable in Hive. This parameter only applies to top-level column names and is ineffective for columns inside Structs.

BE Configuration

- `enable_parquet_page_index` (2.1.5+, 3.0+)

Determines whether the Parquet Reader uses the Page Index to filter data. This is only for debugging purposes, in case the page index sometimes filters incorrect data. Default value is `false`.

- `parquet_header_max_size_mb` (2.1+, 3.0+)

The maximum buffer size allocated when reading the Parquet Page header. Default is 1M.

- `parquet_rowgroup_max_buffer_mb` (2.1+, 3.0+)

The maximum buffer size allocated when reading a Parquet Row Group. Default is 128M.

- `parquet_column_max_buffer_mb` (2.1+, 3.0+)

The maximum buffer size allocated when reading a Column within a Parquet Row Group. Default is 8M.

ORC | File Formats

ORC

This document introduces the support for reading and writing ORC file formats in Doris. It applies to the following functionalities:

- Reading and writing data in the Catalog.
- Reading data using Table Valued Functions.
- Reading data with Broker Load.
- Writing data during Export.
- Writing data with Outfile.

Supported Compression Formats

- uncompressed
- snappy
- lz4
- zstd
- lzo
- zlib

Parameters

Session Variables

- `enable_orc_lazy_mat` (2.1+, 3.0+)

Controls whether the ORC Reader enables lazy materialization. Default is true.

- `hive_orc_use_column_names` (2.1.6+, 3.0.3+)

When reading ORC data types from Hive tables, Doris will, by default, read data from columns in the ORC file that have the same name as the columns in the Hive table. When this variable is set to `false`, Doris will read data from the ORC file based on the column order in the Hive table, regardless of column names. This is similar to the `orc.force.positional.evolution` variable in Hive. This parameter only applies to top-level column names and is ineffective for columns inside Structs.

- `orc_tiny_stripe_threshold_bytes` (2.1.8+, 3.0.3+)

In ORC files, if the byte size of a Stripe is less than `orc_tiny_stripe_threshold`, it is considered a Tiny Stripe. For multiple consecutive Tiny Stripes, read optimization will be performed, i.e., multiple Tiny Stripes will be read at once to reduce the number of IO operations. If you do not want to use this optimization, you can set this value to 0. Default is 8M.

- `orc_once_max_read_bytes` (2.1.8+, 3.0.3+)

When using Tiny Stripe read optimization, multiple Tiny Stripes will be merged into a single IO operation. This parameter controls the maximum number of bytes for each IO request. You should not set this value smaller than `orc_tiny_stripe_threshold`. Default is 8M.

- `orc_max_merge_distance_bytes` (2.1.8+, 3.0.3+)

When using Tiny Stripe read optimization, since two Tiny Stripes to be read may not be consecutive, if the distance between two Tiny Stripes is greater than this parameter, they will not be merged into a single IO operation. Default is 1M.

- `orc_tiny_stripe_amplification_factor` (3.1.0+)

In Tiny Stripe optimization, if there are many columns in the ORC file but only a few are used in the query, Tiny Stripe optimization may cause severe read amplification. When the proportion of actually read bytes to the entire Stripe exceeds this parameter, Tiny Stripe read optimization will be used. The default value is 0.4, and the minimum value is 0.

- `check_orc_init_sargs_success` (3.1.0+)

Checks whether ORC predicate pushdown is successful, used for debugging. Default is false.

BE Configuration

- `orc_natural_read_size_mb` (2.1+, 3.0+)

The maximum number of bytes that the ORC Reader reads at one time. Default is 8 MB.

Text/CSV/JSON

This document introduces the support for reading and writing text file formats in Doris.

Text/CSV

- Catalog

Supports reading Hive tables in the `org.apache.hadoop.mapred.TextInputFormat` format.

Support following SerDes:

- `org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe`
- `org.apache.hadoop.hive.serde2.OpenCSVSerde` (Since 2.1.7)
- `org.apache.hadoop.hive.serde2.MultiDelimitSerDe` (Since 3.1.0)

- Table Valued Function

- Import

Import functionality supports Text/CSV formats. See the import documentation for details.

- Export

Export functionality supports Text/CSV formats. See the export documentation for details.

Supported Compression Formats

- uncompressed
- gzip
- deflate
- bzip2
- zstd
- lz4
- snappy
- lzo

JSON

Catalog

- `org.apache.hadoop.hive.serde2.JsonSerDe` (Since 3.0.4)
- `org.apache.hive.hcatalog.data.JsonSerDe` (Since 3.0.4)
 1. Supports both primitive and complex types.
 2. Does not support the timestamp formats `SERDEPROPERTIES`.

- Hive table in [org.openx.data.jsonserde.JsonSerDe](#) (Since 3.0.6)
 1. Supports both primitive and complex types.
 2. SERDEPROPERTIES: Only [ignore.malformed.json](#) is supported and behaves the same as in this JsonSerDe. Other SERDEPROPERTIES are not effective.
 3. Does not support [Using Arrays](#) (similar to Text/CSV format, where all column data is placed into a single array).
 4. Does not support [Promoting a Scalar to an Array](#) (promoting a scalar to a single-element array).
 5. By default, Doris can correctly recognize the table schema. However, due to the lack of support for certain parameters, automatic schema recognition might fail. In this case, you can set `read_hive_json_in_one_column = true` to place the entire JSON row into the first column to ensure the original data is fully read. Users can then process it manually. This feature requires the first column's data type to be String.

Import

Import functionality supports JSON formats. See the import documentation for details.

Character Set

Currently, Doris only supports the UTF-8 character set encoding. However, some data, such as the data in Hive Text-formatted tables, may contain content encoded in non-UTF-8 encoding, which will cause reading failures and result in the following error:

```
Only support csv data in utf8 codec
```

In this case, you can set the session variable as follows:

```
SET enable_text_validate_utf8 = false
```

This will ignore the UTF-8 encoding check, allowing you to read this content. Note that this parameter is only used to skip the check, and non-UTF-8 encoded content will still be displayed as garbled text.

This parameter has been supported since version 3.0.4.

Data Cache

Data Cache accelerates subsequent queries of the same data by caching recently accessed data files from remote storage systems (HDFS or object storage) to local disks. In scenarios where the same data is frequently accessed, Data Cache can avoid the overhead of repeated remote data access, improving the performance and stability of query analysis on hot data.

Applicable Scenarios

The data cache function only works for queries on Hive, Iceberg, Hudi, and Paimon tables. It has no effect on internal table queries or non-file external table queries (such as JDBC, Elasticsearch).

Whether data caching can improve query efficiency depends on multiple factors. Below are the applicable scenarios for data caching:

- High-speed local disk

It is recommended to use high-speed local disks, such as SSD or NVME media local disks, as the data cache directory. It is not recommended to use mechanical hard drives as the data cache directory. Essentially, the local disk's IO bandwidth and IOPS must be significantly higher than the network bandwidth and the source storage system's IO bandwidth and IOPS to bring noticeable performance improvements.

- Sufficient cache space size

Data caching uses the LRU strategy as the cache eviction policy. If the queried data does not have a clear distinction between hot and cold, the cached data may be frequently updated and replaced, which may reduce query performance. It is recommended to enable data caching in scenarios where the query pattern has a clear distinction between hot and cold (e.g., most queries only access today's data and rarely access historical data), and the cache space is sufficient to store hot data.

- Unstable IO latency of remote storage

This situation usually occurs on HDFS storage. In most enterprises, different business departments share the same HDFS, which may lead to very unstable IO latency during peak periods. In this case, if you need to ensure stable IO latency, it is recommended to enable data caching. However, the first two conditions should still be considered.

Enabling Data Cache

The data cache function is disabled by default and needs to be enabled by setting relevant parameters in FE and BE.

BE Configuration

First, configure the cache path information in `be.conf` and restart the BE node to make the configuration effective.

| Parameter | Required | Description |
|-------------------|----------|---|
| enable_file_cache | Yes | Whether to enable Data Cache, default is false |
| file_cache_path | Yes | Configuration related to the cache directory, in JSON format. |
| clear_file_cache | No | Default is false. If true, the cache directory will be cleared when the BE node restarts. |

Example configuration of file_cache_path:

```
file_cache_path=[{"path": "/path/to/file_cache1", "total_size":53687091200}, {"path": "/path/to/file_cache2", "total_size":53687091200}, {"path": "/path/to/file_cache3", "total_size":53687091200}]
```

path is the path where the cache is stored, and one or more paths can be configured. It is recommended to configure only one path per disk.

total_size is the upper limit of the cache space size, in bytes. When the cache space is exceeded, the LRU strategy will be used to evict cached data.

FE Configuration

Enable Data Cache in a single session:

```
SET enable_file_cache = true;
```

Enable Data Cache globally:

```
SET GLOBAL enable_file_cache = true;
```

Note that if enable_file_cache is not enabled, the cache will not be used even if the BE is configured with a cache directory. Similarly, if the BE is not configured with a cache directory, the cache will not be used even if enable_file_cache is enabled.

Cache Observability

View Cache Hit Rate

Execute `set enable_profile=true` to open the session variable, and you can view the job's Profile on the Queries tab of the FE web page. The data cache-related metrics are as follows:

```
- FileCache: 0ns
  - BytesScannedFromCache: 2.02 GB
  - BytesScannedFromRemote: 0.00
  - BytesWriteIntoCache: 0.00
  - LocalIOUseTimer: 2s723ms
  - NumLocalIOTotal: 444
  - NumRemoteIOTotal: 0
  - NumSkipCacheIOTotal: 0
```

```
- RemoteIOUseTimer: 0ns
- WriteCacheIOUseTimer: 0ns
```

- BytesScannedFromCache: The amount of data read from the local cache.
- BytesScannedFromRemote: The amount of data read from the remote.
- BytesWriteIntoCache: The amount of data written into the cache.
- LocalIOUseTimer: The IO time of the local cache.
- RemoteIOUseTimer: The IO time of remote reading.
- NumLocalIOTotal: The number of IO operations on the local cache.
- NumRemoteIOTotal: The number of remote IO operations.
- WriteCacheIOUseTimer: The IO time of writing into the cache.

If BytesScannedFromRemote is 0, it means the cache is fully hit.

Monitoring Metrics

Users can view cache statistics for each Backend node through the system table [file cache statistics](#).

Appendix

Principle

Data caching caches accessed remote data to the local BE node. The original data file is split into Blocks based on the accessed IO size, and Blocks are stored in the local file `cache_path/hash(filepath).substr(0, 3)/hash(filepath)/offset`, with Block metadata saved in the BE node. When accessing the same remote file, doris checks whether the cache data of the file exists in the local cache and determines which data to read from the local Block and which data to pull from the remote based on the Block's offset and size, caching the newly pulled remote data. When the BE node restarts, it scans the `cache_path` directory to restore Block metadata. When the cache size reaches the upper limit, it cleans up long-unused Blocks according to the LRU principle.

Metadata Cache

To improve the performance of accessing external data sources, Apache Doris caches the **metadata** of external data sources.

Metadata includes information such as databases, tables, columns, partitions, snapshots, file lists, etc.

This article details the types, strategies, and related parameter configurations of cached metadata.

For **data cache**, refer to the [data cache documentation](#).

This document applies to versions after 2.1.6.

Cache Strategies

Most caches have the following three strategy indicators:

- Maximum cache count

The maximum number of objects the cache can hold. For example, up to 1000 tables can be cached. When the cache count exceeds the threshold, the LRU (Least-Recent-Used) strategy is used to remove some caches.

- Eviction time

- Before version 3.0.6 (inclusive):

After a cache object is written to the cache for a period of time, the object will be automatically removed from the cache. The next access will re-fetch the latest information from the data source and update the cache.

For example, a user first accesses table A at 08:00 and writes it to the cache. If the eviction time is 4 hours, then, unless replaced due to capacity issues, the user will directly access table A in the cache between 08:00-14:00. After 14:00, the cache is evicted. If the user accesses table A again, the latest information will be fetched from the data source and the cache will be updated.

- After version 3.0.7 (inclusive):

Starting from version 3.0.7, this strategy is changed to **the cache object will be automatically removed after being accessed** for a period of time, instead of **after being written** for a period of time. Each time the cache object is accessed, the timer is reset to ensure that frequently accessed objects always remain in the cache.

For example, a user first accesses table A at 08:00 and writes it to the cache. If the eviction time is 4 hours, then, unless replaced due to capacity issues, the user will directly access table A in the cache between 08:00-14:00. Suppose the user accesses this object again at 09:00, then the cache eviction time will be recalculated from 09:00, i.e., it becomes 15:00.

- Minimum refresh time

After a cache object is written to the cache for a period of time, it will automatically trigger a refresh.

For example, a user first accesses table A at 08:00 and writes it to the cache. If the minimum refresh time is 10 minutes, then, unless replaced due to capacity issues, the user will directly access table A in the cache between 08:00-8:10. At 08:10, the cache object will be marked as [ready to refresh]. When the user accesses this cache object again, the current object will still be returned, but the cache refresh operation will be triggered at the same time. Suppose the cache update takes 1 minute, then after 1 minute, accessing the cache again will get the updated cache object.

Note that the time to trigger the cache refresh is [the first access to the cache object after exceeding the minimum refresh time], and it is an asynchronous refresh. So, for example, if the minimum refresh time is 10 minutes, it does not mean that the latest object will be obtained after 10 minutes.

This strategy is different from [eviction time], mainly used to adjust the timeliness of the cache, and avoids blocking the current operation by asynchronously refreshing the cache.

Cache Types

Database and Table Name Lists

The database name list refers to the list of all database names under a Catalog.

The table name list refers to the list of all table names under a database.

The name list is only used for operations that need to enumerate names, such as the SHOW TABLES or SHOW DATABASES statements.

Each Catalog has a database name list cache. Each database has a table name list cache.

- Maximum cache count

Each cache has only one entry. So the maximum cache count is 1.

- Eviction time

Fixed at 86400 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest name list in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Database and Table Objects

Caches individual database and table objects. Any access operation to a database or table, such as query, write, etc., will obtain the corresponding object from this cache.

Note that the list of objects in this cache may be inconsistent with the **database and table name list** cache.

For example, through the `SHOW TABLES` command, you get tables A, B, and C from the name list cache.

Suppose table D is added to the external data source at this time, then `SELECT * FROM D` can access table D, and the [table object] cache will add the table D object, but the [table name list] cache may still be A, B, C. Only when the [table name list] cache is refreshed will it become A, B, C, D.

Each Catalog has a database name list cache. Each database has a table name list cache.

- Maximum cache count

Controlled by the FE configuration item `max_meta_object_cache_num`, default is 1000. You can adjust this parameter appropriately according to the number of databases under a single Catalog or the number of tables under a single database.

- Eviction time

Fixed at 86400 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest database or table in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Table Schema

Caches the schema information of tables, such as column names. This cache is mainly used to load the schema of accessed tables on demand, to prevent synchronizing a large number of unnecessary table schemas and occupying FE memory.

This cache is shared by all Catalogs and is globally unique.

- Maximum cache count

Controlled by the FE configuration item `max_external_schema_cache_num`, default is 10000.

You can adjust this parameter appropriately according to the total number of tables under a Catalog.

- Eviction time

Fixed at 86400 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest schema in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Hive Metastore Table Partition List

Used to cache the partition list of tables synchronized from Hive Metastore. The partition list is used for partition pruning during queries.

This cache, each Hive Catalog has one.

- Maximum cache count

Controlled by the FE configuration item `max_hive_partition_table_cache_num`, default is 1000.

You can adjust this parameter appropriately according to the total number of tables under a Catalog.

- Eviction time

Fixed at 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest partition list in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Hive Metastore Table Partition Properties

Used to cache the properties of each partition of a Hive table, such as file format, partition root path, etc. For each query, after partition pruning to get the list of partitions to be accessed, the detailed properties of each partition are obtained through this cache.

This cache, each Hive Catalog has one.

- Maximum cache count

Controlled by the FE configuration item `max_hive_partition_cache_num`, default is 10000.

You can adjust this parameter appropriately according to the total number of partitions to be accessed under a Catalog.

- Eviction time

Fixed at 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest partition properties in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Hive Metastore Table Partition File List

Used to cache the file list information under a single partition of a Hive table. This cache is used to reduce the overhead of file system List operations.

- Maximum cache count

Controlled by the FE configuration item `max_external_file_cache_num`, default is 100000.

You can adjust this parameter appropriately according to the number of files to be accessed.

- Eviction time

Default is 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

If the `file.meta.cache.ttl-second` property is set in the Catalog properties, the set time is used.

In some cases, the data files of Hive tables change frequently, resulting in the cache not meeting timeliness requirements. You can set this parameter to 0 to disable this cache. In this case, the file list will be obtained in real time for each query, which may reduce performance but improve file timeliness.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest partition properties in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Hudi Table Partitions

Used to cache partition information of Hudi tables.

This cache, each Hudi Catalog has one.

- Maximum cache count

Controlled by the FE configuration item `max_external_table_cache_num`, default is 1000.

You can adjust this parameter appropriately according to the number of Hudi tables.

- Eviction time

Fixed at 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest Hudi partition properties in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Iceberg Table Information

Used to cache Iceberg table objects. The object is loaded and constructed through the Iceberg API.

This cache, each Iceberg Catalog has one.

- Maximum cache count

Controlled by the FE configuration item `max_external_table_cache_num`, default is 1000.

You can adjust this parameter appropriately according to the number of Iceberg tables.

- Eviction time

Fixed at 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest Iceberg table properties in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Iceberg Table Snapshot

Used to cache the snapshot list of Iceberg tables. The object is loaded and constructed through the Iceberg API. This cache, each Iceberg Catalog has one.

- Maximum cache count

Controlled by the FE configuration item `max_external_table_cache_num`, default is 1000.

You can adjust this parameter appropriately according to the number of Iceberg tables.

- Eviction time

Fixed at 28800 seconds. After version 3.0.7, configured by the FE parameter `external_cache_expire_time_seconds_after_access`, default is 86400 seconds.

- Minimum refresh time

Controlled by the FE configuration item `external_cache_expire_time_minutes_after_access`, in minutes. Default is 10 minutes. Reducing this time allows you to see the latest Iceberg table properties in Doris more in real time, but increases the frequency of accessing external data sources.

After version 3.0.7, the configuration item name is changed to `external_cache_refresh_time_minutes`. The default value remains unchanged.

Cache Refresh

In addition to the refresh and eviction strategies of each cache above, users can also directly refresh the metadata cache manually or on a schedule.

Manual Refresh

Users can manually refresh metadata using the REFRESH command.

1. REFRESH CATALOG

Refresh the specified Catalog.

```
REFRESH CATALOG ctl1 PROPERTIES("invalid_cache" = "true");
```

- This command refreshes the database list, table column names, and all cache information of the specified Catalog.
- `invalid_cache` indicates whether to refresh caches such as partitions and file lists. The default is true. If false, only the database and table lists of the Catalog will be refreshed, but not caches such as partitions and file lists. This parameter is suitable for cases where the user only wants to synchronize newly added or deleted databases and tables, and can be set to false.

2. REFRESH DATABASE

Refresh the specified Database.

```
REFRESH DATABASE [ctl.]db1 PROPERTIES("invalid_cache" = "true");
```

- This command refreshes the table column names and all cache information under the specified Database.
- The meaning of the `invalid_cache` property is the same as above. The default is true. If false, only the table list of the Database will be refreshed, but not the cache information. This parameter is suitable for cases where the user only wants to synchronize newly added or deleted tables.

3. REFRESH TABLE

Refresh the specified Table.

```
REFRESH TABLE [ctl.][db.]tbl1;
```

- This command refreshes all cache information under the specified Table.

Scheduled Refresh

Users can set up scheduled refreshes for a Catalog when creating it.

```
CREATE CATALOG hive PROPERTIES (  
  'type'='hms',  
  'hive.metastore.uris' = 'thrift://172.0.0.1:9083',  
  'metadata_refresh_interval_sec' = '3600'  
);
```

In the above example, `metadata_refresh_interval_sec` means the Catalog is refreshed every 3600 seconds. This is equivalent to automatically executing once every 3600 seconds:

```
REFRESH CATALOG ctl1 PROPERTIES("invalid_cache" = "true");
```

Best Practices

Caching can significantly improve metadata access performance and avoid frequent remote access to metadata, which can cause performance jitter or put pressure on the metadata service. However, caching also reduces data timeliness. For example, if the cache refresh time is 10 minutes, only cached metadata can be read within ten minutes. Therefore, it is necessary to set the cache reasonably according to the situation.

Default Behavior

This section mainly introduces the cache behavior that users may be concerned about under the default parameter configuration.

- After a new database or table is added to the external data source, it can be queried in real time in Doris through SELECT. But SHOW DATABASES and SHOW TABLES may not see it; you need to manually refresh the cache or wait up to 10 minutes.
- When a new partition is added to the external data source, you need to manually refresh the cache or wait up to 10 minutes to query the new partition data.
- When partition data files change, you need to manually refresh the cache or wait up to 10 minutes to query the new partition data.

Disable Schema Cache

For all types of External Catalogs, if you want to see the latest Table Schema in real time, you can disable the Schema Cache:

- Disable globally

```
-- fe.conf  
max_external_schema_cache_num=0 // Disable Schema cache.
```

- Disable at Catalog level

```
-- Catalog property
"schema.cache.ttl-second" = "0" // For a specific Catalog, disable Schema cache (supported in 2.1.11, 3.0.6)
```

After setting, Doris will see the latest Table Schema in real time. However, this setting may increase the pressure on the metadata service.

Disable Hive Catalog Metadata Cache

For Hive Catalog, if you want to disable the cache to query real-time updated data, you can configure the following parameters:

- Disable globally

```
-- fe.conf
max_external_file_cache_num=0    // Disable file list cache
max_hive_partition_table_cache_num=0 // Disable partition list cache
```

- Disable at Catalog level

```
-- Catalog property
"file.meta.cache.ttl-second" = "0" // For a specific Catalog, disable file list cache
"partition.cache.ttl-second" = "0" // For a specific Catalog, disable partition list cache (supported in 2.1.11, 3.0.6)
```

After setting the above parameters:

- New partitions in the external data source can be queried in real time.
- Changes in partition data files can be queried in real time.

But this will increase the access pressure on external data sources (such as Hive Metastore and HDFS), which may cause unstable metadata access latency and other phenomena.

Elastic Compute Node

Elastic compute nodes, as a special type of BE node, do not have data storage capabilities and are only responsible for data computation. Therefore, compute nodes can be regarded as stateless BE nodes, which can be easily added and removed.

In lakehouse data analysis scenarios, elastic compute nodes can be used to query external data sources such as Hive, Iceberg, Hudi, Paimon, JDBC, etc. Doris does not handle the storage of external data source data, so elastic compute nodes can be used to easily expand the computing power for external data sources. Additionally, compute nodes can also be configured with cache directories to cache hot data from external data sources, further accelerating data reading.

Elastic compute nodes **are suitable for elastic resource control in the integrated storage and computing mode of Doris**. In the storage-compute separation architecture of Doris 3.0, BE nodes are stateless, so separate elastic compute nodes are no longer needed.

Usage of Compute Nodes

BE Node Types

In the integrated storage and computing mode, BE nodes are divided into two types:

- Mix

Mixed nodes. This is the default type of BE node. These nodes participate in both computation and the storage of Doris internal table data.

- Computation

Elastic compute nodes. They do not handle data storage, only data computation.

Adding Compute Nodes

Add the following configuration in the BE `be.conf` configuration file:

```
be_node_role=computation
```

Afterwards, start the BE node, and it will run as a Computation type.

Then you can connect to Doris and execute:

```
ALTER SYSTEM ADD BACKEND
```

to add this BE node. Once added successfully, you can see the node type as `computation` in the `NodeRole` column of `SHOW BACKENDS`.

Using Compute Nodes

You need to configure the following parameters in the FE configuration file `fe.conf` to enable compute nodes and control their behavior:

| Parameter Name | Description |
|---|---|
| <code>prefer_compute_node_for_external_table</code> | Default is <code>false</code> . If set to <code>true</code> , queries for external tables will be preferentially assigned to compute nodes. If <code>false</code> , queries for external tables will be assigned to any BE node. If there are no compute nodes in the cluster, this parameter has no effect. |
| <code>min_backend_num_for_external_table</code> | Only effective when <code>prefer_compute_node_for_external_table</code> is <code>true</code> . If the number of compute nodes in the cluster is less than this value, queries for external tables will attempt to acquire some mixed nodes to allocate, so that the total number of nodes reaches this value. If the number of compute nodes in the cluster is greater than this value, queries for external tables will only be assigned to compute nodes. Before version 2.0 (inclusive), the default value of this parameter was 3. After version 2.1, the default value is <code>-1</code> , which means only the current number of compute nodes will be used. |

Further explanation of `min_backend_num_for_external_table`:

Assume there are 3 compute nodes and 5 mixed nodes in the cluster.

If `min_backend_num_for_external_table` is set to less than or equal to 3, then external table queries will only use 3 compute nodes. If set to greater than 3, say 6, then external table queries will use 3 compute nodes plus an additional 3 mixed nodes for computation.

In summary, this parameter is mainly used for the minimum number of BE nodes that can participate in external table computation, and will preferentially select compute nodes. Increasing this parameter will allow more BE nodes (not limited to compute nodes) to participate in external table query processing; decreasing this parameter can limit the number of BE nodes participating in external table query processing.

Note:

1. After version 2.1, `min_backend_num_for_external_table` can be set to `-1`. In previous versions, this parameter must be a positive number. This parameter is only effective when `prefer_compute_node_for_external_table = true`.
2. If the value of `min_backend_num_for_external_table` is greater than the total number of BE nodes, at most all BEs will be selected.
3. The above parameters can be dynamically modified using the `ADMIN SET FRONTEND CONFIG` command without restarting the FE node. All FE nodes need to be configured. Alternatively, add the configuration in `fe.conf` and restart the FE node.

Best Practices

Resource Isolation and Elastic Scaling of Federated Queries

In federated query scenarios, users can deploy a dedicated set of compute nodes for querying external table data. This allows the isolation of external table query loads (such as large-scale analysis on Hive) from internal

table query loads (such as low-latency fast data analysis).

At the same time, as stateless BE nodes, compute nodes can be easily scaled up and down. For example, a set of elastic compute node clusters can be deployed using k8s, utilizing more compute nodes for data lake analysis during peak business periods, and quickly scaling down during off-peak periods to reduce costs.

Common Issues

1. Can mixed nodes and compute nodes be converted to each other?

Compute nodes can be converted to mixed nodes. However, mixed nodes cannot be converted to compute nodes.

2. Do compute nodes need to configure data storage directories?

Yes. The data storage directory of compute nodes will not store user data, only some information files of the BE node itself, such as `cluster_id`, and some temporary files during operation.

The storage directory of compute nodes requires only a small amount of disk space (MB level) and can be destroyed at any time along with the node without affecting user data.

3. Can compute nodes and mixed nodes configure file cache directories?

[File cache](#) accelerates subsequent queries of the same data by caching data files from recently accessed remote storage systems (HDFS or object storage).

Both compute nodes and mixed nodes can set up file cache directories. The file cache directory needs to be created in advance.

4. Do compute nodes need to be decommissioned through the DECOMMISSION operation?

No. Compute nodes can be directly deleted using the `DROP BACKEND` operation.

Statistics | Lakehouse

Statistics

Doris supports automatic or manual statistics collection for tables from external data sources like Hive, Iceberg and Paimon. The accuracy of statistics directly determines the accuracy of cost estimation, which is crucial for selecting the optimal query plan. This can significantly improve query execution efficiency, especially in complex query scenarios.

For details, please refer to the [Statistics](#) document in the “External Table Collection” section.

Data Lake Query Optimization

This document mainly introduces optimization methods and strategies for querying lake data (Hive, Iceberg, Paimon, etc.).

Partition Pruning

By specifying partition column conditions in queries, unnecessary partitions can be pruned, reducing the amount of data that needs to be read.

You can use `EXPLAIN <SQL>` to view the `partition` section of `XXX_SCAN_NODE` to check whether partition pruning is effective and how many partitions need to be scanned in this query.

For example:

```
0:VPAIMON_SCAN_NODE(88)
  table: paimon_ctl.db.table
  predicates: (user_id[#4] = 431304818)
  inputSplitNum=15775, totalFileSize=951754154566, scanRanges=15775
  partition=203/0
```

Local Data Cache

Data Cache accelerates subsequent queries accessing the same data by caching recently accessed data files from remote storage systems (HDFS or object storage) to local disk.

The cache feature is disabled by default. Please refer to the [Data Cache](#) documentation to configure and enable it.

Since version 4.0.2, cache warmup functionality is supported, which can further actively utilize data cache to improve query performance.

HDFS Read Optimization

Please refer to the **HDFS IO Optimization** section in the [HDFS Documentation](#).

Merge IO Optimization

For remote storage systems like HDFS and object storage, Doris optimizes IO access through Merge IO technology. Merge IO technology essentially merges multiple adjacent small IO requests into one large IO request, which can reduce IOPS and increase IO throughput.

For example, if the original request needs to read parts `[0, 10]` and `[20, 50]` of file `file1`:

```
Request Range: [0, 10], [20, 50]
```

Through Merge IO, it will be merged into one request:

```
Request Range: [0, 50]
```

In this example, two IO requests are merged into one, but it also reads some additional data (data between 10-20). Therefore, while Merge IO reduces the number of IO operations, it may bring potential read amplification issues.

You can view specific Merge IO information through Query Profile:

```
- MergedSmallIO:
  - MergedBytes: 3.00 GB
  - MergedIO: 424
  - RequestBytes: 2.50 GB
  - RequestIO: 65.555K (65555)
```

Where RequestBytes and RequestIO indicate the data volume and number of requests in the original request. MergedBytes and MergedIO indicate the data volume and number of requests after merging.

If you find that MergedBytes is much larger than RequestBytes, it indicates serious read amplification. You can adjust it through the following parameters:

- `merge_io_read_slice_size_bytes`

Session variable, supported since version 3.1.3. Default is 8MB. If you find serious read amplification, you can reduce this parameter, such as to 64KB, and observe whether the modified IO requests and query latency improve.

Using Doris and Hudi

As a new open data management architecture, the Data Lakehouse integrates the high performance and real-time capabilities of data warehouses with the low cost and flexibility of data lakes, helping users more conveniently meet various data processing and analysis needs. It has been increasingly applied in enterprise big data systems.

In recent versions, Apache Doris has deepened its integration with data lakes and has evolved a mature Data Lakehouse solution.

- Since version 0.15, Apache Doris has introduced Hive and Iceberg external tables, exploring the capabilities of combining with Apache Iceberg for data lakes.
- Starting from version 1.2, Apache Doris officially introduced the Multi-Catalog feature, enabling automatic metadata mapping and data access for various data sources, along with numerous performance optimizations for external data reading and query execution. It now fully possesses the ability to build a high-speed and user-friendly Lakehouse architecture.
- In version 2.1, Apache Doris' Data Lakehouse architecture was significantly enhanced, improving the reading and writing capabilities of mainstream data lake formats (Hudi, Iceberg, Paimon, etc.), introducing compatibility with multiple SQL dialects, and seamless migration from existing systems to Apache Doris. For data science and large-scale data reading scenarios, Doris integrated the Arrow Flight high-speed reading interface, achieving a 100-fold increase in data transfer efficiency.

Building lakehouse using doris and hudi

Apache Doris & Hudi

[Apache Hudi](#) is currently one of the most popular open data lake formats and a transactional data lake management platform, supporting various mainstream query engines including Apache Doris.

Apache Doris has also enhanced its ability to read Apache Hudi data tables:

- Supports Copy on Write Table: Snapshot Query
- Supports Merge on Read Table: Snapshot Queries, Read Optimized Queries
- Supports Time Travel
- Supports Incremental Read

With Apache Doris' high-performance query execution and Apache Hudi's real-time data management capabilities, efficient, flexible, and cost-effective data querying and analysis can be achieved. It also provides robust data lineage, auditing, and incremental processing functionalities. The combination of Apache Doris and Apache Hudi has been validated and promoted in real business scenarios by multiple community users:

- Real-time data analysis and processing: Common scenarios such as real-time data updates and query analysis in industries like finance, advertising, and e-commerce require real-time data processing. Hudi enables real-time data updates and management while ensuring data consistency and reliability. Doris efficiently handles large-scale data query requests in real-time, meeting the demands of real-time data analysis and processing effectively when combined.
- Data lineage and auditing: For industries with high requirements for data security and accuracy like finance and healthcare, data lineage and auditing are crucial functionalities. Hudi offers Time Travel functionality for viewing historical data states, combined with Apache Doris' efficient querying capabilities, enabling quick analysis of data at any point in time for precise lineage and auditing.
- Incremental data reading and analysis: Large-scale data analysis often faces challenges of large data volumes and frequent updates. Hudi supports incremental data reading, allowing users to process only the changed data without full data updates. Additionally, Apache Doris' Incremental Read feature enhances this process, significantly improving data processing and analysis efficiency.
- Cross-data source federated queries: Many enterprises have complex data sources stored in different databases. Doris' Multi-Catalog feature supports automatic mapping and synchronization of various data sources, enabling federated queries across data sources. This greatly shortens the data flow path and enhances work efficiency for enterprises needing to retrieve and integrate data from multiple sources for analysis.

This article will introduce readers to how to quickly set up a test and demonstration environment for Apache Doris + Apache Hudi in a Docker environment, and demonstrate various operations to help readers get started quickly.

For more information, please refer to [Hudi Catalog](#)

User Guide

All scripts and code mentioned in this article can be obtained from this address:

<https://github.com/apache/doris/tree/master/samples/datalake/hudi>

01 Environment Preparation

This article uses Docker Compose for deployment, with the following components and versions:

| Component | Version |
|--------------|--------------------------------|
| Apache Doris | Default 2.1.4, can be modified |
| Apache Hudi | 0.14 |

| Component | Version |
|--------------|----------------------|
| Apache Spark | 3.4.2 |
| Apache Hive | 2.1.3 |
| MinIO | 2022-05-26T05-48-41Z |

02 Environment Deployment

1. Create a Docker network

```
sudo docker network create -d bridge hudi-net
```

2. Start all components

```
sudo ./start-hudi-compose.sh
```

Note: Before starting, you can modify the `DORIS_PACKAGE` and `DORIS_DOWNLOAD_URL` in `start-hudi-compose.sh` to the desired Doris version. It is recommended to use version 2.1.4 or higher.

3. After starting, you can use the following script to log in to Spark command line or Doris command line:

```
-- Spark
sudo ./login-spark.sh

-- Doris
sudo ./login-doris.sh
```

03 Data Preparation

Next, generate Hudi data through Spark. As shown in the code below, there is already a Hive table named `customer` in the cluster. You can create a Hudi table using this Hive table:

```
-- ./login-spark.sh
spark-sql> use default;

-- create a COW table
spark-sql> CREATE TABLE customer_cow
USING hudi
TBLPROPERTIES (
  type = 'cow',
  primaryKey = 'c_custkey',
  preCombineField = 'c_name'
)
PARTITIONED BY (c_nationkey)
AS SELECT * FROM customer;

-- create a MOR table
spark-sql> CREATE TABLE customer_mor
USING hudi
TBLPROPERTIES (
  type = 'mor',
  primaryKey = 'c_custkey',
  preCombineField = 'c_name'
```

```
)
PARTITIONED BY (c_nationkey)
AS SELECT * FROM customer;
```

04 Data Query

As shown below, a Catalog named hudi has been created in the Doris cluster (can be viewed using SHOW CATALOGS). The following is the creation statement for this Catalog:

```
-- Already created, no need to execute again
CREATE CATALOG `hudi` PROPERTIES (
  "type"="hms",
  'hive.metastore.uris' = 'thrift://hive-metastore:9083',
  "s3.access_key" = "minio",
  "s3.secret_key" = "minio123",
  "s3.endpoint" = "http://minio:9000",
  "s3.region" = "us-east-1",
  "use_path_style" = "true"
);
```

1. Manually refresh this Catalog to synchronize the created Hudi table:

```
-- ./login-doris.sh
doris> REFRESH CATALOG hudi;
```

2. Operations on data in Hudi using Spark are immediately visible in Doris without the need to refresh the Catalog. We insert a row of data into both COW and MOR tables using Spark:

```
spark-sql> insert into customer_cow values (100, "Customer#0000000100", "jD2xZzi", "25-430-914-2194",
3471.59, "BUILDING", "cial ideas. final, furious requests", 25);
spark-sql> insert into customer_mor values (100, "Customer#0000000100", "jD2xZzi", "25-430-914-2194",
3471.59, "BUILDING", "cial ideas. final, furious requests", 25);
```

3. Through Doris, you can directly query the latest inserted data:

```
doris> use hudi.default;
doris> select * from customer_cow where c_custkey = 100;
doris> select * from customer_mor where c_custkey = 100;
```

4. Insert data with c_custkey=32 that already exists using Spark, thus overwriting the existing data:

```
spark-sql> insert into customer_cow values (32, "Customer#000000032_update", "jD2xZzi", "25-430-914-
2194", 3471.59, "BUILDING", "cial ideas. final, furious requests", 15);
spark-sql> insert into customer_mor values (32, "Customer#000000032_update", "jD2xZzi", "25-430-914-
2194", 3471.59, "BUILDING", "cial ideas. final, furious requests", 15);
```

5. With Doris, you can query the updated data:

```
doris> select * from customer_cow where c_custkey = 32;
+-----+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address | c_phone | c_acctbal | c_mktsegment |
| c_comment | c_nationkey |
```

```

+-----+-----+-----+-----+-----+-----+-----+
|      32 | Customer#000000032_update | jD2xZzi | 25-430-914-2194 | 3471.59 | BUILDING | cial ideas. final, furious requests | 15 |
+-----+-----+-----+-----+-----+-----+-----+

doris> select * from customer_mor where c_custkey = 32;

+-----+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address | c_phone          | c_acctbal | c_mktsegment | c_comment          |
| c_nationkey | c_nationkey |
+-----+-----+-----+-----+-----+-----+-----+

|      32 | Customer#000000032_update | jD2xZzi | 25-430-914-2194 | 3471.59 | BUILDING | cial ideas. final, furious requests | 15 |
+-----+-----+-----+-----+-----+-----+-----+

```

05 Incremental Read

Incremental Read is one of the features provided by Hudi. With Incremental Read, users can obtain incremental data within a specified time range, enabling incremental processing of data. In this regard, Doris can query the changed data after inserting `c_custkey=100`. As shown below, we inserted a data with `c_custkey=32`:

```

doris> select * from customer_cow@incr('beginTime'='20240603015018572');

+-----+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address | c_phone          | c_acctbal | c_mktsegment | c_comment          |
| c_nationkey |
+-----+-----+-----+-----+-----+-----+-----+

|      32 | Customer#000000032_update | jD2xZzi | 25-430-914-2194 | 3471.59 | BUILDING | cial ideas. final, furious requests | 15 |
+-----+-----+-----+-----+-----+-----+-----+

spark-sql> select * from hudi_table_changes('customer_cow', 'latest_state', '20240603015018572');

doris> select * from customer_mor@incr('beginTime'='20240603015058442');

+-----+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address | c_phone          | c_acctbal | c_mktsegment | c_comment          |
| c_nationkey |
+-----+-----+-----+-----+-----+-----+-----+

|      32 | Customer#000000032_update | jD2xZzi | 25-430-914-2194 | 3471.59 | BUILDING | cial ideas. final, furious requests | 15 |
+-----+-----+-----+-----+-----+-----+-----+

spark-sql> select * from hudi_table_changes('customer_mor', 'latest_state', '20240603015058442');

```

06 TimeTravel

Doris supports querying specific snapshot versions of Hudi data, thereby enabling Time Travel functionality for data. First, you can query the commit history of two Hudi tables using Spark:

```

spark-sql> call show_commits(table => 'customer_cow', limit => 10);
20240603033556094      20240603033558249      commit      448833      0      1      1      183

```

```

0      0
20240603015444737      20240603015446588      commit      450238      0      1      1      202
1      0
20240603015018572      20240603015020503      commit      436692      1      0      1      1
0      0
20240603013858098      20240603013907467      commit      44902033      100      0      25
18751      0      0

spark-sql> call show_commits(table => 'customer_mor', limit => 10);
20240603033745977      20240603033748021      deltacommit      1240      0      1      1      0
0      0
20240603015451860      20240603015453539      deltacommit      1434      0      1      1      1
1      0
20240603015058442      20240603015100120      deltacommit      436691      1      0      1
1      0      0
20240603013918515      20240603013922961      deltacommit      44904040      100      0      25
18751      0      0

```

Next, using Doris, you can execute `c_custkey=32` to query the data snapshot before the data insertion. As shown below, the data with `c_custkey=32` has not been updated yet:

Note: Time Travel syntax is currently not supported by the new optimizer. You need to first execute `set enable_nereids_planner=false;` to disable the new optimizer. This issue will be fixed in future versions.

```

doris> select * from customer_cow for time as of '20240603015018572' where c_custkey = 32 or c_custkey = 100;
+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address          | c_phone          | c_acctbal |
| c_mktsegment | c_comment          | c_nationkey |
+-----+-----+-----+-----+-----+-----+
|      32 | Customer#000000032 | jD2xZzi UmId,DCtNBLXKj9q0Tlp2iQ6Zc03J | 25-430-914-2194 | 3471.53 |
BUILDING | cial ideas. final, furious requests across the e | 15 |
|      100 | Customer#0000000100 | jD2xZzi          | 25-430-914-2194 | 3471.59 |
BUILDING | cial ideas. final, furious requests          | 25 |
+-----+-----+-----+-----+-----+-----+
-- compare with spark-sql
spark-sql> select * from customer_mor timestamp as of '20240603015018572' where c_custkey = 32 or c_custkey = 100;

doris> select * from customer_mor for time as of '20240603015058442' where c_custkey = 32 or c_custkey = 100;
+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name          | c_address          | c_phone          | c_acctbal |
| c_mktsegment | c_comment          | c_nationkey |
+-----+-----+-----+-----+-----+-----+
|      100 | Customer#0000000100 | jD2xZzi          | 25-430-914-2194 | 3471.59 |
BUILDING | cial ideas. final, furious requests          | 25 |
|      32 | Customer#0000000032 | jD2xZzi UmId,DCtNBLXKj9q0Tlp2iQ6Zc03J | 25-430-914-2194 | 3471.53 |
BUILDING | cial ideas. final, furious requests across the e | 15 |
+-----+-----+-----+-----+-----+-----+
spark-sql> select * from customer_mor timestamp as of '20240603015058442' where c_custkey = 32 or c_custkey = 100;

```

Query Optimization

Data in Apache Hudi can be roughly divided into two categories - baseline data and incremental data. Baseline data is typically merged Parquet files, while incremental data refers to data increments generated by INSERT, UPDATE, or DELETE operations. Baseline data can be read directly, while incremental data needs to be read through Merge on Read.

For querying Hudi COW tables or Read Optimized queries on MOR tables, the data belongs to baseline data and can be directly read using Doris' native Parquet Reader, providing fast query responses. For incremental data, Doris needs to access Hudi's Java SDK through JNI calls. To achieve optimal query performance, Apache Doris divides the data in a query into baseline and incremental data parts and reads them using the aforementioned methods.

To verify this optimization approach, we can use the EXPLAIN statement to see how many baseline and incremental data are present in a query example below. For a COW table, all 101 data shards are baseline data (hudiNativeReadSplits=101/101), so the COW table can be entirely read directly using Doris' Parquet Reader, resulting in the best query performance. For a ROW table, most data shards are baseline data (hudiNativeReadSplits=100/101), with one shard being incremental data, which also provides good query performance.

```
-- COW table is read natively
doris> explain select * from customer_cow where c_custkey = 32;
| 0:VHUDI_SCAN_NODE(68) |
| table: customer_cow |
| predicates: (c_custkey[#5] = 32) |
| inputSplitNum=101, totalFileSize=45338886, scanRanges=101 |
| partition=26/26 |
| cardinality=1, numNodes=1 |
| pushdown agg=NONE |
| hudiNativeReadSplits=101/101 |

-- MOR table: because only the base file contains `c_custkey = 32` that is updated, 100 splits are read
natively, while the split with log file is read by JNI.
doris> explain select * from customer_mor where c_custkey = 32;
| 0:VHUDI_SCAN_NODE(68) |
| table: customer_mor |
| predicates: (c_custkey[#5] = 32) |
| inputSplitNum=101, totalFileSize=45340731, scanRanges=101 |
| partition=26/26 |
| cardinality=1, numNodes=1 |
| pushdown agg=NONE |
| hudiNativeReadSplits=100/101 |
```

You can further observe the changes in Hudi baseline data and incremental data by performing some deletion operations using Spark:

```
-- Use delete statement to see more differences
spark-sql> delete from customer_cow where c_custkey = 64;
doris> explain select * from customer_cow where c_custkey = 64;

spark-sql> delete from customer_mor where c_custkey = 64;
doris> explain select * from customer_mor where c_custkey = 64;
```

Additionally, you can reduce the data volume further by using partition conditions for partition pruning to improve query speed. In the example below, partition pruning is done using the partition condition

c_nationkey=15, allowing the query request to access data from only one partition (partition=1/26).

```
-- customer_xxx is partitioned by c_nationkey, we can use the partition column to prune data
doris> explain select * from customer_mor where c_custkey = 64 and c_nationkey = 15;
| 0:VHUDI_SCAN_NODE(68) |
| table: customer_mor |
| predicates: (c_custkey[#5] = 64), (c_nationkey[#12] = 15) |
| inputSplitNum=4, totalFileSize=1798186, scanRanges=4 |
| partition=1/26 |
| cardinality=1, numNodes=1 |
| pushdown agg=NONE |
| hudiNativeReadSplits=3/4 |
```

Using Doris and Paimon

As a new open data management architecture, the Data Lakehouse integrates the high performance and real-time capabilities of data warehouses with the low cost and flexibility of data lakes, helping users more conveniently meet various data processing and analysis needs. It has been increasingly applied in enterprise big data systems.

In recent versions, Apache Doris has deepened its integration with data lakes and has evolved a mature Data Lakehouse solution.

- Since version 0.15, Apache Doris has introduced Hive and Iceberg external tables, exploring the capabilities of combining with Apache Iceberg for data lakes.
- Starting from version 1.2, Apache Doris officially introduced the Multi-Catalog feature, achieving automatic metadata mapping and data access for various data sources, along with many performance optimizations for external data reading and query execution. It now fully possesses the ability to build a high-speed and user-friendly Lakehouse architecture.
- In version 2.1, Apache Doris' Data Lakehouse architecture was significantly enhanced, strengthening the reading and writing capabilities of mainstream data lake formats (Hudi, Iceberg, Paimon, etc.), introducing compatibility with multiple SQL dialects, and seamless migration from existing systems to Apache Doris. For data science and large-scale data reading scenarios, Doris integrated the Arrow Flight high-speed reading interface, achieving a 100-fold improvement in data transfer efficiency.

Building lakehouse using Doris and Paimon

Apache Doris & Paimon

Apache Paimon is a data lake format that innovatively combines the advantages of data lake formats and LSM structures, successfully introducing efficient real-time streaming update capabilities into data lake architecture.

This enables Paimon to efficiently manage data and perform real-time analysis, providing strong support for building real-time Data Lakehouse architecture.

To fully leverage Paimon's capabilities and improve query efficiency for Paimon data, Apache Doris provides native support for several of Paimon's latest features:

- Supports various types of Paimon Catalogs such as Hive Metastore and FileSystem.
- Native support for Paimon 0.6's Primary Key Table Read Optimized feature.
- Native support for Paimon 0.8's Primary Key Table Deletion Vector feature.

With Apache Doris' high-performance query engine and Apache Paimon's efficient real-time streaming update capabilities, users can achieve:

- Real-time data ingestion into the lake: Leveraging Paimon's LSM-Tree model, data ingestion into the lake can be reduced to a minute-level timeliness. Additionally, Paimon supports various data update capabilities including aggregation, deduplication, and partial column updates, making data flow more flexible and efficient.
- High-performance data processing and analysis: Paimon's technologies such as Append Only Table, Read Optimized, and Deletion Vector can be seamlessly integrated with Doris' powerful query engine, enabling fast querying and analysis responses for lake data.

In the future, Apache Doris will gradually support more advanced features of Apache Paimon, including Time Travel and incremental data reading, to jointly build a unified, high-performance, real-time lakehouse platform.

This article will explain how to quickly set up an Apache Doris + Apache Paimon testing & demonstration environment in a Docker environment and demonstrate the usage of various features.

For more information, please refer to [Paimon Catalog](#)

User Guide

All scripts and code mentioned in this article can be obtained from the following address:
https://github.com/apache/doris/tree/master/samples/datalake/iceberg_and_paimon

01 Environment Preparation

This article uses Docker Compose for deployment, with the following components and versions:

| Component | Version |
|---------------|--------------------------------|
| Apache Doris | Default 2.1.5, can be modified |
| Apache Paimon | 0.8 |
| Apache Flink | 1.18 |
| MinIO | RELEASE.2024-04-29T09-56-05Z |

02 Environment Deployment

1. Start all components

```
bash ./start_all.sh
```

2. After starting, you can use the following scripts to log in to the Flink command line or Doris command line:

```
-- login flink
bash ./start_flink_client.sh

-- login doris
bash ./start_doris_client.sh
```

03 Data Preparation

After logging into the Flink command line, you can see a pre-built table. The table already contains some data that can be viewed using Flink SQL.

```
Flink SQL> use paimon.db_paimon;
[INFO] Execute statement succeed.

Flink SQL> show tables;
+-----+
| table name |
+-----+
| customer |
+-----+
1 row in set

Flink SQL> show create table customer;
+-----+
| result |
+-----+
| CREATE TABLE `paimon`.`db_paimon`.`customer` (
  `c_custkey` INT NOT NULL,
  `c_name` VARCHAR(25),
  `c_address` VARCHAR(40),
  `c_nationkey` INT NOT NULL,
  `c_phone` CHAR(15),
  `c_acctbal` DECIMAL(12, 2),
  `c_mktsegment` CHAR(10),
  `c_comment` VARCHAR(117),
  CONSTRAINT `PK_c_custkey_c_nationkey` PRIMARY KEY (`c_custkey`, `c_nationkey`) NOT ENFORCED
) PARTITIONED BY (`c_nationkey`)

04 Data Query

As shown below, a Catalog named paimon has been created in the Doris cluster (can be viewed using SHOW CATALOGS). The following is the statement for creating this Catalog:

```

-- Already created, no need to run
CREATE CATALOG `paimon` PROPERTIES (
  "type" = "paimon",
  "warehouse" = "s3://warehouse/wh/",
  "s3.endpoint"="http://minio:9000",
  "s3.access_key"="admin",
  "s3.secret_key"="password",
  "s3.region"="us-east-1"
);

```

You can query Paimon's data in Doris:

```

mysql> use paimon.db_paimon;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
mysql> show tables;
+-----+
| Tables_in_db_paimon |
+-----+
| customer             |
+-----+
1 row in set (0.00 sec)

mysql> select * from customer order by c_custkey limit 4;
+-----+-----+-----+-----+-----+-----+
| c_custkey | c_name | c_address | c_nationkey | c_phone |
+-----+-----+-----+-----+-----+

```

```

c_acctbal | c_mktsegment | c_comment
|

05 Read Incremental Data

You can update the data in the Paimon table using Flink SQL:

```

Flink SQL> update customer set c_address='c_address_update' where c_nationkey = 1;
[INFO] Submitting SQL update statement to the cluster...
[INFO] SQL update statement has been successfully submitted to the cluster:
Job ID: ff838b7b778a94396b332b0d93c8f7ac

```

After the Flink SQL execution is complete, you can directly view the latest data in Doris:

```

mysql> select * from customer where c_nationkey=1 limit 2;
+-----+-----+-----+-----+-----+-----+-----+
+-----+
| c_custkey | c_name          | c_address          | c_nationkey | c_phone          | c_acctbal | c_mktsegment |
| c_comment |
+-----+-----+-----+-----+-----+-----+-----+

```

Benchmark

We conducted a simple test on the TPCDS 1000 dataset in Paimon (0.8) version, using Apache Doris 2.1.5 version and Trino 422 version, both with the Primary Key Table Read Optimized feature enabled.

From the test results, it can be seen that Doris' average query performance on the standard static test set is 3-5 times that of Trino. In the future, we will optimize the Deletion Vector to further improve query efficiency in real business scenarios.

Query Optimization

For baseline data, after introducing the Primary Key Table Read Optimized feature in Apache Paimon version 0.6, the query engine can directly access the underlying Parquet/ORC files, significantly improving the reading efficiency of baseline data. For unmerged incremental data (data increments generated by INSERT, UPDATE, or DELETE), they can be read through Merge-on-Read. In addition, Paimon introduced the Deletion Vector feature in version 0.8, which further enhances the query engine's efficiency in reading incremental data. Apache Doris supports reading Deletion Vector through native Reader and performing Merge on Read. We demonstrate the query methods for baseline data and incremental data in a query using Doris' EXPLAIN statement.

```
mysql> explain verbose select * from customer where c_nationkey < 3;
```

```
+-----+
| Explain String(Nereids Planner)
|
+-----+
| .....
|
| 0:VPAIMON_SCAN_NODE(68)
|
|   table: customer
|
|   predicates: (c_nationkey[#3] < 3)
|
|   inputSplitNum=4, totalFileSize=238324, scanRanges=4
|
|   partition=3/0
|
|   backends:
```

```

|
|      10002
|
|      s3://warehouse/wh/db_paimon.db/customer/c_nationkey=1/bucket-0/data-15cee5b7-1bd7-42ca-9314-

|      s3://warehouse/wh/db_paimon.db/customer/c_nationkey=1/bucket-0/data-5d50255a-2215-4010-b976-
d5dc656f3444-0.orc start: 0 length: 44501 |
|      s3://warehouse/wh/db_paimon.db/customer/c_nationkey=2/bucket-0/data-e98fb7ef-ec2b-4ad5-a496-
713cb9481d56-0.orc start: 0 length: 64059 |
|      s3://warehouse/wh/db_paimon.db/customer/c_nationkey=0/bucket-0/data-431be05d-50fa-401f-9680-
d646757d0f95-0.orc start: 0 length: 63164 |
|      cardinality=18751, numNodes=1
|
|      pushdown agg=NONE
|
|      paimonNativeReadSplits=4/4
|
|      PaimonSplitStats:
|
|      SplitStat [type=NATIVE, rowCount=1542, rawFileConvertible=true, hasDeletionVector=true]
|
|      SplitStat [type=NATIVE, rowCount=750, rawFileConvertible=true, hasDeletionVector=false]
|
|      SplitStat [type=NATIVE, rowCount=750, rawFileConvertible=true, hasDeletionVector=false]
|
|      tuple ids: 0
|      .....
|
+-----+
-----+
67 rows in set (0.23 sec)

```

It can be seen that the table just updated by Flink SQL contains 4 shards, and all shards can be accessed through Native Reader (paimonNativeReadSplits=4/4). In addition, the hasDeletionVector property of the first shard is true, indicating that the shard has a corresponding Deletion Vector, and data will be filtered according to the Deletion Vector when reading.

Using Doris and Iceberg

As a new open data management architecture, the Data Lakehouse integrates the high performance and real-time capabilities of a data warehouse with the low cost and flexibility of a data lake, helping users more conveniently meet various data processing and analysis needs. It has been increasingly applied in enterprise big data systems.

In recent versions, Apache Doris has deepened its integration with data lakes and now offers a mature Data Lakehouse solution.

- Since version 0.15, Apache Doris has introduced Hive and Iceberg external tables, exploring the capabilities of combining with Apache Iceberg for data lakes.
- Starting from version 1.2, Apache Doris officially introduced the Multi-Catalog feature, enabling automatic metadata mapping and data access for various data sources, along with numerous performance optimizations for external data reading and query execution. It now fully supports building a high-speed and user-friendly Lakehouse architecture.
- In version 2.1, Apache Doris further strengthened its Data Lakehouse architecture, enhancing the reading and writing capabilities of mainstream data lake formats (Hudi, Iceberg, Paimon, etc.), introducing compatibility with multiple SQL dialects, and seamless migration from existing systems to Apache Doris. For data science and large-scale data reading scenarios, Doris integrated the Arrow Flight high-speed reading interface, achieving a 100x improvement in data transfer efficiency.

Building Lakehouse using Doris and Iceberg

Apache Doris & Iceberg

Apache Iceberg is an open-source, high-performance, and highly reliable data lake table format that enables the analysis and management of massive-scale data. It supports various mainstream query engines, including Apache Doris, is compatible with HDFS and various object cloud storage, and features ACID compliance,

schema evolution, advanced filtering, hidden partitioning, and partition layout evolution to ensure high-performance queries, data reliability, consistency, and flexibility with features like time travel and version rollback.

Apache Doris provides native support for several core features of Iceberg:

- Supports multiple Iceberg Catalog types such as Hive Metastore, Hadoop, REST, Glue, Google Dataproc Metastore, DLF, etc.
- Native support for Iceberg V1/V2 table formats and reading of Position Delete, Equality Delete files.
- Supports querying Iceberg table snapshot history through table functions.
- Supports Time Travel functionality.
- Native support for the Iceberg table engine. It allows Apache Doris to directly create, manage, and write data to Iceberg tables. It supports comprehensive partition Transform functions, providing capabilities like hidden partitioning and partition layout evolution.

Users can quickly build an efficient Data Lakehouse solution based on Apache Doris + Apache Iceberg to flexibly address various real-time data analysis and processing needs.

- Use the high-performance query engine of Doris to perform data analysis by associating Iceberg table data and other data sources, building a **unified federated data analysis platform**.
- Manage and build Iceberg tables directly through Doris, complete data cleaning, processing, and writing to Iceberg tables in Doris, building a **unified data processing platform for data lakes**.
- Share Doris data with other upstream and downstream systems for further processing through the Iceberg table engine, building a **unified open data storage platform**.

In the future, Apache Iceberg will serve as one of the native table engines for Apache Doris, providing more comprehensive analysis and management functions for lake-formatted data. Apache Doris will also gradually support more advanced features of Apache Iceberg, including Update/Delete/Merge, sorting during write-back, incremental data reading, metadata management, etc., to jointly build a unified, high-performance, real-time data lake platform.

For more information, please refer to [Iceberg Catalog](#).

User Guide

This document mainly explains how to quickly set up an Apache Doris + Apache Iceberg testing & demonstration environment in a Docker environment and demonstrate the usage of various functions.

All scripts and code mentioned in this document can be obtained from this address:

https://github.com/apache/doris/tree/master/samples/datalake/iceberg_and_paimon

01 Environment Preparation

This document uses Docker Compose for deployment, with the following components and versions:

| Component | Version |
|----------------|--------------------------------|
| Apache Doris | Default 2.1.5, can be modified |
| Apache Iceberg | 1.4.3 |

| Component | Version |
|-----------|------------------------------|
| MinIO | RELEASE.2024-04-29T09-56-05Z |

02 Environment Deployment

1. Start all components

```
bash ./start_all.sh
```

2. After starting, you can use the following script to log in to the Doris command line:

```
-- login doris
bash ./start_doris_client.sh
```

03 Create Iceberg Table

After logging into the Doris command line, an Iceberg Catalog named Iceberg has already been created in the Doris cluster (can be viewed by `SHOW CATALOGS/SHOW CREATE CATALOG iceberg`). The following is the creation statement for this Catalog:

```
-- Already created
CREATE CATALOG `iceberg` PROPERTIES (
  "type" = "iceberg",
  "iceberg.catalog.type" = "rest",
  "warehouse" = "s3://warehouse/",
  "uri" = "http://rest:8181",
  "s3.access_key" = "admin",
  "s3.secret_key" = "password",
  "s3.endpoint" = "http://minio:9000"
);
```

Create a database and an Iceberg table in the Iceberg Catalog:

```
mysql> SWITCH iceberg;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE DATABASE nyc;
Query OK, 0 rows affected (0.12 sec)

mysql> CREATE TABLE iceberg.nyc.taxis
(
  vendor_id BIGINT,
  trip_id BIGINT,
  trip_distance FLOAT,
  fare_amount DOUBLE,
  store_and_fwd_flag STRING,
  ts DATETIME
)
PARTITION BY LIST (vendor_id, DAY(ts)) ()
PROPERTIES (
  "compression-codec" = "zstd",
  "write-format" = "parquet"
);
Query OK, 0 rows affected (0.15 sec)
```

04 Data Insertion

Insert data into the Iceberg table:

```
mysql> INSERT INTO iceberg.nyc.taxis
VALUES
  (1, 1000371, 1.8, 15.32, 'N', '2024-01-01 9:15:23'),
  (2, 1000372, 2.5, 22.15, 'N', '2024-01-02 12:10:11'),
  (2, 1000373, 0.9, 9.01, 'N', '2024-01-01 3:25:15'),
  (1, 1000374, 8.4, 42.13, 'Y', '2024-01-03 7:12:33');
Query OK, 4 rows affected (1.61 sec)
{'status':'COMMITTED', 'txnId':'10085'}
```

Create an Iceberg table using CREATE TABLE AS SELECT:

```
mysql> CREATE TABLE iceberg.nyc.taxis2 AS SELECT * FROM iceberg.nyc.taxis;
Query OK, 4 rows affected (0.25 sec)
{'status':'COMMITTED', 'txnId':'10088'}
```

05 Data Query

- Simple query

```
mysql> SELECT * FROM iceberg.nyc.taxis;
+-----+-----+-----+-----+-----+-----+
+
| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts
|
+-----+-----+-----+-----+-----+-----+
+
|          1 | 1000374 |          8.4 |         42.13 | Y                   | 2024-01-03 07:12:33.000000
|
|          1 | 1000371 |          1.8 |         15.32 | N                   | 2024-01-01 09:15:23.000000
|
|          2 | 1000373 |          0.9 |          9.01 | N                   | 2024-01-01 03:25:15.000000
|
|          2 | 1000372 |          2.5 |         22.15 | N                   | 2024-01-02 12:10:11.000000
|
+-----+-----+-----+-----+-----+-----+
+
4 rows in set (0.37 sec)

mysql> SELECT * FROM iceberg.nyc.taxis2;
+-----+-----+-----+-----+-----+-----+
+
| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts
|
+-----+-----+-----+-----+-----+-----+
+
|          1 | 1000374 |          8.4 |         42.13 | Y                   | 2024-01-03 07:12:33.000000
|
|          1 | 1000371 |          1.8 |         15.32 | N                   | 2024-01-01 09:15:23.000000
|
|          2 | 1000373 |          0.9 |          9.01 | N                   | 2024-01-01 03:25:15.000000
|
|          2 | 1000372 |          2.5 |         22.15 | N                   | 2024-01-02 12:10:11.000000
|
+-----+-----+-----+-----+-----+-----+
```

```
+
4 rows in set (0.35 sec)
```

- Partition pruning

```
mysql> SELECT * FROM iceberg.nyc.taxis where vendor_id = 2 and ts >= '2024-01-01' and ts < '2024-01-02';
+-----+-----+-----+-----+-----+-----+
+
| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts
|
+-----+-----+-----+-----+-----+-----+
+
|          2 | 1000373 |          0.9 |          9.01 | N                    | 2024-01-01 03:25:15.000000
|
+-----+-----+-----+-----+-----+-----+
+
1 row in set (0.06 sec)

mysql> EXPLAIN VERBOSE SELECT * FROM iceberg.nyc.taxis where vendor_id = 2 and ts >= '2024-01-01' and
ts < '2024-01-02';

....
| 0:VICEBERG_SCAN_NODE(71)
|   table: taxis
|   predicates: (ts[#5] < '2024-01-02 00:00:00'), (vendor_id[#0] = 2), (ts[#5] >= '2024-01-01
00:00:00')
|   inputSplitNum=1, totalFileSize=3539, scanRanges=1
|   partition=1/0
|   backends:
|     10002
|     s3://warehouse/wh/nyc/taxis/data/vendor_id=2/ts_day=2024-01-01/40e6ca404efa4a44-
b888f23546d3a69c_5708e229-2f3d-4b68-a66b-44298a9d9815-0.zstd.parquet start: 0 length: 3539
|   cardinality=6, numNodes=1
|   pushdown agg=NONE
|   icebergPredicatePushdown=
|     ref(name="ts") < 1704153600000000
|     ref(name="vendor_id") == 2
|     ref(name="ts") >= 1704067200000000
|
....
```

By examining the result of the EXPLAIN VERBOSE statement, it can be seen that the predicate condition `vendor_id = 2 and ts >= '2024-01-01' and ts < '2024-01-02'` ultimately only hits one partition (`partition=1/0`).

It can also be observed that because a partition Transform function `DAY(ts)` was specified when creating the table, the original value in the data `2024-01-01 03:25:15.000000` will be transformed into the partition information in the file directory `ts_day=2024-01-01`.

06 Time Travel

Let's insert a few more rows of data:

```
INSERT INTO iceberg.nyc.taxis VALUES (1, 1000375, 8.8, 55.55, 'Y', '2024-01-01 8:10:22'), (3, 1000376, 7.4,
32.35, 'N', '2024-01-02 1:14:45');
Query OK, 2 rows affected (0.17 sec)
{'status':'COMMITTED', 'txnId':'10086'}
```

```
mysql> SELECT * FROM iceberg.nyc.taxis;
```

| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts |
|-----------|---------|---------------|-------------|--------------------|----------------------------|
| 3 | 1000376 | 7.4 | 32.35 | N | 2024-01-02 01:14:45.000000 |
| 2 | 1000372 | 2.5 | 22.15 | N | 2024-01-02 12:10:11.000000 |
| 1 | 1000374 | 8.4 | 42.13 | Y | 2024-01-03 07:12:33.000000 |
| 1 | 1000371 | 1.8 | 15.32 | N | 2024-01-01 09:15:23.000000 |
| 1 | 1000375 | 8.8 | 55.55 | Y | 2024-01-01 08:10:22.000000 |
| 2 | 1000373 | 0.9 | 9.01 | N | 2024-01-01 03:25:15.000000 |

```
6 rows in set (0.11 sec)
```

Use the iceberg_meta table function to query the snapshot information of the table:

```
mysql> select * from iceberg_meta("table" = "iceberg.nyc.taxis", "query_type" = "snapshots");
```

| committed_at | snapshot_id | parent_id | operation | manifest_list |
|---------------------|---------------------|---------------------|-----------|--|
| 2024-07-29 03:38:22 | 8483933166442433486 | -1 | append | s3://warehouse/wh/nyc/taxis/metadata/snap-8483933166442433486-1-5f7b7736-8022-4ba1-9db2-51ae7553be4d.avro {"added-data-files":"4","added-records":"4","added-files-size":"14156","changed-partition-count":"4","total-records":"4","total-files-size":"14156","total-data-files":"4","total-delete-files":"0","total-position-deletes":"0","total-equality-deletes":"0"} |
| 2024-07-29 03:40:23 | 4726331391239920914 | 8483933166442433486 | append | s3://warehouse/wh/nyc/taxis/metadata/snap-4726331391239920914-1-6aa3d142-6c9c-4553-9c04-08ad4d49a4ea.avro {"added-data-files":"2","added-records":"2","added-files-size":"7078","changed-partition-count":"2","total-records":"6","total-files-size":"21234","total-data-files":"6","total-delete-files":"0","total-position-deletes":"0","total-equality-deletes":"0"} |

```
2 rows in set (0.07 sec)
```

Query a specified snapshot using the FOR VERSION AS OF statement:

```
mysql> SELECT * FROM iceberg.nyc.taxis FOR VERSION AS OF 8483933166442433486;
```

| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts |
|-----------|---------|---------------|-------------|--------------------|----------------------------|
| 1 | 1000371 | 1.8 | 15.32 | N | 2024-01-01 09:15:23.000000 |
| 1 | 1000374 | 8.4 | 42.13 | Y | 2024-01-03 07:12:33.000000 |
| 2 | 1000372 | 2.5 | 22.15 | N | 2024-01-02 12:10:11.000000 |
| 2 | 1000373 | 0.9 | 9.01 | N | 2024-01-01 03:25:15.000000 |

```
4 rows in set (0.05 sec)
```

```
mysql> SELECT * FROM iceberg.nyc.taxis FOR VERSION AS OF 4726331391239920914;
```

| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts |
|-----------|---------|---------------|-------------|--------------------|----|
|-----------|---------|---------------|-------------|--------------------|----|

| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts |
|-----------|---------|---------------|-------------|--------------------|----------------------------|

07 Interacting with Pylceberg

Please use Doris 2.1.8/3.0.4 or above.

Load an iceberg table:

```
from pyiceberg.catalog import load_catalog

catalog = load_catalog(
    "iceberg",
    **{
        "warehouse" = "warehouse",
        "uri" = "http://rest:8181",
        "s3.access-key-id" = "admin",
        "s3.secret-access-key" = "password",
        "s3.endpoint" = "http://minio:9000"
    },
)

table = catalog.load_table("nyc.taxis")
```

Read table as Arrow Table:

```
print(table.scan().to_arrow())

pyarrow.Table
vendor_id: int64
trip_id: int64
trip_distance: float
fare_amount: double
store_and_fwd_flag: large_string
ts: timestamp[us]
----
vendor_id: [[1],[1],[2],[2]]
trip_id: [[1000371],[1000374],[1000373],[1000372]]
trip_distance: [[1.8],[8.4],[0.9],[2.5]]
fare_amount: [[15.32],[42.13],[9.01],[22.15]]
store_and_fwd_flag: [["N"],["Y"],["N"],["N"]]
ts: [[2024-01-01 09:15:23.000000],[2024-01-03 07:12:33.000000],[2024-01-01 03:25:15.000000],[2024-01-02 12:10:11.000000]]
```

Read table as Pandas DataFrame:

```
print(table.scan().to_pandas())

vendor_id  trip_id  trip_distance  fare_amount  store_and_fwd_flag  ts
0          1  1000371           1.8         15.32                N  2024-01-01 09:15:23
1          1  1000374           8.4         42.13                Y  2024-01-03 07:12:33
2          2  1000373           0.9          9.01                N  2024-01-01 03:25:15
3          2  1000372           2.5         22.15                N  2024-01-02 12:10:11
```

Read table as Polars DataFrame:

```
import polars as pl

print(pl.scan_iceberg(table).collect())

shape: (4, 6)
```

| vendor_id | trip_id | trip_distance | fare_amount | store_and_fwd_flag | ts |
|-----------|---------|---------------|-------------|--------------------|---------------------|
| --- | --- | --- | --- | --- | --- |
| i64 | i64 | f32 | f64 | str | datetime[μs] |
| 1 | 1000371 | 1.8 | 15.32 | N | 2024-01-01 09:15:23 |
| 1 | 1000374 | 8.4 | 42.13 | Y | 2024-01-03 07:12:33 |
| 2 | 1000373 | 0.9 | 9.01 | N | 2024-01-01 03:25:15 |
| 2 | 1000372 | 2.5 | 22.15 | N | 2024-01-02 12:10:11 |

Write iceberg table by Pylceberg, please see [step](#)

08 Appendix

Write iceberg table by Pylceberg

Load an iceberg table:

```

from pyiceberg.catalog import load_catalog

catalog = load_catalog(
    "iceberg",
    **{
        "warehouse" = "warehouse",
        "uri" = "http://rest:8181",
        "s3.access-key-id" = "admin",
        "s3.secret-access-key" = "password",
        "s3.endpoint" = "http://minio:9000"
    },
)
table = catalog.load_table("nyc.taxis")

```

Write table with Arrow Table :

```

import pyarrow as pa

df = pa.Table.from_pydict(
    {
        "vendor_id": pa.array([1, 2, 2, 1], pa.int64()),
        "trip_id": pa.array([1000371, 1000372, 1000373, 1000374], pa.int64()),
        "trip_distance": pa.array([1.8, 2.5, 0.9, 8.4], pa.float32()),
        "fare_amount": pa.array([15.32, 22.15, 9.01, 42.13], pa.float64()),
        "store_and_fwd_flag": pa.array(["N", "N", "N", "Y"], pa.string()),
        "ts": pa.compute.strptime(
            ["2024-01-01 9:15:23", "2024-01-02 12:10:11", "2024-01-01 3:25:15", "2024-01-03 7:12:33"],
            "%Y-%m-%d %H:%M:%S",
            "us",
        ),
    }
)
table.append(df)

```

Write table with Pandas DataFrame :

```

import pyarrow as pa
import pandas as pd

df = pd.DataFrame(
    {
        "vendor_id": pd.Series([1, 2, 2, 1]).astype("int64[pyarrow]"),
        "trip_id": pd.Series([1000371, 1000372, 1000373, 1000374]).astype("int64[pyarrow]"),
        "trip_distance": pd.Series([1.8, 2.5, 0.9, 8.4]).astype("float32[pyarrow]"),
        "fare_amount": pd.Series([15.32, 22.15, 9.01, 42.13]).astype("float64[pyarrow]"),
        "store_and_fwd_flag": pd.Series(["N", "N", "N", "Y"]).astype("string[pyarrow]"),
        "ts": pd.Series(["2024-01-01 9:15:23", "2024-01-02 12:10:11", "2024-01-01 3:25:15", "2024-01-03 7:12:33"]).astype("timestamp[us][pyarrow]"),
    }
)
table.append(pa.Table.from_pandas(df))

```

Write table with Polars DataFrame :

```

import polars as pl

df = pl.DataFrame(
    {
        "vendor_id": [1, 2, 2, 1],

```

```

        "trip_id": [1000371, 1000372, 1000373, 1000374],
        "trip_distance": [1.8, 2.5, 0.9, 8.4],
        "fare_amount": [15.32, 22.15, 9.01, 42.13],
        "store_and_fwd_flag": ["N", "N", "N", "Y"],
        "ts": ["2024-01-01 9:15:23", "2024-01-02 12:10:11", "2024-01-01 3:25:15", "2024-01-03 7:12:33"],
    },
    {
        "vendor_id": pl.Int64,
        "trip_id": pl.Int64,
        "trip_distance": pl.Float32,
        "fare_amount": pl.Float64,
        "store_and_fwd_flag": pl.String,
        "ts": pl.String,
    },
).with_columns(pl.col("ts").str.strptime(pl.Datetime, "%Y-%m-%d %H:%M:%S"))
table.append(df.to_arrow())

```

Using Doris and LakeSoul

As a new open data management architecture, the Data Lakehouse integrates the high performance and real-time capabilities of data warehouses with the low cost and flexibility of data lakes, helping users more conveniently meet various data processing and analysis needs. It has been increasingly applied in enterprise big data systems.

In recent versions, Apache Doris has deepened its integration with data lakes and has evolved a mature Data Lakehouse solution.

- Since version 0.15, Apache Doris has introduced Hive and Iceberg external tables, exploring the capabilities of combining with Apache Iceberg for data lakes.
- Starting from version 1.2, Apache Doris officially introduced the Multi-Catalog feature, enabling automatic metadata mapping and data access for various data sources, along with numerous performance optimizations for external data reading and query execution. It now fully possesses the ability to build a high-speed and user-friendly Lakehouse architecture.
- In version 2.1, Apache Doris' Data Lakehouse architecture was significantly enhanced, improving the reading and writing capabilities of mainstream data lake formats (Hudi, Iceberg, Paimon, etc.), introducing compatibility with multiple SQL dialects, and seamless migration from existing systems to Apache Doris. For data science and large-scale data reading scenarios, Doris integrated the Arrow Flight high-speed reading interface, achieving a 100-fold increase in data transfer efficiency.

Building lakehouse using doris and lakesoul

Apache Doris & LakeSoul

LakeSoul is a cloud-native lakehouse framework developed by DMetaSoul and donated to the Linux Foundation AI & Data Foundation in May 2023. It features high scalability in metadata management, ACID

transactions, efficient and flexible upsert operations, schema evolution, and batch-stream integrated processing .

With Apache Doris’ high-performance query engine and LakeSoul’s efficient data management, users can achieve:

- Real-time data ingestion into the lake: Leveraging LakeSoul’s architecture, data can be ingested into the lake with high efficiency and low latency, supporting various data update capabilities including aggregation, deduplication, and partial column updates.
- High-performance data processing and analysis: LakeSoul’s capabilities such as batch-stream integrated processing and schema evolution can be seamlessly integrated with Doris’ powerful query engine, enabling fast querying and analysis responses for lake data.

In the future, Apache Doris will gradually support more advanced features of LakeSoul, such as CDC stream synchronization and automatic schema evolution, to jointly build a unified, high-performance, real-time lakehouse platform.

This article will explain how to quickly set up an Apache Doris + LakeSoul testing & demonstration environment and demonstrate the usage of various features, showcasing the integration and benefits of using both systems in a lakehouse architecture .

For more information, please refer to [LakeSoul Catalog](#)

User Guide

All scripts and code mentioned in this article can be obtained from this address:

<https://github.com/apache/doris/tree/master/samples/datalake/lakesoul>

01 Environment Preparation

This article uses Docker Compose for deployment, with the following components and versions:

| Component | Version |
|--------------|------------------------------|
| Apache Doris | Default 3.0.2 |
| LakeSoul | 2.6.1 |
| Postgres | 14.5 |
| Apache Spark | 3.3.1 |
| Apache Flink | 1.17 |
| MinIO | RELEASE.2024-04-29T09-56-05Z |

02 Environment Deployment

1. Start all components

```
bash ./start_all.sh
```

2. After starting, you can use the following script to log in to the Doris command line:

```
-- login doris
bash ./start_doris_client.sh
```

03 Data Query

As shown below, a Catalog named lakesoul has been created in the Doris cluster (can be viewed using SHOW CATALOGS). The following is the creation statement for this Catalog:

```
-- Already created
CREATE CATALOG `lakesoul` PROPERTIES (
  'type'='lakesoul',
  'lakesoul.pg.username'='lakesoul_test',
  'lakesoul.pg.password'='lakesoul_test',
  'lakesoul.pg.url'='jdbc:postgresql://lakesoul-meta-pg:5432/lakesoul_test?stringtype=unspecified',
  'minio.endpoint'='http://minio:9000',
  'minio.access_key'='admin',
  'minio.secret_key'='password'
);
```

The LakeSoul Table lakesoul.tpch.customer has already been loaded into Doris. Query the data in Doris. - Simple query ``sql Doris> uselakesoul.tpch`; Database changed

```
Doris> show tables; +-----+ | Tables_in_tpch | +-----+ | customer_from_spark | +
-----+ 1 row in set (0.00 sec)
```

```
Doris> select * from customer_from_spark where c_nationkey = 1 order by c_custkey limit 4; +-----+

isAutoIncrement=false, subColPath=null}
|   SlotDescriptor{id=6, col=c_mktsegment, colUniqueId=6, type=text, nullable=true,

```

```

isAutoIncrement=false, subColPath=null}
| SlotDescriptor{id=7, col=c_comment, colUniqueId=7, type=text, nullable=true,
isAutoIncrement=false, subColPath=null}
+-----+
57 rows in set (0.03 sec)

```

By examining the result of the EXPLAIN VERBOSE statement, it can be seen that the predicate condition `c_nationkey < 3` ultimately only hits one partition (partition=0/0).

04 CDC Table Support

Launch Flink CDC Job to sync mysql table. The mysql table is loaded when launching docker compose.

```
bash start_flink_cdc_job.sh
```

```

Start flink-cdc job...
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding in [jar:file:/opt/flink/lib/log4j-slf4j-impl-
2.17.1.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/opt/hadoop/share/hadoop/common/lib/slf4j-reload4j-
1.7.36.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an explanation.
SLF4J: Actual binding is of type [org.apache.logging.slf4j.Log4jLoggerFactory]
Loading class `com.mysql.jdbc.Driver'. This is deprecated. The new driver class is
`com.mysql.cj.jdbc.Driver'. The driver is automatically registered via the SPI and manual loading of the
driver class is generally unnecessary.
Job has been submitted with JobID d1b3641dcd1ad85c6b373d49b1867e68

```

Flink CDC Job will be launched. We can check the process of launching at `doris client` by recreate the lakesoul catalog. After the Flink CDC Job has been launched, we can see the syncing LakeSoul CDC table at `doris client`.

```

Doris> show tables;

Integration with Glue + AWS S3 Tables

[AWS S3 Tables](#) is a special type of S3 Bucket that provides read and write interfaces compatible with Apache Iceberg table format standards, built on Amazon S3, offering the same durability, availability, scalability, and performance characteristics as S3 itself. Additionally, S3 Tables provides the following features:

- Compared to Iceberg tables stored in regular S3 Buckets, S3 Tables can deliver up to 3x higher query performance and up to 10x higher transactions per second.
- Automated table management. S3 Tables automatically optimizes Iceberg table data, including small file compaction, snapshot management, and garbage file cleanup.

The release of S3 Tables further simplifies Lakehouse architecture and brings more possibilities for cloud-native lake-warehouse systems. This includes cold-hot separation, data archiving, data backup, and compute-storage separation architectures, all of which could evolve into entirely new architectures based on S3 Tables.

Thanks to Amazon S3 Tables' high compatibility with the Iceberg API, Apache Doris can quickly integrate with S3 Tables. This article will demonstrate how to connect Apache Doris with S3 Tables and perform data analysis and processing.

This feature is supported since Doris 3.1

Usage Guide

01 Create S3 Table Bucket

S3 Table Bucket is the third type of Bucket launched by S3, on par with the previous General purpose bucket and Directory bucket.

Amazon S3

General purpose buckets

Directory buckets

Table buckets

Access Grants

Access Points

Object Lambda Access Points

Multi-Region Access Points

Batch Operations

IAM Access Analyzer for S3

AWS S3 Table Bucket

Here we create a Table Bucket named doris-s3-table-bucket. After creation, we will get a Table Bucket represented by an ARN.

| Table buckets (3) | | | | | Create table bucket |
|--|---------------------------------|------------------------------|--|---------|---------------------|
| <input type="text" value="Find table buckets by start of name"/> | | | | < 1 > ⚙ | |
| Name | Amazon Resource Name (ARN) | | Creation date | | |
| doris-s3-table-bucket | arn:aws:s3tables:us-east-1:1696 | bucket/doris-s3-table-bucket | January 15, 2025, 22:58:00 (UTC+08:00) | | |

AWS S3 Table Bucket Create

02 Create Iceberg Catalog

- Create an Iceberg Catalog of type s3tables

```
CREATE CATALOG iceberg_s3 PROPERTIES (  
  'type' = 'iceberg',  
  'iceberg.catalog.type' = 's3tables',  
  'warehouse' = 'arn:aws:s3tables:<region>:<account_id>:bucket/<s3_table_bucket_name>',  
  's3.region' = '<region>',
```

```
's3.endpoint' = 's3.<region>.amazonaws.com',
's3.access_key' = '<ak>',
's3.secret_key' = '<sk>'
);
```

- Connecting to s3 tables using Glue Rest Catalog

```
CREATE CATALOG glue_s3 PROPERTIES (
  'type' = 'iceberg',
  'iceberg.catalog.type' = 'rest',
  'iceberg.rest.uri' = 'https://glue.<region>.amazonaws.com/iceberg',
  'warehouse' = '<account_id>:s3tablescatalog/<s3_table_bucket_name>',
  'iceberg.rest.sigv4-enabled' = 'true',
  'iceberg.rest.signing-name' = 'glue',
  'iceberg.rest.access-key-id' = '<ak>',
  'iceberg.rest.secret-access-key' = '<sk>',
  'iceberg.rest.signing-region' = '<region>'
);
```

03 Access S3Tables

```
Doris > SWITCH aws_s3_tables;
```

```
Doris > SHOW DATABASES;
```

```
+-----+
| Database |
+-----+
| information_schema |
| my_namespace |
| mysql |
+-----+
```

```
Doris > USE my_namespace;
```

```
Doris > SHOW TABLES;
```

```
+-----+
| Tables_in_my_namespace |
+-----+
| my_table |
+-----+
```

```
Doris > SELECT * FROM my_table;
```

```
+-----+-----+-----+
| id | name | value |
+-----+-----+-----+
| 1 | ABC | 100 |
| 2 | XYZ | 200 |
+-----+-----+-----+
```

04 Create S3Tables Table and Write Data

```
Doris > CREATE TABLE partition_table (
  -> `ts` DATETIME COMMENT 'ts',
  -> `id` INT COMMENT 'col1',
  -> `pt1` STRING COMMENT 'pt1',
  -> `pt2` STRING COMMENT 'pt2'
  -> )
  -> PARTITION BY LIST (day(ts), pt1, pt2) ();
```

```
Doris > INSERT INTO partition_table VALUES
  -> ("2024-01-01 08:00:00", 1000, "us-east", "PART1"),
  -> ("2024-01-02 10:00:00", 1002, "us-sout", "PART2");
Query OK, 2 rows affected
{'status': 'COMMITTED', 'txnId': '1736935786473'}
```

```
Doris > SELECT * FROM partition_table;
```

| ts | id | pt1 | pt2 |
|----------------------------|------|---------|-------|
| 2024-01-02 10:00:00.000000 | 1002 | us-sout | PART2 |
| 2024-01-01 08:00:00.000000 | 1000 | us-east | PART1 |

05 Time Travel

We can insert another batch of data, then use the \$snapshots system table to view Iceberg Snapshots:

```
Doris > INSERT INTO partition_table VALUES
  -> ("2024-01-03 08:00:00", 1000, "us-east", "PART1"),
  -> ("2024-01-04 10:00:00", 1002, "us-sout", "PART2");
Query OK, 2 rows affected (9.76 sec)
{'status': 'COMMITTED', 'txnId': '1736935786474'}
```

```
Doris > SELECT * FROM partition_table$snapshots\G
***** 1. row *****
committed_at: 2025-01-15 23:27:01
snapshot_id: 6834769222601914216
parent_id: -1
operation: append
manifest_list: s3://80afcb3f-6edf-46f2-7fhehwj6cengfwc7n6iz7ipzakd7quse1b--table-s3/metadata/snap-6834769222601914216-1-a6b2230d-fc0d-4c1d-8f20-94bb798f27b1.avro
summary: {"added-data-files":"2","added-records":"2","added-files-size":"5152","changed-partition-count":"2","total-records":"2","total-files-size":"5152","total-data-files":"2","total-delete-files":"0","total-position-deletes":"0","total-equality-deletes":"0","iceberg-version":"Apache Iceberg 1.6.1 (commit 8e9d59d299be42b0bca9461457cd1e95dbaad086)"}
***** 2. row *****
committed_at: 2025-01-15 23:30:00
snapshot_id: 5670090782912867298
parent_id: 6834769222601914216
operation: append
manifest_list: s3://80afcb3f-6edf-46f2-7fhehwj6cengfwc7n6iz7ipzakd7quse1b--table-s3/metadata/snap-5670090782912867298-1-beeed339-be96-4710-858b-f39bb01cc3ff.avro
summary: {"added-data-files":"2","added-records":"2","added-files-size":"5152","changed-partition-count":"2","total-records":"4","total-files-size":"10304","total-data-files":"4","total-delete-files":"0","total-position-deletes":"0","total-equality-deletes":"0","iceberg-version":"Apache Iceberg 1.6.1 (commit 8e9d59d299be42b0bca9461457cd1e95dbaad086)"}
*****
```

Use the VERSION AS OF syntax to query different snapshots:

```
Doris > SELECT * FROM partition_table FOR VERSION AS OF 5670090782912867298;
```

| ts | id | pt1 | pt2 |
|----------------------------|------|---------|-------|
| 2024-01-04 10:00:00.000000 | 1002 | us-sout | PART2 |
| 2024-01-03 08:00:00.000000 | 1000 | us-east | PART1 |
| 2024-01-01 08:00:00.000000 | 1000 | us-east | PART1 |
| 2024-01-02 10:00:00.000000 | 1002 | us-sout | PART2 |

```

+-----+-----+-----+-----+
Doris > SELECT * FROM partition_table FOR VERSION AS OF 6834769222601914216;
+-----+-----+-----+-----+
| ts                | id  | pt1  | pt2  |
+-----+-----+-----+-----+
| 2024-01-02 10:00:00.000000 | 1002 | us-sout | PART2 |
| 2024-01-01 08:00:00.000000 | 1000 | us-east | PART1 |
+-----+-----+-----+-----+

```

06 Access S3 Tables Using EMR Spark

Data written using Doris can also be accessed using Spark:

```

spark-shell --jars /usr/share/aws/iceberg/lib//iceberg-spark-runtime-3.5_2.12-1.6.1-amzn-1.jar \
--packages software.amazon.s3tables:s3-tables-catalog-for-iceberg-runtime:0.1.3 \
--conf spark.sql.catalog.s3tablesbucket=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.s3tablesbucket.catalog-impl=software.amazon.s3tables.iceberg.S3TablesCatalog \
--conf spark.sql.catalog.s3tablesbucket.warehouse=arn:aws:s3tables:us-east-1:169698000000:bucket/doris-s3-
table-bucket \
--conf spark.sql.defaultCatalog=s3tablesbucket \
--conf spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions

```

```

scala> spark.sql("SELECT * FROM s3tablesbucket.my_namespace.`partition_table` ").show()
+-----+-----+-----+-----+
|          ts| id|   pt1| pt2|
+-----+-----+-----+-----+
2024-01-02 10:00:00	1002	us-sout	PART2
2024-01-01 08:00:00	1000	us-east	PART1
2024-01-04 10:00:00	1002	us-sout	PART2
2024-01-03 08:00:00	1000	us-east	PART1
+-----+-----+-----+-----+

```

Integration with Aliyun DLF Rest Catalog

Aliyun [Data Lake Formation \(DLF\)](#) serves as a core component of cloud-native data lake architecture, helping users quickly build cloud-native data lake architectures. Data Lake Formation provides unified metadata management on the lake, enterprise-level permission control, and seamlessly integrates with multiple computing engines to break data silos and uncover business value.

- Unified Metadata and Storage

Computing engines share a unified set of lake metadata and storage, enabling data flow between lake ecosystem products.

- Unified Permission Management

Computing engines share a unified set of lake table permission configurations, achieving one-time configuration with multi-location effectiveness.

- Storage Optimization

Provides optimization strategies including small file merging, expired snapshot cleanup, partition organization, and obsolete file cleanup to improve storage efficiency.

- Comprehensive Cloud Ecosystem Support

Deep integration with Alibaba Cloud products, including streaming and batch computing engines, enabling out-of-the-box functionality and enhancing user experience and operational convenience.

Starting from DLF version 2.5, Paimon Rest Catalog is supported. Doris, beginning from version 3.1.0, supports integration with DLF 2.5+ Paimon Rest Catalog, enabling seamless connection to DLF for accessing and analyzing Paimon table data. This document demonstrates how to use Apache Doris to connect to DLF 2.5+ and access Paimon table data.

This feature is supported since Doris 3.1

Usage Guide

01 Enable DLF Service

Please refer to the DLF official documentation to enable the DLF service and create corresponding Catalog, Database, and Table.

02 Access DLF Using EMR Spark SQL

- Connection

```
spark-sql --master yarn \
  --conf spark.driver.memory=5g \
  --conf spark.sql.defaultCatalog=paimon \
  --conf spark.sql.catalog.paimon=org.apache.paimon.spark.SparkCatalog \
  --conf spark.sql.catalog.paimon.metastore=rest \
  --conf spark.sql.extensions=org.apache.paimon.spark.extensions.PaimonSparkSessionExtensions \
  --conf spark.sql.catalog.paimon.uri=http://<region>-vpc.dlf.aliyuncs.com \
  --conf spark.sql.catalog.paimon.warehouse=<your-catalog-name> \
  --conf spark.sql.catalog.paimon.token.provider=dlf \
  --conf spark.sql.catalog.paimon.dlf.token-loader=ecs
```

Replace the corresponding warehouse and uri address.

- Write Data

```
USE <your-catalog-name>;

CREATE TABLE users_samples
(
  user_id INT,
  age_level STRING,
  final_gender_code STRING,
  clk BOOLEAN
);

INSERT INTO users_samples VALUES
(1, '25-34', 'M', true),
(2, '18-24', 'F', false);

INSERT INTO users_samples VALUES
(3, '25-34', 'M', true),
(4, '18-24', 'F', false);

INSERT INTO users_samples VALUES
(5, '25-34', 'M', true),
(6, '18-24', 'F', false);
```

If you encounter the following error, please try removing paimon-jindo-x.y.z.jar from /opt/apps/PAIMON/paimon-dlf-2.5/lib/spark3 and restart the Spark service before retrying.

```
Ambiguous FileIO classes are:
org.apache.paimon.jindo.JindoLoader
org.apache.paimon.oss.OSSLoader
```

03 Connect Doris to DLF

- Create Paimon Catalog

```
CREATE CATALOG paimon_dlf_test PROPERTIES (
  'type' = 'paimon',
  'paimon.catalog.type' = 'rest',
  'uri' = 'http://<region>-vpc.dlf.aliyuncs.com',
  'warehouse' = '<your-catalog-name>',
  'paimon.rest.token.provider' = 'dlf',
```

```
'paimon.rest.dlf.access-key-id' = '<ak>',
'paimon.rest.dlf.access-key-secret' = '<sk>'
);
```

- Doris will use temporary credentials returned by DLF to access OSS object storage, without requiring additional OSS credential information.
- Only supports accessing DLF within the same VPC, ensure you provide the correct uri address.

• Query Data

```
SELECT * FROM users_samples ORDER BY user_id;
```

| user_id | age_level | final_gender_code | clk |
|---------|-----------|-------------------|-----|
| 1 | 25-34 | M | 1 |
| 2 | 18-24 | F | 0 |
| 3 | 25-34 | M | 1 |
| 4 | 18-24 | F | 0 |
| 5 | 25-34 | M | 1 |
| 6 | 18-24 | F | 0 |

• Query System Tables

```
SELECT snapshot_id, commit_time, total_record_count FROM users_samples$snapshots;
```

| snapshot_id | commit_time | total_record_count |
|-------------|-------------------------|--------------------|
| 1 | 2025-08-09 05:56:02.906 | 2 |

From MaxCompute to Doris

This document explains how to quickly import data from Alibaba Cloud MaxCompute into Apache Doris using the [MaxCompute Catalog](#).

This document is based on Apache Doris version 2.1.9.

Environment Preparation

01 Enable MaxCompute Open Storage API

In the left navigation bar of the [MaxCompute Console](#) -> Tenant Management -> Tenant Properties -> Turn on the Open Storage (Storage API) switch.

02 Enable MaxCompute Permissions

Doris uses AK/SK to access MaxCompute services. Please ensure that the IAM user corresponding to the AK/SK has the following roles or permissions for the corresponding MaxCompute services:

```
{
  "Statement": [{
    "Action": ["odps:List",
              "odps:Usage"],
    "Effect": "Allow",
    "Resource": ["acs:odps:*:regions/*/quotas/pay-as-you-go"]}],
  "Version": "1"
}
```

03 Confirm Doris and MaxCompute Network Environment

It is strongly recommended that the Doris cluster and MaxCompute service are in the same VPC and ensure that the correct security group is set.

The examples in this document are tested in the same VPC network environment.

Import MaxCompute Data

01 Create Catalog

```
CREATE CATALOG mc PROPERTIES (
  "type" = "max_compute",
  "mc.default.project" = "xxx",
  "mc.access_key" = "AKxxxxx",
  "mc.secret_key" = "SKxxxxx",
  "mc.endpoint" = "xxxxx"
);
```

Support Schema Level (3.1.3+):

```
CREATE CATALOG mc PROPERTIES (
  "type" = "max_compute",
  "mc.default.project" = "xxx",
  "mc.access_key" = "AKxxxxx",
  "mc.secret_key" = "SKxxxxx",
  "mc.endpoint" = "xxxxx",
  'mc.enable.namespace.schema' = 'true'
);
```

Please refer to the [MaxCompute Catalog](#) documentation for details.

02 Import TPCB Dataset

We use the TPCB 100 dataset from the public datasets in MaxCompute as an example (data has already been imported into MaxCompute), and use the `CREATE TABLE AS SELECT` statement to import MaxCompute data into Doris.

This dataset contains 7 tables. The largest table, `lineitem`, has 16 columns and 600,037,902 rows. It occupies about 30GB of disk space.

```
-- switch catalog
SWITCH internal;
-- create database
CREATE DATABASE tpch_100g;
-- ingest data
CREATE TABLE tpch_100g.lineitem AS SELECT * FROM mc.selectdb_test.lineitem;
CREATE TABLE tpch_100g.nation AS SELECT * FROM mc.selectdb_test.nation;
CREATE TABLE tpch_100g.orders AS SELECT * FROM mc.selectdb_test.orders;
CREATE TABLE tpch_100g.part AS SELECT * FROM mc.selectdb_test.part;
CREATE TABLE tpch_100g.partsupp AS SELECT * FROM mc.selectdb_test.partsupp;
CREATE TABLE tpch_100g.region AS SELECT * FROM mc.selectdb_test.region;
CREATE TABLE tpch_100g.supplier AS SELECT * FROM mc.selectdb_test.supplier;
```

In a Doris cluster with a single BE of 16C 64G specification, the above operations take about 6-7 minutes to execute serially.

03 Import Github Event Dataset

We use the Github Event dataset from the public datasets in MaxCompute as an example (data has already been imported into MaxCompute), and use the `CREATE TABLE AS SELECT` statement to import MaxCompute data into Doris.

Here we select data from the `dwd_github_events_odps` table for the 365 partitions from '2015-01-01' to '2016-01-01'. The data has 32 columns and 212,786,803 rows. It occupies about 10GB of disk space.

```
-- switch catalog
SWITCH internal;
-- create database
CREATE DATABASE github_events;
-- ingest data
CREATE TABLE github_events.dwd_github_events_odps
AS SELECT * FROM mc.github_events.dwd_github_events_odps
WHERE ds BETWEEN '2015-01-01' AND '2016-01-01';
```

In a Doris cluster with a single BE of 16C 64G specification, the above operation takes about 2 minutes.

Generating TPC-H on Hive/Iceberg

Doris supports using the [Trino Connector](#) compatible framework to quickly build TPC-H test sets with the [TPCH Connector](#).

By combining the data write-back function of Hive/Iceberg tables, you can quickly build TPC-H test datasets for Doris, Hive, and Iceberg tables through Doris.

This document mainly introduces how to deploy and use the TPC-H Connector to build test datasets.

This feature is supported starting from Doris version 3.0.0.

Compile TPC-H Connector

Requires JDK version 17.

```
git clone https://github.com/trinodb/trino.git
git checkout 435
cd trino/plugin/trino-tpch
mvn clean install -DskipTests
```

After compilation, you will get the `trino-tpch-435/` directory under `trino/plugin/trino-tpch/target/`.

You can also directly download the precompiled [trino-tpch-435.tar.gz](#) and extract it.

Deploy TPC-H Connector

Place the `trino-tpch-435/` directory into the `connectors/` directory of all FE and BE deployment paths. (If not present, you can create it manually).

```
| bin
| conf
| connectors
|   | trino-tpch-435
|   ...
```

After deployment, it is recommended to restart the FE and BE nodes to ensure the Connector can be loaded correctly.

Create TPC-H Catalog

```
CREATE CATALOG `tpch` PROPERTIES (
  "type" = "trino-connector",
  "trino.connector.name" = "tpch",
```

```

    "trino.tpch.column-naming" = "STANDARD",
    "trino.tpch.splits-per-node" = "32"
);

```

The `tpch.splits-per-node` is the concurrency number, which is recommended to be set to 2 times the number of cores per BE machine to achieve optimal concurrency. This improves data generation efficiency.

When `"tpch.column-naming" = "STANDARD"`, the column names in the TPCB table will start with the table name abbreviation, such as `l_orderkey`, otherwise, it is `orderkey`.

Use TPCB Catalog

The TPCB Catalog has pre-configured TPCB datasets of different Scale Factors, which can be viewed using the `SHOW DATABASES` and `SHOW TABLES` commands.

```

mysql> SWITCH tpch;
Query OK, 0 rows affected (0.00 sec)

```

```

mysql> SHOW DATABASES;

```

| Database |
|--------------------|
| information_schema |
| mysql |
| sf1 |
| sf100 |
| sf1000 |
| sf10000 |
| sf100000 |
| sf300 |
| sf3000 |
| sf30000 |
| tiny |

```

mysql> USE sf1;
mysql> SHOW TABLES;

```

| Tables_in_sf1 |
|---------------|
| customer |
| lineitem |
| nation |
| orders |
| part |
| partsupp |
| region |
| supplier |

You can directly query these tables using the `SELECT` statement.

The data in these pre-configured datasets is not actually stored but is generated in real-time during queries. Therefore, these pre-configured datasets are not suitable for direct Benchmark testing. They are suitable for writing datasets into other target tables (such as Doris internal

tables, Hive, Iceberg, and all other data sources that Doris supports writing to) through INSERT INTO SELECT, and then performing performance testing on the target tables.

Build TPCB Test Dataset

The following example quickly builds a TPCB test dataset on Hive using the CTAS statement:

```
CREATE TABLE hive.tpch100.customer PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.customer
;
CREATE TABLE hive.tpch100.lineitem PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.lineitem
;
CREATE TABLE hive.tpch100.nation PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.nation
;
CREATE TABLE hive.tpch100.orders PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.orders
;
CREATE TABLE hive.tpch100.part PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.part
;
CREATE TABLE hive.tpch100.partsupp PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.partsupp
;
CREATE TABLE hive.tpch100.region PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.region
;
CREATE TABLE hive.tpch100.supplier PROPERTIES("file_format" = "parquet") AS SELECT * FROM tpch.sf100.supplier
;
```

In a Doris cluster with 3 16C BE nodes, creating a TPCB 1000 Hive dataset takes about 25 minutes, and TPCB 10000 takes about 4 to 5 hours.

Generating TPC-DS on Hive/Iceberg

Doris supports using the [TPCDS Connector](#) to quickly build TPCDS test sets through the [Trino Connector](#) compatible framework.

Combined with the data write-back function of Hive/Iceberg tables, you can quickly build TPCDS test data sets for Doris, Hive, and Iceberg tables through Doris.

This document mainly introduces how to deploy and use the TPCDS Connector to build test data sets.

This feature is supported starting from Doris version 3.0.0.

Compile TPCDS Connector

Requires JDK version 17.

```
git clone https://github.com/trinodb/trino.git
git checkout 435
cd trino/plugin/trino-tpcds
mvn clean install -DskipTests
```

After compilation, you will get the `trino-tpcds-435/` directory under `trino/plugin/trino-tpcds/target/`.

You can also directly download the precompiled [trino-tpcds-435.tar.gz](#) and extract it.

Deploy TPCDS Connector

Place the `trino-tpcds-435/` directory under the `connectors/` directory of all FE and BE deployment paths. (If not present, you can create it manually).

```
|— bin
|— conf
|— connectors
|   |— trino-tpcds-435
...

```

After deployment, it is recommended to restart the FE and BE nodes to ensure the Connector can be loaded correctly.

Create TPCDS Catalog

```
CREATE CATALOG `tpcds` PROPERTIES (
  "type" = "trino-connector",
  "trino.connector.name" = "tpcds",
```

```
"trino.tpcds.split-count" = "32"
);
```

The `tpcds.split-count` is the concurrency number, which is recommended to be set to 2 times the number of cores per BE machine to achieve optimal concurrency. Improve data generation efficiency.

Use TPCDS Catalog

The TPCDS Catalog has pre-built TPCDS datasets of different Scale Factors, which can be viewed using the `SHOW DATABASES` and `SHOW TABLES` commands.

```
mysql> SWITCH tpcds;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW DATABASES;
```

| Database |
|--------------------|
| information_schema |
| mysql |
| sf1 |
| sf100 |
| sf1000 |
| sf10000 |
| sf100000 |
| sf300 |
| sf3000 |
| sf30000 |
| tiny |

```
mysql> USE sf1;
```

```
mysql> SHOW TABLES;
```

| Tables_in_sf1 |
|------------------------|
| call_center |
| catalog_page |
| catalog_returns |
| catalog_sales |
| customer |
| customer_address |
| customer_demographics |
| date_dim |
| dbgen_version |
| household_demographics |
| income_band |
| inventory |
| item |
| promotion |
| reason |
| ship_mode |
| store |
| store_returns |
| store_sales |
| time_dim |
| warehouse |
| web_page |
| web_returns |
| web_sales |

```
| web_site |
+-----+
```

You can directly query these tables using the SELECT statement.

The data of these pre-built datasets is not actually stored but is generated in real-time during queries. Therefore, these pre-built datasets are not suitable for direct Benchmark testing. They are suitable for writing datasets into other target tables (such as Doris internal tables, Hive, Iceberg, and other data sources that Doris supports writing to) through INSERT INTO SELECT, and then performing performance testing on the target tables.

Build TPCDS Test Data Set

The following example quickly builds a TPCDS test data set on Hive using the CTAS statement:

```
CREATE TABLE hive.tpcds100.call_center          PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.call_center                          ;
CREATE TABLE hive.tpcds100.catalog_page         PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.catalog_page                         ;
CREATE TABLE hive.tpcds100.catalog_returns      PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.catalog_returns                      ;
CREATE TABLE hive.tpcds100.catalog_sales        PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.catalog_sales                       ;
CREATE TABLE hive.tpcds100.customer            PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.customer                            ;
CREATE TABLE hive.tpcds100.customer_address    PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.customer_address                    ;
CREATE TABLE hive.tpcds100.customer_demographics PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.customer_demographics               ;
CREATE TABLE hive.tpcds100.date_dim            PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.date_dim                            ;
CREATE TABLE hive.tpcds100.dbgen_version        PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.dbgen_version                       ;
CREATE TABLE hive.tpcds100.household_demographics PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.household_demographics              ;
CREATE TABLE hive.tpcds100.income_band         PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.income_band                         ;
CREATE TABLE hive.tpcds100.inventory           PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.inventory                           ;
CREATE TABLE hive.tpcds100.item               PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.item                               ;
CREATE TABLE hive.tpcds100.promotion           PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.promotion                           ;
CREATE TABLE hive.tpcds100.reason             PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.reason                             ;
CREATE TABLE hive.tpcds100.ship_mode          PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.ship_mode                           ;
CREATE TABLE hive.tpcds100.store              PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.store                               ;
CREATE TABLE hive.tpcds100.store_returns      PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.store_returns                       ;
CREATE TABLE hive.tpcds100.store_sales        PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.store_sales                         ;
CREATE TABLE hive.tpcds100.time_dim           PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.time_dim                           ;
CREATE TABLE hive.tpcds100.warehouse         PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.warehouse                          ;
```

```
CREATE TABLE hive.tpcds100.web_page      PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.web_page                      ;
CREATE TABLE hive.tpcds100.web_returns  PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.web_returns                    ;
CREATE TABLE hive.tpcds100.web_sales    PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.web_sales                      ;
CREATE TABLE hive.tpcds100.web_site     PROPERTIES("file_format" = "parquet") AS SELECT * FROM
tpcds.sf100.web_site                       ;
```

In a Doris cluster with 3 16C BE nodes, creating a TPCDS 1000 Hive dataset takes about 3 to 4 hours.

Overview | Observability

Overview

What Is Observability?

Observability refers to the ability to infer a system's internal state through its external output data. An observability platform collects, stores, and visualizes three core data: Logs, Traces, and Metrics. This helps teams gain a comprehensive understanding of the operational status of distributed systems, supports resource optimization, fault prediction, root cause analysis, improves system reliability, and enhances user experience.

Why Observability Is Becoming Increasingly Important

Observability platforms have several critical use cases that are vital for improving system stability, optimizing operations efficiency, and enabling business innovation.

1. **Fault Diagnosis and Root Cause Analysis:** Real-time monitoring, anomaly detection, and tracing capabilities enable quick identification and analysis of faults. For example, in the financial industry, combining observability with transaction tracing and AI technologies can shorten recovery time and ensure business continuity. It also supports chaos engineering to simulate failure scenarios and validate system fault tolerance.
2. **Performance Optimization and Resource Planning:** Analyzing system resource utilization and response times helps identify performance bottlenecks and dynamically adjust configurations (e.g., load balancing, auto-scaling). Historical data can be used to predict resource needs, optimize cloud resource allocation, and reduce costs.
3. **Business Decision Support:** Correlating IT performance data with business outcomes (such as user retention rates and transaction volumes) helps formulate business strategies. For instance, analyzing user experience metrics can guide product feature improvements.
4. **Security and Compliance Monitoring:** Detects abnormal behaviors (e.g., zero-day attacks) and triggers automated responses to enhance system security. At the same time, log auditing ensures compliance with regulatory requirements.
5. **DevOps Collaboration:** During canary releases, traffic tagging enables tracking of new version behavior. Combined with call chain analysis, it informs release progression and helps developers optimize code performance, reducing production incidents.

The growing importance of observability in recent years is mainly driven by two factors:

1. **Increasing Complexity of Business and IT Systems:** With the development of cloud computing and microservices, business systems are becoming increasingly complex. For example, a GenAI application request might involve dozens of services such as App, service gateway, authentication service, billing service, RAG engine, Agent engine, vector database, business database, distributed cache, message queue, and large model APIs. Traditional methods like checking server status via SSH and analyzing

logs are no longer effective in such complex environments. Observability platforms unify Log, Trace, and Metric data collection and storage, providing centralized visualization and rapid issue investigation.

2. **Higher Requirements for Business Reliability:** System failures have increasingly high impacts on user experience. Therefore, the efficiency of fault detection and recovery has become more critical. Observability provides full data visibility and panoramic analytics, allowing teams to quickly locate root causes, reduce downtime, and ensure service availability. Moreover, with global data analytics and forecasting, potential resource bottlenecks can be identified early, preventing failures before they occur.

How to Choose an Observability Solution

Observability data has several characteristics, and addressing the challenges of massive data storage and analysis is key to any observability solution.

1. **High Storage Volume and Cost Sensitivity:** Observability data, especially Logs and Traces, are typically enormous in volume and generated continuously. In medium-to-large enterprises, daily data generation often reaches terabytes or even petabytes. To meet business or regulatory requirements, data must often be stored for months or even years, leading to storage volumes reaching the PB or EB scale and resulting in significant storage costs. Over time, the value of this data diminishes, making cost efficiency increasingly important.
2. **High Throughput Writes with Real-Time Requirements:** Handling daily ingestion of TB or PB-scale data often requires write throughput ranging from 1–10 GB/s or millions to tens of millions of records per second. Simultaneously, due to the need for real-time troubleshooting and security investigations, platforms must support sub-second write latencies to ensure real-time data availability.
3. **Real-Time Analysis and Full-Text Search Capabilities:** Logs and Traces contain large amounts of textual data. Quickly searching for keywords and phrases is essential. Traditional full-scan and string-matching approaches often fail to deliver real-time performance, especially at this scale—especially under high-throughput, low-latency ingestion conditions. Thus, building inverted indexes tailored for text becomes crucial for achieving sub-second query responsiveness.
4. **Dynamic Data Schema and Frequent Expansion Needs:** Logs originally existed as unstructured free-text logs but evolved into semi-structured JSON formats. Producers frequently modify JSON fields, making schema flexibility essential. Traditional databases and data warehouses struggle to handle such dynamic schemas efficiently, while datalake systems offer storage flexibility but fall short in real-time analytical performance.
5. **Integration with Multiple Data Sources and Analysis Tools:** There are many observability ecosystem tools for data collection and visualization. The storage and analysis engine must integrate seamlessly with these diverse tools.

Given options like Elasticsearch, ClickHouse, Doris, and logging services provided by Cloud vendors, how should one choose? Here are the key evaluation criteria:

1. Performance: Includes Write and Query Performance

Since observability is often used in urgent situations like troubleshooting, queries must respond quickly—especially for textual content in Logs and Traces, which require real-time full-text search to support iterative

exploration. Additionally, users must be able to query near real-time data—queries limited to data from hours or minutes ago are insufficient; fresh data from the past few seconds is needed.

- **Elasticsearch** is known for inverted indexing and full-text search, offering sub-second retrieval. However, it struggles with high-throughput writes, often rejecting writes or experiencing high latency during peak loads. Its aggregation and statistical analysis performance is also relatively weak.
- **Cloud Logging Services** provide sufficient performance through rich resources but come with higher costs.
- **ClickHouse** delivers high write throughput and high aggregation query performance using columnar storage and vectorized execution. However, its full-text search performance lags behind Elasticsearch and Doris by multiples and remains experimental and unsuitable for production use.
- **Doris**, leveraging columnar storage and vectorized execution, optimizes inverted indexing for observability scenarios. It offers better performance than Elasticsearch, with ~5x faster writes and ~2x faster queries. Aggregation performance is up to 6–21x better than Elasticsearch.

2. Cost: Includes Storage and Compute Costs

Observability data volumes are huge, especially Logs and Traces. Medium-to-large enterprises generate TBs or even PBs of data daily. Due to business or regulatory needs, data must be retained for months or years, pushing storage requirements into the PB or even EB range. Compared to business-critical data, observability data has lower value density, and its value decreases over time, making cost sensitivity critical. Additionally, processing massive volumes of data incurs substantial compute costs.

- **Elasticsearch** suffers from high costs. Its storage model combines row-based raw data, inverted indexes, and docvalue columnar storage, with typical compression ratios around 1.5:1. High CPU overhead from JVM and index construction further increases compute costs.
- **Doris** includes numerous optimizations for observability scenarios. Compared to Elasticsearch, it reduces total cost by 50–80%. These include simplified inverted indexing, columnar storage with ZSTD compression (5:1–10:1), cold-hot tiered storage, single-replica writes, time-series compaction to reduce write amplification, and vectorized index building.
- **ClickHouse** uses columnar storage and vectorized engines, delivering lower storage and write costs.
- **Cloud Logging Services** are expensive as Elasticsearch.

3. Openness: Includes Open Source and Multi-Cloud Neutrality

When selecting an observability platform, consider openness, including whether it's open source and multi-cloud neutral.

- **Elasticsearch** is an open-source project maintained by Elastic, available on multiple clouds. Its ELK ecosystem is self-contained and difficult to integrate with other ecosystems, eg. Kibana only supports Elasticsearch and is hard to extend.
- **Doris** is an Apache Top-Level open-source project, supported by major global cloud providers. It integrates well with OpenTelemetry, Grafana, and ELK, maintaining openness and neutrality.
- **ClickHouse** is an open-source project maintained by ClickHouse Inc., available across clouds. While it supports OpenTelemetry and Grafana, its acquisition of an observability company raises concerns about future neutrality.
- **Cloud Logging Services** are tied to their respective clouds, not open source, and differ between vendors, limiting consistent experiences and migration flexibility.

4. Ease of Use: Includes Manageability and Usability

Due to the volume of data, observability platforms usually adopt distributed architectures. Ease of deployment, scaling, upgrades, and other management tasks significantly affects scalability. The interface provided by the system determines developer efficiency and user experience.

- **Elasticsearch's** Kibana web UI is very user-friendly and manageable. However, its DSL query language is complex and hard to learn, posing integration and development challenges.
- **Doris** provides an interactive analysis interface similar to Kibana and integrates natively with Grafana and Kibana (coming soon). Its SQL is standard and MySQL-compatible, making it developer- and analyst-friendly. Doris has a simple architecture that's easy to deploy and maintain, supports online scaling without service interruption, automatic load balancing, and includes a visual Cluster Manager.
- **ClickHouse** provides SQL interfaces but uses its own syntax. Maintenance is challenging due to exposed concepts like local tables vs. distributed tables and lack of automatic rebalancing during scaling. Typically, developing a custom cluster management system is required.
- **Cloud Logging Services** offer SaaS convenience—users don't manage infrastructure and enjoy ease of use.

Based on the above analysis, **Doris** achieves high-performance ingestion and queries while keeping costs low. Its SQL interface is easy to use, and its architecture is simple to maintain and scale. It also ensures consistent experiences across multiple clouds, making it an optimal choice for building an observability platform.

Observability Solution Based on Doris

System Architecture

Apache Doris is a modern data warehouse with an MPP distributed architecture, integrating vectorized execution engines, CBO optimizers, advanced indexing, and materialized views. It supports ultra-fast querying and analysis on large-scale real-time datasets, delivering an exceptional analytical experience. Through continuous technical innovation, Doris has achieved top rankings in authoritative benchmarks such as ClickBench (single table), TPC-H, and TPC-DS (multi tables).

For observability scenarios, Doris introduces inverted indexing and ultra-fast full-text search capabilities, achieving optimized write performance and storage efficiency. This allows users to build high-performance, low-cost, and open observability platforms based on Doris.

A Doris-based observability platform consists of three core components:

- **Data Collection and Preprocessing:** Supports various observability data collection tools, including OpenTelemetry and ELK ecosystem tools like Logstash and Filebeat. Log, Trace, and Metric data are ingested into Doris via HTTP APIs.
- **Data Storage and Analysis Engine:** Doris provides unified, high-performance, low-cost storage for observability data and exposes powerful search and analysis capabilities via SQL interfaces.
- **Query Analysis and Visualization:** Integrates with popular observability visualization tools such as Grafana and Kibana (from the ELK stack), offering intuitive interfaces for searching, analyzing, alerting, and achieving real-time monitoring and rapid response.

doris-observability-architecture

Key Features and Advantages

High Performance

- **High Throughput, Low Latency Writes:** Supports stable ingestion of PB-scale (10GB/s) Log, Trace, and Metric data daily with sub-second latency.
- **High-Performance Inverted Index and Full-Text Search:** Supports inverted indexing and full-text search, delivering sub-second response times for common log keyword searches—3–10x faster than ClickHouse.
- **High-Performance Aggregation Analysis:** Utilizing MPP distributed architecture and vectorized pipeline execution engines, Doris excels in trend analysis and alerting in observability scenarios, leading globally in ClickBench tests.

Low Cost

- **High Compression Ratio and Low-Cost Storage:** Supports PB-scale storage with compression ratios of 5:1 – 10:1 (including indexes), reducing storage costs by 50–80% compared to Elasticsearch. Cold data can be offloaded to S3/HDFS, cutting storage costs by another 50%.
- **Low-Cost Writes:** Consumes 70% less CPU than Elasticsearch for the same write throughput.

Flexible Schema

- **Schema Changes at the Top Level:** Users can use Light Schema Change to add or drop columns or indexes (ADD/DROP COLUMN/INDEX), and schema modifications can be completed in seconds. When designing an observability platform, users only need to consider which fields and indexes are needed at the current stage.
- **Internal Field Changes:** A semi-structured data type called VARIANT is specially designed for scalable JSON data. It can automatically identify field names and types within JSON, and further split frequently

occurring fields into columnar storage, improving compression ratio and analytical performance. Compared to Elasticsearch's Dynamic Mapping, VARIANT allows changes in the data type of a single field.

User-Friendly

- **Standard SQL Interface:** Doris supports standard SQL and is compatible with MySQL protocols and syntax, making it accessible to engineers and analysts.
- **Integration with Observability Ecosystems:** Compatible with OpenTelemetry and ELK ecosystems, supporting Grafana and Kibana (coming soon) visualization tools for seamless data collection and analysis.
- **Easy Operations:** Supports online scaling, automatic load balancing, and visual management via Cluster Manager.

Openness

- **Open Source:** Apache Doris is a top-level open-source project adopted by over 5000 companies worldwide, supporting OpenTelemetry, Grafana, and other observability ecosystems.
- **Multi-Cloud Neutral:** Major cloud providers offer Doris SaaS services, ensuring consistent experiences across clouds.

Demo & Screenshots

We demonstrate the Doris-based observability platform using a comprehensive [demo](#) from the OpenTelemetry community.

The observed business system simulates an [e-commerce website] (<https://opentelemetry.io/docs/demo/architecture/>) composed of frontend, authentication, cart, payment, logistics, advertising, recommendation, risk control, and more than ten modules, reflecting a high level of system complexity, thus presenting significant challenges for observability data collection, storage, and analysis.

The Load Generator tool sends continuous requests to the entry service, generating vast volumes of observability data (Logs, Traces, Metrics). These data are collected using OpenTelemetry SDKs in various languages, sent to the OpenTelemetry Collector, preprocessed by Processors, and finally written into Doris via the OpenTelemetry Doris Exporter. Observability visualization tools such as Grafana connects to Doris through the MySQL interface, providing visualized query and analysis capabilities.

Doris OpenTelemetry Demo

Grafana connects to Doris via MySQL datasource, offering unified visualization and analysis of Logs, Traces, and Metrics, including cross-analysis between Logs and Traces.

- Log

- Trace

- Metrics

While Grafana's log visualization and analysis capabilities are relatively basic compared to Kibana, third-party vendors have implemented Kibana-like Discover features. These will soon be integrated into Grafana's Doris datasource, enhancing unified observability visualization. Future enhancements will include Elasticsearch protocol compatibility, enabling native Kibana connections to Doris. For ELK users, replacing Elasticsearch with Doris maintains existing logging and visualization habits while significantly reducing costs and improving efficiency.

studio-visualization

Log

This document introduces the storage and analysis practices of Logs, one of the core observability components. For an overview of the complete observability solution, please refer to [Overview](#).

Step 1: Estimate resources

Before deploying the cluster, you need to estimate the hardware resources required for the servers. Follow the steps below:

1. Estimate the resources for data writing by the following calculation formulas:
 - $\text{Average write throughput} = \text{Daily data increment} / 86400 \text{ s}$
 - $\text{Peak write throughput} = \text{Average write throughput} \times \text{Ratio of the peak write throughput to the average write throughput}$
 - $\text{Number of CPU cores for the peak write throughput} = \text{Peak write throughput} / \text{Write throughput of a single-core CPU}$
1. Estimate the resources for data storage by the calculation formula: $\text{Storage space} = \text{Daily data increment} / \text{Data compression ratio} \times \text{Number of data copies} \times \text{Data storage duration}$.
2. Estimate the resources for data querying. The resources for data querying depend on the query volume and complexity. It is recommended to reserve 50% of CPU resources for data query initially and then adjust according to the actual test results.
3. Integrate the calculation results as follows:
 1. Divide the number of CPU cores calculated in Step 1 and Step 3 by the number of CPU cores of a BE server, and you can get the number of BE servers.
 2. Based on the number of BE servers and the calculation result of Step 2, estimate the storage space required for each BE server.
 3. Allocate the storage space required for each BE server to 4 to 12 data disks, and you can get the storage capacity required for a single data disk.

For example, suppose that the daily data increment is 100 TB, the data compression ratio is 5, the number of data copies is 2, the storage duration of hot data is 3 days, the storage duration of cold data is 30 days, the ratio of the peak write throughput to the average write throughput is 200%, the write throughput of a single-core CPU is 10 MB/s, and 50% of CPU resources are reserved for data querying, one can estimate that:

compute-storage-integrated mode - 3 FE servers are required, each configured with a 16-core CPU, 64 GB memory, and an 1 100 GB SSD disk. - 30 BE servers are required, each configured with a 32-core CPU, 256 GB memory, and 8 625 GB SSD disks. - S3 object storage space 540 TB

compute-storage-decoupled mode - 3 FE servers are required, each configured with a 16-core CPU, 64 GB memory, and an 1 100 GB SSD disk. - 15 BE servers are required, each configured with a 32-core CPU, 256

GB memory, and 8 680 GB SSD disks. - S3 object storage space 600 TB

Using the storage-compute separation mode, write operations and hot data storage require only 1 replica, which can significantly reduce costs.

Refer to the following table to learn about the values of indicators in the example above and how they are calculated.

| Indicator (Unit) | compute-storage-decoupled | compute-storage-integrated | Description |
|--|---------------------------|----------------------------|---|
| Daily data increment (TB) | 100 | 100 | Specify the value according to your actual needs. |
| Data compression ratio | 5 | 5 | Specify the value according to your actual needs, which is often between 3 to 10. Note that the data contains index data. |
| Number of data copies | 1 | 2 | Specify the value according to your actual needs, which can be 1, 2, or 3. The default value is 1. |
| Storage duration of hot data (day) | 3 | 3 | Specify the value according to your actual needs. |
| Storage duration of cold data (day) | 30 | 27 | Specify the value according to your actual needs. |
| Data storage duration | 30 | 30 | Calculation formula: Storage duration of hot data + Storage duration of cold data |
| Estimated storage space for hot data (TB) | 60 | 120 | Calculation formula: Daily data increment / Data compression ratios * Number of data copies * Storage duration of hot data |
| Estimated storage space for cold data (TB) | 600 | 540 | Calculation formula: Daily data increment / Data compression ratios * Number of data copies * Storage duration of cold data |
| Ratio of the peak write throughput to the average write throughput | 200% | 200% | Specify the value according to your actual needs. The default value is 200%. |

| Indicator (Unit) | compute-storage-decoupled | compute-storage-integrated | Description |
|--|---------------------------|----------------------------|--|
| Number of CPU cores of a BE server | 32 | 32 | Specify the value according to your actual needs. The default value is 32. |
| Average write throughput (MB/s) | 1214 | 2427 | Calculation formula: Daily data increment / 86400 s |
| Peak write throughput (MB/s) | 2427 | 4855 | Calculation formula: Average write throughput * Ratio of the peak write throughput to the average write throughput |
| Number of CPU cores for the peak write throughput | 242.7 | 485.5 | Calculation formula: Peak write throughput / Write throughput of a single-core CPU |
| Percent of CPU resources reserved for data querying | 50% | 50% | Specify the value according to your actual needs. The default value is 50%. |
| Estimated number of BE servers | 15.2 | 30.3 | Calculation formula: Number of CPU cores for the peak write throughput / Number of CPU cores of a BE server / (1 - Percent of CPU resources reserved for data querying) |
| Rounded number of BE servers | 15 | 30 | Calculation formula: MAX (Number of data copies, Estimated number of BE servers) |
| Estimated data storage space for each BE server (TB) | 5.33 | 5.33 | <p>Calculation formula: Estimated storage space for hot data / Estimated number of BE servers / (1 - 30%), where 30% represents the percent of reserved storage space.</p> <p>It is recommended to mount 4 to 12 data disks on each BE server to enhance I/O capabilities.</p> |

Step 2: Deploy the cluster

After estimating the resources, you need to deploy the cluster. It is recommended to deploy in both physical and virtual environments manually. For manual deployment, refer to [Manual Deployment](#).

Step 3: Optimize FE and BE configurations

After completing the cluster deployment, it is necessary to optimize the configuration parameters for both the front-end and back-end separately, so as to better suit the scenario of log storage and analysis.

Optimize FE configurations

You can find FE configuration fields in `fe/conf/fe.conf`. Refer to the following table to optimize FE configurations.

| Configuration fields to be optimized | Description |
|--|---|
| <code>max_running_txn_num_per_db = 10000</code> | Increase the parameter value to adapt to high-concurrency import transactions. |
| <code>streaming_label_keep_max_second = 3600</code>
<code>label_keep_max_second = 7200</code> | Increase the retention time to handle high-frequency import transactions with high memory usage. |
| <code>enable_round_robin_create_tablet = true</code> | When creating Tablets, use a Round Robin strategy to distribute evenly. |
| <code>tablet_rebalancer_type = partition</code> | When balancing Tablets, use a strategy to evenly distribute within each partition. |
| <code>autobucket_min_buckets = 10</code> | Increase the minimum number of automatically bucketed buckets from 1 to 10 to avoid insufficient buckets when the log volume increases. |
| <code>max_backend_heartbeat_failure_tolerance_count = 10</code> | In log scenarios, the BE server may experience high pressure, leading to short-term timeouts, so increase the tolerance count from 1 to 10. |

For more information, refer to [FE Configuration](#).

Optimize BE configurations

You can find BE configuration fields in `be/conf/be.conf`. Refer to the following table to optimize BE configurations.

| Module | Configuration fields to be optimized | Description |
|---------|---|--|
| Storage | <code>storage_root_path =</code>
<code>/path/to/dir1;/path/to/dir2;...;/path/to/dir12</code> | Configure the storage path for hot data on disk directories. |
| - | <code>enable_file_cache = true</code> | Enable file caching. |

| Module | Configuration fields to be optimized | Description |
|------------|---|---|
| - | file_cache_path = [{"path":
"/mnt/datadisk0/file_cache",
"total_size":53687091200, "query_limit":
"10737418240"}],{"path":
"/mnt/datadisk1/file_cache",
"total_size":53687091200,"query_limit":
"10737418240"}] | Configure the cache path and related settings for cold data with the following specific configurations:
path: cache path
total_size: total size of the cache path in bytes, where 53687091200 bytes equals 50 GB
query_limit: maximum amount of data that can be queried from the cache path in one query in bytes, where 10737418240 bytes equals 10 GB |
| Write | write_buffer_size = 1073741824 | Increase the file size of the write buffer to reduce small files and random I/O operations, improving performance. |
| - | max_tablet_version_num = 20000 | In coordination with the time_series compaction strategy for table creation, allow more versions to remain temporarily unmerged |
| Compaction | max_cumu_compaction_threads = 8 | Set to CPU core count / 4, indicating that 1/4 of CPU resources are used for writing, 1/4 for background compaction, and 2/1 for queries and other operations. |
| - | inverted_index_compaction_enable = true | Enable inverted index compaction to reduce CPU consumption during compaction. |
| - | enable_segcompaction = false
enable_ordered_data_compaction = false | Disable two compaction features that are unnecessary for log scenarios. |
| - | enable_compaction_priority_scheduling = false | Low-priority compaction is limited to 2 tasks on a single disk, which can affect the speed of compaction. |
| - | total_permits_for_compaction_score = 200000 | The parameter is used to control memory, under the memory time series strategy, the parameter itself can control memory. |
| Cache | disable_storage_page_cache = true
inverted_index_searcher_cache_limit = 30% | Due to the large volume of log data and limited caching effect, switch from data caching to index caching. |
| - | inverted_index_cache_stale_sweep_time_sec = 3600
index_cache_entry_stay_time_after_lookup_s = 3600 | Maintain index caching in memory for up to 1 hour. |
| - | enable_inverted_index_cache_on_cooldown = true
enable_write_index_searcher_cache = false | Enable automatic caching of cold data storage during index uploading. |
| - | tablet_schema_cache_recycle_interval = 3600
segment_cache_capacity = 20000 | Reduce memory usage by other caches. |
| - | inverted_index_ram_dir_enable = true | Reduce the IO overhead caused by writing to index files temporarily. |
| Thread | pipeline_executor_size = 24
doris_scanner_thread_pool_thread_num = 48 | Configure computing threads and I/O threads for a 32-core CPU in proportion to core count. |
| - | scan_thread_nice_value = 5 | Lower the priority of query I/O threads to ensure writing performance and timeliness. |
| Other | string_type_length_soft_limit_bytes = 10485760 | Increase the length limit of string-type data to 10 MB. |
| - | trash_file_expire_time_sec = 300
path_gc_check_interval_second = 900
path_scan_interval_second = 900 | Accelerate the recycling of trash files. |

For more information, refer to [BE Configuration](#).

Step 4: Create tables

Due to the distinct characteristics of both writing and querying log data, it is recommended to configure tables with targeted settings to enhance performance.

Configure data partitioning and bucketing

- For data partitioning:
 - Enable [range partitioning](#) (`PARTITION BY RANGE(ts)`) with [dynamic partitions](#) (`"dynamic_partition.enable" = "true"`) managed automatically by day.
